there lay at anchor the Dutch fleet of fifteen sail of the line, under the command of Vice-Admiral de Winter; and in order to detain the latter in port until a reinforcement should arrive, he caused repeated signals to be made, as if to the main body of his fleet in the offing; a stratagem which, it was supposed, had the desired effect. At length, about the middle of June, several line-of-battle ships, in detached portions, joined the British admiral, and in a short time thereafter the two fleets were again placed on an equal footing.

But the Venerable having been upwards of eighteen weeks at sea, and during part of that time exposed to boisterous weather, was now in want of almost every description of stores; whilst others of the ships had also suffered by the recent gales, and were besides short of provisions. In these circumstances, the admiral, on the 3d of October, put into Yarmouth roads in order to refit and revictual; having left off the Dutch coast a small squadron of observation under the orders of Captain Trollope of the Russell. But early on the morning of the 9th, the Black Joke hired armed lugger showed herself at the back of Yarmouth sands with the signal for an enemy flying at her mast-head. Immediately all was bustle and preparation, and, by incredible exertions, Admiral Duncan, with eleven sail of the line, was enabled, a little before noon, to weigh and put to sea; directing his course with a fair wind right across to his old station. On the following day, the Powerful, Agincourt, and Isis joined, and on the afternoon of the 11th the advanced ships were near enough to count twenty-two sail of square-rigged vessels at anchor in the Texel. Meanwhile the admiral having received from Captain Trollope information of the course the enemy's fleet was steering, now stood along shore to the southward. At about seven on the morning of the 12th, the Russell, Adamant, and Beaulieu were descried in the south-west, bearing at their mast-heads the signal of an enemy in sight to the leeward; and about half-past eight, a strange fleet, consisting of twenty-one ships and four brigs, made its appearance in the quarter pointed out by the signal.

This was the Dutch fleet, under Vice-Admiral de Winter, consisting of four seventy-fours, seven sixty-fours, four fifty gun ships, two forty-four gun frigates, two of thirty-two guns, two corvettes, four brigs, sloops, and two advice-boats, all which had quitted the Texel at ten o'clock in the morning of the 10th, with a light breeze at east and by north. As soon as Admiral de Winter had learned that the British fleet was approaching, he recalled some ships which he had previously detached, and edged away with the wind at north-west, towards Camperdown, the appointed place of rendezvous. At daylight on the 11th, the Dutch fleet was about nine leagues off the village of Schevenningen, in loose order; but on receiving additional information, Admiral de Winter ordered his captains to their respective stations, and, to facilitate the junction of the ships to leeward, stood towards the land. On the Wykerdens bearing east, distant about four leagues, the Dutch fleet hauled to the wind on the starboard tack, and shortly afterwards discovered the British fleet in the north-north-west; upon which it put about, and as soon as a close line was formed, with frigates and other smaller vessels opposite the openings, the Dutch ships throwing their main-top-sails aback, resolutely awaited the approach of the British.

When the Dutch appeared in sight, the British fleet was, owing to the inequality of the ships in point of sailing, in very loose order. To connect the squadron, therefore, and enable the heavy-sailing ships to take their allotted stations, the admiral made the signal to shorten sail, and bring to on the starboard tack; but observing, soon afterwards, that the Dutch ships were drawing fast in shore, and finding there was no time to be lost in making the attack, he made the signals to bear up, break the enemy's line, and engage them to leeward, each ship her opponent, and also for the van to attack the enemy's rear. In his dispatch the admiral states that his signals were obeyed with the greatest promptitude; but it has been asserted that, owing to the thickness of the weather, the signal to pass through the enemy's line and engage him to leeward was not generally understood during the short time it was displayed, and that hence some uncertainty prevailed in the fleet as to the precise mode of attack. In fact, the admiral perceived that if he waited to form line, there would be no action; and, with equal judgment and boldness, he dispensed with this preliminary arrangement, and notwithstanding the still disunited state of the ships, he hurried them into action as fast as possible. The signal above mentioned was replaced by that for close action, which continued flying for an hour and a half, until it was shot away by the enemy. This signal could not possibly be mistaken.[1]

About forty minutes past twelve o'clock (12th October)

British navy has ever been the support of that liberty which has been handed down to us by our ancestors, and which, I trust, we shall maintain to the latest posterity, and that can only be done by unanimity and obedience. The ship's company, and others who have distinguished themselves by their loyalty and good order, deserve to be, and doubtless will be, the favourites of a grateful country; they will also have, from their individual feelings, a comfort which must be lasting, and not like the fleeting and false confidence of those who have swerved from their duty. It has often been my pride with you to look into the Texel, and see a foe which dreaded coming out to meet us. My pride is now humble indeed. My feelings are not easily to be expressed. Our cup has overflowed, and made us wanton. The all-wise Providence has given us this check as a warning, and I hope we shall improve by it. On Him, then, let us trust, where our only security can be found. I find there are many good men among us: for my own part, I have had full confidence of all in this ship, and once more beg to express my admiration of your conduct. May God, who has thus far conducted you, continue to do so; and may the British navy, the glory and support of our country, be restored to its wonted splendour, and be not only the bulwark of Britain, but the terror of the world. But this can only be effected by a strict adherence to our duty and obedience; and let us pray that the Almighty God may keep us in the right way of thinking. God bless you all." If this speech has but little to recommend it on the score of rhetoric, it has qualities of a nobler kind to compensate for the want of the graces of diction or oratory: it is indeed affecting and impressive in a very high degree; and it is recorded that, among the crew of the Venerable who listened to it, there was not a dry eye when the good admiral had concluded his address.

[1] The following anecdote, which is told by Admiral Sir Charles Ekins (*Naval Battles*, p. 236), shows that the instinct of true valour sometimes supplies the place of knowledge, if not of genius. Captain Inglis of the Belliqueux, sixty-four guns, owing either to long absence from active service, or an inaptitude for the subject sometimes apparent in naval officers, had neglected to make himself competently master of the signal-book; and hence, on the morning of the day of battle, when it became necessary to act with promptitude, in obedience to the signals, he found himself more puzzled than enlightened by it; so, throwing it with contempt upon the deck, he exclaimed in broad Scotch, " Damn me, up wi' the hellem, an' into the middle o't." In this manner he bravely anticipated the remedy in such cases provided by the illustrious Nelson, who, in his celebrated *Memorandum* on the eve of the battle of Trafalgar, observed, that " if a captain should be at a loss, he would not do *very wrong* if he laid his ship alongside of the enemy." In strict conformity with this doctrine, the Belliqueux was carried by her brave and honest captain into the very thickest of the fight, and got very roughly handled by the van of the enemy.

the action commenced, when Vice-Admiral Onslow in the Monarch, which led the advanced or larboard division of the British fleet, cut through the Dutch line between the Haerlem and Jupiter, pouring into each in passing a well-directed broadside; and then leaving the Haerlem to the Powerful, luffed up alongside of the Jupiter, upon which the two ships became warmly engaged. In rounding, the Monarch received the raking fire of the Monnikendam frigate and the Atalanta brig, stationed in the rear or second line. The remaining ships of the larboard division, particularly the Monmouth and Russell, were soon in action with those of the enemy's rear; amongst which the last to surrender was the Jupiter, which had been first engaged. About twenty minutes after the Monarch had passed through the Dutch line, the Venerable, frustrated in her attempt to pass astern of the Vryheid, by the promptness of the States-General in closing up the interval, ran under the stern of the latter, and soon compelled her to bear up; whilst the Triumph, the Venerable's second astern, found immediate employment for the Wassemaer, the second astern of the States-General. In the meanwhile the Venerable had ranged up close on the lee-side of the Vryheid, with which, on the opposite side, the Ardent was also warmly engaged, and, in front, the Bedford, as she cut through the enemy's line astern of the Gelykheid. The Brutus, Leyden, and Mars, not being pressed by opponents, advanced to the assistance of their admiral, and did considerable damage to the Venerable, Ardent, and other ships of the British van. At this time the Hercules, having caught fire on the poop, bore up out of the line, and came drifting near the Venerable to leeward; but although the Dutch crew contrived to extinguish the flames, yet having thrown their powder overboard, they were compelled to surrender their ship to the nearest opponent. The Venerable, which had sustained serious damage, was now obliged to haul off, and to wear round on the starboard tack. As soon as this was observed, the Triumph, which had compelled the Wassemaer to strike her colours, approached to give the finishing blow to the Vryheid, which still persisted in defending herself. At length, from the united fire of the Venerable, Triumph, Ardent, and Director, the three masts of the gallant ship fell over her side, and disabled her starboard guns; upon which the Vryheid dropped out of the line an ungovernable hulk, and then struck her colours. With the surrender of De Winter's ship the action ceased, and the British found themselves in possession of the Vryheid and Jupiter, seventy-fours; Devries, Gelykheid, Haerlem, Hercules, and Wassemaer, sixty-fours; Alkmaar and Delft, fifties; and the frigates Monnikendam and Ambuscade. The victors then hastened to secure their prizes, in order that, before night-fall, they might get clear of the shore.

This battle presented on both sides the singular spectacle of heroic courage and determined perseverance, contrasted with conduct little, if at all, short of downright cowardice or disaffection; and from first to last the opposing forces were, from various causes, pretty nearly equal. Seven Dutch line-of-battle ships quitted the action in order to return home, and nearly as many British seem scarcely to have entered it. The actual combatants, however, maintained the strife with fierce, unflinching valour; and hence the loss on both sides was proportionally severe. That of the British amounted to 203 killed and 622 wounded, while the Dutch had 540 killed and 620 wounded. During the action the latter directed their shot solely at the hulls of their adversaries, and this not until they were so near that scarcely any aim could miss; which accounts for the unusual severity of the loss sustained. On the other hand, the captured ships were all either dismasted outright, or so injured in their masts that most of these fell in the passage home; whilst as to their hulls, they were completely riddled, and only worth bringing into port as trophies of the victory.

If any proof were wanting of the superior efficacy of Admiral Duncan's mode of attack, it would be found, first, in a manly declaration made by the gallant Dutchman, and, secondly, in the practical testimony to its excellence borne by Lord Nelson. "Your not waiting to form a line," said De Winter to Admiral Duncan, "ruined me; if I had got nearer the shore, and you had attacked, I should probably have drawn both fleets on it, and it would have been a victory to me, being on my own coast." And after the battle of the Nile, Nelson, although unacquainted with Lord Duncan, wrote his lordship to tell him how he, Nelson, "had profited by his example." Besides, the British squadron was composed of very indifferent and inadequate ships; many of them having been intended for Indiamen, and otherwise ill conditioned and deficient. Had Lord Duncan's fleet been composed of the same materials as Lord St Vincent's, every Dutch ship would have been taken; and had all the ships imitated the example of their chief, the same result must have followed. Few people are aware of the merits of the chief on that memorable day. When the action ceased, the ships were in nine fathoms water, within five miles of a lee shore, with every appearance of the gale which followed; a situation as critical as it is possible to imagine. And it should also be recollected, that when the Dutch put to sea, the admiral had only been two days in port, after a blockade of nineteen weeks. It was the opinion of Lord Duncan that, upon such occasions, the commander-in-chief should hoist his flag on board of a frigate; and he stated that, if he should ever fight another battle, he would certainly do so. He was often heard to declare that, if his flag had been flying on board of a frigate in this action, not one of the Dutch fleet would have escaped.

No victory was ever more seasonable, none more gratifying to the nation, than that of Camperdown. Politicians beheld in it the annihilation of the marine of Holland, long our most formidable rival on the seas; naval men admired the promptitude, decision, and address displayed by the admiral in approaching to the attack, in circumstances altogether unprecedented; and the people at large were transported with admiration and delight, though they did not very well know why. Hence the honours which were immediately conferred on the admiral received the approbation of all parties. On the 21st of October he was created Lord Viscount Duncan of Camperdown, and Baron Duncan of Lundie, in the county of Angus; his second in command, Vice-Admiral Onslow, was made a baronet; gold medals were struck and presented to the flag officers and captains; and the thanks of parliament were voted to the fleet. A pension of L.2000 per annum was likewise granted to Lord Duncan for his own life, with remainder to the two next heirs of the peerage.

After the victory of Camperdown, Lord Duncan continued to hold the same command until the commencement of 1800, when, being advanced in years, he withdrew from the service, and passed the remainder of his life in retirement, chiefly at his patrimonial residence. At the period of his death, however, which happened on the 4th August 1804, he was, we believe, about to be recalled into active service; and he had signified his determination to obey the call of his country at a season of unexampled difficulty and danger, when his career was terminated for ever by a sudden and fatal illness. In June 1777 he had married Henrietta, daughter of the Right Honourable Robert Dundas, lord president of the Court of Session in Scotland, and father of Lord Viscount Melville; and by this lady he had a large family. Lord Duncan was suc-

ceeded in his titles and estate by his second son, Robert, now Earl of Camperdown.

Lord Duncan was a man as remarkable in appearance as he was distinguished for character and worth. In person he was of a colossal and athletic form, six feet four inches in height, erect in his carriage, and, notwithstanding his great size, graceful in his movements, with a countenance strongly expressive of intelligence and benevolence. In him, singular meekness of disposition, extreme modesty in all that concerned himself, and the most unaffected dignity of mind, were blended with genuine spirit, high professional genius, vigorous and active wisdom, singular alacrity and ability for performing great achievements, and a decided indifference about success, excepting in as far as it might contribute to advance the good of his country. His private character was that of a man most exemplary in all the social relations of life; an affectionate relative, a steady friend, and a pattern of virtue and true piety. Lord Duncan was a most sincere and devout Christian, nor did he ever lose sight of the duties belonging to that character. He encouraged religion by his own practice, and, wherever he held a command, caused the public observance of it to be maintained. Immediately after the victory, which has immortalized his name, was decided, he ordered the crew of his ship to be called together, and, at their head, upon his bended knees, in the presence of the Dutch admiral, who was greatly affected with the scene, he solemnly offered up praise and thanksgiving to the God of battles for having crowned with success the arms of his country. In like manner, when all eyes were upon him, in the cathedral of St Paul's, on the day of general thanksgiving, in December following, his demeanour was so humble and devout, as not only to increase the admiration which his services had otherwise gained him, but to impress on all present a sense of the real dignity as well as importance of religion. In a word, Lord Duncan afforded a conspicuous instance of the truth of the remark, that piety and true courage are naturally allied, and that death loses its terrors to those who have placed their hope beyond it. (Collins's *Peerage*, by Sir E. Brydes; *Naval Chronicle*, vol. iv.; Charnock's *Biographia Navalis;* Chalmers's *Biographical Dictionary*, art. *Duncan;* James's *Naval History of Great Britain*, vol. ii.; Exins's *Naval Battles*, p. 231.) (J. B—E.)

DUNCAN, *Thomas*, one of the most distinguished portrait and historical painters that Scotland has produced, was born at Kinclaven in Perthshire, May 24, 1807. He was educated at the Perth Academy, and afterwards began the study of the law, which, however, he speedily abandoned for the more congenial pursuits of art. Commencing his new career under the directing guidance of Sir William Allan, he early attained distinction as a delineator of the human figure; and his first pictures established his fame so completely, that at a very early age he was appointed professor of colouring, and afterwards of drawing, in the Academy of Edinburgh. In 1840 he produced one of his finest pieces, "Prince Charles Edward and the Highlanders entering Edinburgh after the Battle of Prestonpans." This painting secured his election as an associate of the Royal Academy in 1843. In that same year he produced his no less famous picture of "Charles Edward asleep after Culloden, protected by Flora Macdonald," which, like many other of his pieces, has been often engraved. In 1844 appeared his "Cupid" and his "Martyrdom of John Brown of Priesthill," the last effort of his pencil, with the exception of a portrait of himself. He died at Edinburgh, May 25, 1845.

DUNCANSBY HEAD, a promontory forming the N.E. extremity of Scotland, county of Caithness, about $1\frac{1}{2}$ miles N.E. of John O'Groat's House.

DUNCOMBE, William, younger son of John Duncombe of Stocks, in Hertfordshire, was born at London in 1690. He published in 1722 a translation of Racine's *Athalie*, which was well received by the public, and has gone through three editions. In 1724 he was editor of the works of Mr Needler; in 1735, of the poems of his deceased brother-in-law Mr Hughes, two vols. 12mo; in 1737, of the miscellanies of his younger brother Mr Jabez Hughes, for the benefit of his widow, in one volume 8vo; and in 1745, of the works of the Rev. Samuel Say, in one vol 4to. In 1726 he married the only sister of Mr John Hughes, whom he long survived. In 1734 his tragedy of Lucius Junius Brutus was acted at Drury Lane Theatre. It was published in 1735, and again in 1747. The works of Horace, in English verse, by several hands, were published by him in two vols. 8vo, with notes, in 1757; and a second edition, in four vols. 12mo, with many imitations, appeared in 1762. In 1763 he collected and republished "Seven Sermons by Archbishop Herring, on public occasions, with a biographical preface." He died in February 1769, at the age of eighty.

DUNDALK parliamentary borough and seaport of Irelan ., county Louth, on the S. bank of the Castletown river, near its mouth in Dundalk Bay, 50 miles N. of Dublin. Pop. (1851) 9995. It possesses some good streets, but a great part of the town is filthy and wretched. The parish church is an old and spacious edifice. The other public buildings are—a Roman Catholic chapel, Presbyterian and Methodist meeting-houses, county court-house, infirmary, prison, guildhall, market-house, linen-hall, endowed grammar-school, national schools, and barracks. It has also two breweries, two flour mills, a large distillery, a flax spinning mill, and a pin factory. It carries on a brisk trade, chiefly in agricultural and dairy produce. The municipal government is vested in a bailiff, a recorder, and 16 burgesses. Dundalk returns one member to parliament. The port and harbour of Dundalk have recently been undergoing extensive improvements. The course of the river has been straitened, and the bar and harbour deepened from 5 to 8 feet, so that vessels drawing 16 feet water can now come up to the town. The channel, when completed, will be 150 feet wide at the quays, and 300 at the point. A lighthouse, on the screw-pile principle, has been erected at the bar. Steamers ply regularly to Liverpool three times a-week. On 31st December 1852 the registered shipping belonging to the port was 23 vessels of 1871 tons, and 2 steamers of 844 tons. The number and tonnage of vessels that entered and cleared at the port during 1852 were—inwards, sailing vessels 519, tonnage 35,928; steamers 109, tonnage 77,782: outwards, sailing vessels 224, tonnage 17,074; steamers 105, tonnage 46,235. Market-day Monday. Three newspapers are published in Dundalk. In the reign of Edward II. Dundalk was a royal city;—the last that we read of where a monarch of all Ireland was actually crowned and resided.

DUNDAS, Henry, Viscount Melville, an eminent British statesman, was born about 1741. He was a younger son of the Right Honourable Robert Dundas, lord president of the Court of Session in Scotland; and his mother was a daughter of Sir William Gordon of Gordonston, Bart. He was educated at the High School and University of Edinburgh; and having been brought up to the profession of the law, was admitted a member of the Faculty of Advocates in 1763. He soon distinguished himself at the bar, and rapidly attained to extensive practice. The first promotion he obtained was the situation of one of the assessors to the magistrates of Edinburgh; after which he became successively an advocate-depute and solicitor-general. In 1775, when Sir James Montgomery was appointed lord chief baron, Mr Dundas succeeded him in the office of lord advocate, which situation he continued to occupy until 1783. In March 1777, he was appointed joint keeper of the Signet for Scotland.

From the period of his appointment to the office of lord advocate, Mr Dundas in a great measure abandoned the ordinary practice of the bar, and devoted himself to public business. In 1774 he became a member of parliament, having been elected representative for the county of Edinburgh. Some years afterwards he resigned the representation of the county, and was chosen member for the city of Edinburgh, which he continued to represent until his advancement to the peerage. Although originally returned to parliament in opposition to the ministerial interest, he soon joined the party in power, and became a strenuous supporter of Lord North's measures during the American war. He frequently spoke in the House of Commons; and, notwithstanding the disadvantages of an ungraceful manner and a provincial dialect, he was always listened to with great attention, on account of the clearness of his statements and the weight of his arguments.

In 1782, Mr Dundas was admitted a member of the privy-council, and appointed treasurer of the navy, under the administration of the Marquis of Lansdowne, then Earl of Shelburne;—and he continued to fill that office, and to support the measures of government, until the dissolution of that ministry. During the short coalition administration he was out of place, and made a conspicuous figure in opposing the memorable East India bill, a measure which occasioned the overthrow of the ruling party. Upon that occasion he displayed a knowledge of the affairs of the East India Company, which was evidently the result of much study and laborious investigation. In December 1783, when Pitt became prime minister, Dundas was restored to the same office which he had previously held; and was appointed president of the board of control, under the new East India system. In 1791 he became a member of the cabinet, in consequence of his appointment to the office of principal secretary of state for the home department. The duties of this office he discharged with energy and ability. The volunteer system, which, undoubtedly, contributed much to rouse the spirit of the country during a period of peculiar difficulty and danger, has been ascribed to Dundas. On the accession of the Duke of Portland to the administration of Pitt, he resigned the home department, and became secretary at war. At this time he also held the offices of lord privy seal, and governor of the Bank of Scotland, and enjoyed an extent of patronage in his native country which has seldom or never fallen to the share of any individual, and has been considered by many as more exclusive than can be safely confided to the hands of any one man. For many years he was the intimate friend and coadjutor of Pitt, and took a leading part in all the important measures of his administration. The details of these measures, and Lord Melville's conduct in regard to them, belong to history. In the present article we must restrict ourselves to a general outline of the events of his life, and a short summary of the leading traits of his character.

Upon the resignation of Pitt in 1801, Dundas also resigned his political offices; and in 1802, under the administration of Mr Addington, afterwards Lord Sidmouth, he was elevated to the peerage, by the titles of Viscount Melville and Baron Dunira. The last public situation which he held in the government was that of first lord of the admiralty, to which he was appointed on Pitt's return to power, in the room of Lord St Vincent. It was in his administration of the affairs of the naval department that his lordship incurred the charge relative to the balances of public money remaining in his hands, which produced his celebrated impeachment. We conceive it unnecessary to dwell upon the proceedings of that well-known trial. It is sufficient to say that the House of Lords finally acquitted him of all the charges brought forward in the articles of impeachment exhibited by the Commons; but he had previously resigned all his offices in the administration.

Subsequently to his acquittal, Lord Melville was restored to his seat in the privy-council; but he did not return to office. He sometimes took a share in the debates in the House of Lords; and, in 1810, he brought forward a motion the object of which was to recommend the employment of armed troop-ships, instead of hired transports, for the accommodation of such troops as it might be found expedient to embark in furtherance of the public service. But the greater part of his time was spent in Scotland, where he died suddenly at the house of his nephew, the Right Hon. Robert Dundas, lord chief baron of the Exchequer, May 27, 1811, at the age of seventy-one. He appeared in his usual health for some time preceding, and his death is supposed to have been hastened by the affliction he felt for the loss of his old and valued friend the Lord President Blair, who died a few days before.

In his person Lord Melville was tall, stout, and well formed. In public life he was principally distinguished by his great capacity for business, by the unwearied attention which he paid to the details of all official measures, and by the manliness and decision of his conduct. For many years, as we have already observed, he was the steady friend and firm supporter of the measures of Pitt, to whom he proved a very powerful auxiliary. Whilst he held the offices of treasurer of the navy and first lord of the admiralty, his exertions are admitted to have been attended with great advantage to the public service. He devised several improvements in the details of that department, which have been found of great utility; and, in particular, the regulations with regard to the payment of seamen's wages, transmission of letters, and other matters connected with that branch of the public service, contributed much to the comfort of that class of men, and are highly honourable to the character of their author. In parliament he was a clear, acute, and argumentative speaker. His eloquence, however, was that of a man possessed of strong natural talents, wholly unadorned by literary taste or acquirements; and his speeches produced their effect from the solidity of his arguments, and the fearlessness with which he delivered his opinions, rather than from any powers of oratory or graces of style. The ornamental parts of eloquence, indeed, he seemed to despise, and was satisfied to bring his audience at once to the object he had in view. Political power was his passion, and the bustle of official life was the element in which he loved to move.

In private life his lordship was a most agreeable companion; easy, frank, and convivial; careless of money, even to a fault; always disposed to do kind offices; affectionate in his domestic relations, and greatly beloved by the numerous circle of his friends.

Lord Melville was twice married: first, to Miss Rannie, daughter of Captain Rannie of Melville, by whom he had one son and three daughters. His second wife was Lady Jean Hope, sister of the late Earl of Hopetoun, by whom he left no issue.

Although not, strictly speaking, a literary man, Lord Melville was the author of several pamphlets on political subjects, which were distinguished by his usual sense and knowledge of business. These are, 1. *The Substance of a Speech in the House of Commons, on the British Government and Trade in the East Indies, April* 23, 1793. London, 1813, 8vo. 2. *Letter to the Chairman of the Court of Directors of the East India Company, upon an open Trade to India.* London, 1813, 8vo. 3. *Letters to the Right Honourable Spencer Percival, relative to the Establishment of a Naval Arsenal at Northfleet.* London, 1810, 4to.

DUNDEE, a royal and parliamentary burgh and seaport town of Scotland, county of Forfar, 42 miles N.N.E. from Edinburgh; N. Lat. 56. 2.; W. Long. 3. 2. It is

Dundee. situated on the north side of the river Tay, about 12 miles from its mouth. Pop. (1851) 78,931; and as a considerable increase has since taken place, it may now be estimated at from 90,000 to 100,000. Dundee is thus the third town in Scotland in respect of population. The name applied to it by the earliest writers is Alectum or Taodunum. It was subsequently designated Deidonum, of which the present name is supposed to be a corruption. The early history of the town is involved in obscurity, but it appears to have been a place of importance as early as the twelfth century. Frequent mention is made of it in connection with the disputes regarding the succession to the crown of Scotland; and it was the scene of severe conflicts between the English forces, who invaded the country in the reign of Edward I., and the Scots, under the patriot Wallace, and the other supporters of Scottish independence. Those national feuds were finally extinguished by the union of the crowns in the person of James VI.; but during the protectorate of Oliver Cromwell, Dundee having refused to submit to the republican General Monk, was in 1651 taken by assault, and given up to plunder and massacre. A large booty fell to the republican soldiers, and sixty vessels laden with plunder were sent off to England, but suffered shipwreck, and were totally lost.

The early records of the town were destroyed during the civil wars; but it appears that the first charter constituting it a royal burgh was granted by William the Lion in 1210. Subsequent charters were granted by king Robert in 1327, and James IV. in 1511; and the privileges of the burgh were finally confirmed in 1651, and by act of the Scottish parliament passed in the same year.

The municipal government of the town is vested in a provost, 4 bailies, and 15 councillors, chosen by the parliamentary electors within the royalty. The Dean of Guild, who is elected by the merchant guild, or Guildry incorporation, is likewise a member of the town-council. The subordinate corporations are the Nine Trades, the Three Trades, the Fraternity of Maltmen, and the Trinity House or Fraternity of Masters and Seamen. Since the abolition of exclusive privileges in trading within burgh, the minor corporations have lost much of their importance; but most of them have the privilege of choosing members to represent them in the harbour trust and charitable institutions of the place. Previous to the passing of the Reform act in 1832, Dundee, along with Perth, Forfar, Cupar, and St Andrews, sent only one member to the imperial parliament. By that act the right of sending a representative of its own was conferred upon the town.

Dundee was at one time surrounded by strong walls, and portions of them are yet to be seen. The Cowgate port still stands, and is regarded with veneration as a memorial of George Wishart, the Reformer, who is said to have preached from it in the year 1544, when the plague prevailed in the town, the sick being placed on one side of the wall, and the healthy on the other.

The ground on which the town is built slopes gently towards the river, and is bounded on the north by the Law of Dundee, and the Hill of Balgay. The former rises to the height of 535 feet, and must in warlike times have been a strong position. The walls of a fortification are still to be traced on its summit. The town in general is irregularly built; but within the last 20 or 30 years several new and spacious streets have been opened up. The principal public buildings are the Exchange reading room; the Royal Arch erected by public subscription to commemorate the landing of Queen Victoria in 1844, at a cost of nearly L.8000; the Public Seminaries; and the New Baltic Exchange coffeeroom, a splendid specimen of the Flemish-Gothic style. Of the ecclesiastical buildings the finest are the Town churches, on the north side of Nethergate Street. These were originally reared by David earl of Huntingdon, during the twelfth century, in gratitude for his deliverance from shipwreck, and were dedicated to the Virgin Mary. A portion of the building was destroyed when Monk sacked the town, and a new church was erected upon the site of that portion in 1788. In 1841 the remaining portion of the ancient cathedral was accidentally destroyed by fire, and was replaced by two elegant churches in the pure Gothic style. The square tower or old steeple is the only part of the original edifice which still remains. It is a fine building of massive proportions, and 156 feet in height. Besides these, there are St Andrew's church, King Street, a neat building with a spire 139 feet high; St Paul's Free Church, on the south side of Nethergate Street, a fine structure, surmounted by a light and tasteful spire 160 feet high; and St Paul's Episcopal church, Castlehill, a very handsome edifice, adorned with a lofty spire about 210 feet in height. Some of the other places of worship are neat and tasteful buildings. The Established Church possesses 8 of these; the Free Church, 10; United Presbyterians, 6; Congregationalists, 4; Episcopalians, 2; Roman Catholics, 2; and the other religious bodies have about 10 places of worship.

Among the other public buildings deserving of notice are the Town-house surmounted by a spire of handsome proportions; the Custom-house; the New Infirmary, with accommodation for upwards of 300 patients; the county prison and bridewell; Dudhope Castle and barracks. The inhabitants enjoy the privilege of recreation on the top of the Law. Besides the Magdalen Yard, a fine pleasure-ground at the west end of the town, the bleaching green and barrack park have been lately opened as places of public recreation; and a new pleasure-ground has also been formed at the east end of the town, to which skating and curling ponds are attached.

The charitable and benevolent institutions are numerous. The principal of these are the royal infirmary and dispensary, the royal lunatic asylum, the orphan institution, and industrial or ragged schools. There are likewise several mortifications for purposes of education, and the support of aged and infirm persons.

Within a comparatively recent period a number of important public undertakings have been completed. The Dundee and Newtyle railway was opened for traffic in 1826; the Dundee and Arbroath railway in 1838; and the Dundee and Perth railway in 1847. By means of these railways, and of the Edinburgh, Perth, and Dundee railway, which joins the Dundee and Arbroath railway by means of a ferry and branch line at Broughty Castle, 4 miles east from the town, Dundee has direct communication with all parts of the kingdom. There are two gas-light companies, each of them with a capital of about L.50,000 invested in their works and apparatus. The Dundee water company was formed in 1846. Its capital is about L.130,000. Its reservoirs are situated in the parish of Monikie about 10 miles distant from the town; and from these an abundant supply of water has been procured.

The most important of the public works are the harbour and docks. Previously to 1815 the harbour was of very limited extent. In that year an act of parliament was obtained for enlarging it, and erecting a wet dock of $6\frac{1}{4}$ acres (King William's), a tide harbour of $4\frac{3}{4}$ acres, graving dock, and other accommodation suitable for the increasing trade of the port. The plan was afterwards greatly enlarged, embracing new docks (Earl Grey's of $5\frac{1}{4}$ acres, and Victoria dock of $14\frac{1}{2}$ acres), patent slip, careening-beach, and additional tide harbours. The Victoria dock, though for some years open to vessels, is not quite completed. The quays are wide, and afford convenient berthage for about 70 vessels. On the south quay of Earl Grey's dock is erected a large crane capable of raising 30 tons. It is used chiefly for lifting the boilers and heavy machinery of steam-vessels.

Dundee.

Besides the ordinary branches of shipbuilding, the building of iron vessels is carried on at the port. Owing to the increased burden of the vessels now employed in the trade of the place, and the greater depth of water required by them, additional works at the harbour are projected. The cost of the docks and harbour may be stated at L.600,000.

The number and tonnage of vessels entered at the harbour for the year ending 31st May 1854 was as follows:—

Vessels in foreign trade,	682	Register tonnage,	110,637
... coasting trade,	1755	...	158,334
... river trade,	633	...	28,262
Total,	3070		297,233

The following statement shows the progressive increase in the harbour and shipping dues. It was—

In 1780	L.305
1795	965
1805	1272
1815	4400
1835	11,908
1854	23,402

The staple trade of Dundee is the manufacture of linen and hempen fabrics, chiefly of the coarser descriptions. The manufacture of linens appears to have been introduced from Germany in the beginning of last century. Insignificant in extent at first, it gradually increased till the close of that century, when, machinery having been applied to the spinning of flax, a great impulse was given to it. Spinning mills were erected, and of these there are now about sixty in Dundee and its immediate neighbourhood. Handspinning has been entirely superseded by mill-spinning. The coarser fabrics are still woven in hand-looms; but there are now six or seven large power-loom factories, and some smaller ones. The chief articles of manufacture are sheetings, sail-cloth, drills, dowlas, sacking, and bagging. Nearly one-half of the quantity made is sent to London, Manchester, Glasgow, and Leeds, for home consumption. The remainder is exported either directly or indirectly to foreign countries. The manufacture of jute carpeting is also now carried on to a large extent. The number of persons employed in the linen trade of the place is estimated to be from 20,000 to 25,000.

The quantity of flax, hemp, codilla, and jute, imported for the year ending 31st May 1854, was as follows:—

At the harbour	54,341 tons.
By railway	11,406
Total,	65,747

The quantity of linen goods sent away for exportation and home consumption for the same period was as follows:—

Linens of all descriptions shipped at the harbour	421,432 pieces.
By railway	686,110
Total,	1,107,542 pieces.

Assuming the value of the material at L.30 per ton, its total value used in manufactures will be L.1,872,410.

Assuming the value of the goods manufactured to be 60s. per piece, their gross value will be L.3,322,626; and, on this assumption, the balance of L.1,450,216 represents the cost of the manufacture, including wages, the rents of premises and machinery employed in it, and the profits of the manufacturers.

From the foregoing statements, some idea may be formed of the rapid increase of the town in commerce, wealth, and population. Dundee is now the principal seat of the linen trade of the United Kingdom, and its fabrics are to be met with in all quarters of the world. In proof of the prudential habits of the people, it may be mentioned that a national security savings-bank, opened in 1838, now contains upwards of L.70,000, lodged by 4632 depositors.

Dundee was remarkable at an early period for its ardent attachment to the principles of the Reformation, and it was long designated the "Geneva of Scotland." Many eminent ministers of the gospel laboured here, amongst whom may be mentioned John Willison and Dr Robert Small. It is the native place of the Fletchers and Scrimgeours, of Admiral Viscount Duncan, and George Dempster of Dunnichen.

The country surrounding the town is fertile and well cultivated; and has shared largely in its prosperity, the rents having increased much, and the value of the land being augmented in proportion. With the natural advantages which it enjoys, and the energy and enterprise for which the inhabitants are distinguished, Dundee may be expected to maintain the position which it now holds among the commercial towns of the British empire.

Dunfermline.

DUNFERMLINE, a royal burgh of Scotland, situated in the western district of the county of Fife, 15 miles N.W. of Edinburgh, in W. Long. 3. 27. 11.; N. Lat. 56. 5. 3. The town is built on an extensive eminence, having a pretty steep and uniform declivity towards the south, and likewise declining into a ravine on the west, which divides the more ancient part of the town from the extensive suburb of Pittencrieff. This ravine is crossed by an earthen mound, on which an excellent street is built, and is equal to the second-rate streets of the metropolis, and surpasses in its uniformity, and the appearance of its shops, the principal streets of most country towns. The town is situated about 270 feet above the level of the sea, and about three miles distant from Limekilns, the nearest place on the coast. It may be described as consisting of one principal thoroughfare, and several parallel streets stretching from east to west, near the top of the eminence on which the town is built, which is intersected at right angles by streets running up and down the hill, terminating in a plain both at the top and bottom. From its elevated situation, the prospect all around is very extensive. Seen from the south or west, the town has a very noble appearance, principally from its irregular outline, and the many prominent objects, such as steeples and public buildings, with which the whole is adorned; and it is here and there interspersed with gardens and trees, which give it a very pleasing and picturesque appearance, flanked as it is on the west by the extensive parks of Pittencrieff, and on the east by the grounds of Viewfield and Comely Park. The building most worthy of notice is the Abbey Church, which has been erected on the site of the Church of the Holy Trinity, built by Malcolm Ceanmore, about the middle of the eleventh century. This was demolished by Edward I. on the 10th February 1304, and subsequently at the Reformation, on the 28th March 1560. However at the latter period, the nave escaped destruction, and was used as a place of worship till September 1821, when the new church was opened for divine service. It is a splendid edifice, in the Gothic style. Over the centre of the cross is erected a square tower ninety feet high, terminating in a flat roof, round the four sides of which, in open hewn work, are the words "King Robert the Bruce," in capital letters four feet in height, surmounted by royal crowns and lofty pinnacles on the four corners. The old church forms a very fine entrance to the new; and the extensive repairs recently made on it by the Commissioners of Woods and Forests have rendered it still more impressive. It is of various orders of architecture, accordant with the different ages in which it has been altered and repaired. The interior of the New Abbey Church is extremely elegant. Its tower and galleries are supported by magnificent piers, moulded on the solid mason-work with Roman cement, into small columns, which form the aggregate pier, the capitals of which are adorned with exquisite imitations of foliage. The ribs of the arches composing the different roofs and the central ornaments are in the purest style, and,

seen from any point, the effect of the whole is at once magnificent and pleasing. Exactly below the pulpit, which is of wainscot, and in the Gothic style, lie the remains of Robert Bruce; and in the north transept lie seven other kings, two queens, and numbers of the nobility. Besides the old church and steeple, the remains of the ancient buildings consist of the south-west wall of the palace, which hangs on the brink of a deep hollow, through which runs a small stream, a building over a gate, probably the principal entrance to the palace yard, the south wall of the Refectory or Fraters Hall, and a large window of elegant workmanship. There are likewise some slight traces of Malcolm Ceanmore's tower, which formed the original nucleus of the town. The Guildhall, which was erected in 1808, is an edifice of Roman architecture, with a spire 132 feet in height. It consists of a large hall intended for meetings of guildry. It has lately been acquired by the county, and is used for sheriff and justice-of-peace courts and other public offices.

The town-house is a narrow building. It now contains the burgh-court rooms, the council-hall, and chambers for the town-clerk, the prison having been removed and a superior modern prison built in the outskirts of the town. In the same locality there has also been erected a commodious and well arranged poor-house, with a fever hospital adjoining. The council-hall is adorned with some good paintings, and is surmounted by a spire.

The educational institutions of the town are numerous, consisting of the High School, under the patronage of the town-council, and partially endowed; the Commercial Academy, the property of the guildry; the Maclean Schools, built and endowed by bequest of the late Rev. Allan Maclean, a minister of the parish; the Free Abbey Church Schools, and several others—all well conducted; but for a complete educational course there is still wanting one good academy taught by several masters for the different branches.

A school of art has lately been instituted in connection with the Board of Trade Department of Science and Art, and for its accommodation a tasteful and appropriate building has been erected by public subscription.

The linen trade is of considerable antiquity in Dunfermline. It began originally with ticks and checks. The first table-linen manufactured here was a kind called huckaback; this was followed in course of time by damask, the richest and most ingenious kind of table-linen, which has been for the last century improving in quality and pattern, and is still continuing to be improved. The value of table-linens, diapers, and table-covers annually manufactured here is estimated at about L.450,000. Power looms for the weaving of all descriptions of diaper, and some varieties of damask, have been in use for several years. There are now two power-loom factories, employing about 700 hands.

At one period there were eight flax-spinning mills here; they have now dwindled to *one*, and that chiefly for the production of sewing thread; the yarns used in the trade being now imported from various places in England, Scotland, and Ireland, chiefly from the two latter. The decline of the flax-spinning trade is attributed to the want of facility for the importation of the bulky raw material. A proposal is now on foot for connecting Dunfermline by railway with a harbour at Queensferry, about 5½ miles distant. Were this scheme carried out it would give the town the advantage of a shipping port, and probably re-establish in it the trade of flax-spinning.

Extensive works are in operation in the immediate vicinity of the town for the manufacture of malleable iron. They were originally erected by a joint-stock company, and are now the property of the Weardale Iron Company.

This town is remarkable as having been the theatre in which the principal dissents from the Established Church have taken their rise; that, namely, of the Seceders under Ralph Erskine, and that of the Relief body under George Gillespie. It is amply supplied with places of worship in connection with the various denominations; there being three congregations of the Established Church, three of the Free Church, four of the United Presbyterian, and one each of the Independent, Baptist, Episcopalian, Morrisonian, Roman Catholic, and Rowite persuasions.

The population in 1851 was 8577 within the municipal boundaries; and 13,836 within the parliamentary bounds.

DUNGANNON, a municipal and parliamentary borough and market-town of Ireland, county Tyrone, standing on the acclivity of a hill, 8 miles from Lough Neagh. Pop. (1851) 3854. It consists of a square, with several diverging streets, and is generally well built. The chief public buildings are the parish church, Roman Catholic chapel, two Presbyterian, and two Methodist meeting-houses, court-house, bridewell, market-house, savings-bank, fever hospital, temperance hall, and an endowed school. Manufactures—chiefly linens and coarse earthenware. Market-day Thursday. Dungannon returns one member to parliament.

DUNGARVAN, a municipal and parliamentary borough and seaport-town of Ireland, county of Waterford, and 25 miles W.S.W. from the town of that name. It is situated in the bay of Dungarvan at the mouth of the Colligan, which divides the town into two parts, and is crossed by a bridge with a single arch. The eastern portion is called Abbey-side. The town generally has a neat appearance, and has recently been much improved by the exertions of the Duke of Devonshire. In summer it is resorted to for sea-bathing. The principal public buildings are the parish church, two Roman Catholic chapels, a convent, fever hospital, union workhouse, market-house, and an ancient castle now used as barracks. Pop. (1851) 6417, chiefly engaged in the fisheries. The principal exports consist of grain, butter, and cattle. Vessels of more than 250 tons burden cannot come to the quay. Market-day Saturday. The borough returns one member to the imperial parliament; constituency (1851) 314.

DUNKELD, a burgh of barony and market-town of Scotland, county of Perth, on the north bank of the Tay, 15 miles N.N.W. from Perth. The river is here crossed by a fine bridge of seven arches, built in 1809, and communicating with Little Dunkeld, a suburb on the opposite side of the river. Pop. (1851) 1104. The situation of Dunkeld is truly romantic, and the surrounding scenery highly picturesque. It stands in the centre of a valley surrounded by mountains of considerable elevation, which are wooded to the summit. With the exception of one new street, the houses are generally old and mean. The most striking object in the town is the ancient and venerable cathedral—an edifice partly Saxon and partly Gothic; the remains of which are both extensive and in good preservation. The centre of the nave is 120 feet by 60, the walls 40 feet high, and its aisles 12 feet wide. It is now roofless; but the choir was rebuilt and handsomely fitted up by the late Duke of Atholl, and is now used as the parish church. On the north side of the choir is the charter-house, built by Bishop Lauder in 1469; beneath which is the sepulchral vault of the Atholl family. In the porch of the church is the tomb of Alexander Stuart Earl of Buchan, better known as the Wolf of Badneoch, who died in 1384. Here, so early as 729, the Culdees had a monastery, which was converted into a cathedral by David I. in 1127. Among the bishops of Dunkeld were *Bruce's* bishop Sinclair, Gavin Douglas the translator of the *Æneid*, and Henry Guthrie author of "Memoirs of Scottish Affairs from 1637 to the death of Charles I." Immediately behind the cathedral stands the ancient mansion of the dukes of Atholl. A magnificent new mansion was commenced by the late duke, but at his death in 1830 its progress was suspended. The magnificent grounds of the ducal residence are not surpassed in extent and beauty by any in Scotland. The larch woods alone cover an area of 11,000 acres. The late duke

planted about twenty-seven millions of these trees, besides several millions of other kinds. The site of Birnam Wood, so famous for its connection with the fate of Macbeth, is about three miles S. of Dunkeld. The Braan, a mountain stream which falls into the Tay, nearly opposite to Dunkeld, forms a magnificent cascade of 80 feet in height, and known as the "Rumbling Brig," from a narrow bridge made by the fall of two rocks across the stream. The stream has a second fall which, but for the other, would be deemed superb.

DUNKERQUE, DUNQUERQUE, or DUNKIRK, a strongly fortified seaport-town of France, capital of an arrondissement in the department of the Nord, is situated on the E. shore of the Straits of Dover, 174 miles from Paris, and 50 miles from Lille; N. Lat. 51. 2.; E. Long. 2. 23. Pop. (1851) 26,886.

Dunkerque is a handsome and well-built town, with an air of great bustle and commercial prosperity. Its principal public squares, the Place Jean Bart and the Champ-de-Mars, are wide and spacious, planted with trees and adorned with statues. The public buildings worthy of notice are the church of St Eloi, a motley edifice, partly Gothic and partly Corinthian in architecture; the barracks and military magazines, the beffroi, the lighthouse, and the theatre. The trade of Dunkerque is already very considerable, and has increased with great rapidity ever since the town was made a free port in 1826. The chief articles of manufacture are soap, beet-root sugar, starch, and leather. There are also some important shipbuilding-yards and iron-foundries. The fisheries of the coast are valuable and extensive. Dunkerque possesses tribunals of first instance and of commerce, a chamber of commerce, a custom-house, and a school of navigation; and the consuls of various foreign countries reside in the town.

Dunkerque traces its existence as far back as the days of St Eloi, who is said to have founded on the site of the present town a chapel round which a small village speedily sprang up. In the tenth century Baldwin III., Count of Flanders, raised the village to the rank of a town: and in the sixteenth century Charles V. built a fort for the protection of the harbour, no traces of which, however, now exist. In 1558 the English, who had for some time held possession of the town, were expelled from it by the French, who in the ensuing year surrendered it to the Spaniards. In the middle of the seventeenth century it once more passed into the hands of the French, who, after a few years' occupation of it, again restored it to Spain. In 1658 it was retaken by the French and made over to the English. After the restoration, Charles II. was compelled by his extravagance to sell the town to the French king Louis XIV., who fortified it. In 1793 it was attacked by the English under the Duke of York, who, however, was compelled to retire from before its walls with severe loss.

DUNKERS (First-day or German Baptists), a sect founded by Alexander Mack in Schwarzenau about the year 1708. The origin of the name is unknown. Having been persecuted in Germany, they fled to Holland and thence to America, where they founded their first church in Germantown in 1723. They repudiate the practice of judicial oaths, mercantile interest, and warfare. Celibacy is not enjoined, but the sexes dwell apart, and have separate divine service. Their mode of life is simple, and they confine themselves to vegetable diet. They believe in the doctrines of human merit and works of supererogation; and get rid of eternal punishments by the hypothesis of periodical purgations. Their liturgy is simple. They celebrate the Lord's Supper at night with a love feast, the kiss of charity, washing the feet, and striking the hand as a pledge of mutual confidence. By their industry they are generally in comfortable circumstances, and have about 50 churches and 40 preachers. Dr Klose estimates their numbers at 30,000.

DUNMANWAY, a market-town of Ireland, county of Cork, on the Brandon, near the junction of the three streams which form that river, 33 miles W. by S. of Cork. Pop. (1851) 2222. It has two Episcopalian churches, a Roman Catholic and a Methodist chapel, and a bridewell. The linen trade, formerly rather flourishing, has declined; but tanning and brewing and the corn trade are actively carried on.

DUNMOW, GREAT, a market-town and parish in the county of Essex, on the river Chelmar, 38 miles from London. It is a town of very ancient date, supposed to be the Cæsaromagus of the Romans; and here remains of the road to Colchester, constructed by that people, are still visible. Pop. of parish (1851) 3235, chiefly engaged in the manufacture of sacking and coarse cloth. Market-day Saturday. Near it is Little Dunmow, remarkable for the ancient right which a happy couple have to demand a flitch of bacon at the end of a year from their marriage.

DUNNAGE, in *Commercial Navigation*, denotes loose wood, boughs, or other materials, laid above the ballast of a ship, to preserve the cargo from injury.

DUNNING, JOHN, LORD ASHBURTON, an eminent English lawyer, was the second son of Mr John Dunning of Ashburton, Devonshire, an attorney. He was born at Ashburton Oct. 18, 1731, and was educated at the free grammar-school of his native place, where he soon distinguished himself in classical literature and mathematics. On leaving school he was taken into his father's office, where he remained until the age of nineteen, when he was sent to the Temple. At the bar he came very slowly into practice. In 1762 he was employed to draw up *A Defence of the United Company of Merchants of England trading to the East Indies, and their Servants, particularly those at Bengal, against the Complaints of the Dutch East India Company to His Majesty on that subject;* and the masterly style which characterized the document procured him at once reputation and emolument.

In 1763 he distinguished himself as counsel on the side of Wilkes; and his professional business from that period gradually increased to such an extent, that in 1776 he is said to have been in the receipt of nearly L.10,000 per annum. In 1766 he was chosen recorder of Bristol, and in December 1767 he was appointed to the office of solicitor-general. This latter appointment he held till May 1770, when he retired, along with his friend Lord Shelburne. In 1771 he was presented with the freedom of the city of London. From this period he was considered as a regular member of the opposition party, and distinguished himself by many able speeches in parliament. He was first chosen member for Calne in 1768, and continued to represent that burgh until he was promoted to the peerage. In 1782, when the Marquis of Rockingham became prime minister, Dunning was appointed chancellor of the duchy of Lancaster; and about the same time he was advanced to the peerage, by the title of Lord Ashburton. He died while on a visit to Exmouth, Aug. 18, 1783.

The person of Lord Ashburton was by no means agreeable or prepossessing. He was a short, thick man, with a sallow countenance, a constant shake of the head, and a hectic cough, which frequently interrupted the stream of his eloquence. His oratory, however, was at once fluent, elegant, and argumentative, and he possessed a sound knowledge of the laws, and of the theory of our constitution. His language was pure and classical, yet peculiar to himself; and he had a great fund of wit and humour. His disposition was originally timid, but this defect he overcame by practice, as he became more familiar with forensic habits. Of the great extent of his practice some notion may be formed from the fortune he left behind him, which was all earned by his own exertions, and amounted to no less a sum than L.180,000.

Sir William Jones has pronounced a splendid eulogium

on the character of Lord Ashburton. "His language," says that accomplished scholar, "was always pure, always elegant; and the best words dropped easily from his lips into the best places, with a fluency at all times astonishing, and, when he had perfect health, really melodious. His style of speaking consisted of all the turns, oppositions, and figures, which the old rhetoricians taught, and which Cicero frequently practised, but which the austere and solemn spirit of Demosthenes refused to adopt from his first master, and seldom admitted into his orations, political or forensic. That faculty, however, in which no mortal ever surpassed him, and which all found irresistible, was his wit. This relieved the weary, calmed the resentful, and animated the drowsy; this drew smiles even from such as were the objects of it; scattered flowers over a desert; and, like sun-beams sparkling on a lake, gave spirit and vivacity to the dullest and least interesting cause. He was endued with an intellect sedate yet penetrating, clear yet profound, subtle yet strong. His knowledge, too, was equal to his imagination, and his memory to his knowledge."

Besides the *Answer to the Dutch Memorial*, Lord Ashburton is supposed to have assisted in writing a pamphlet on the law of libel, and to have been the author of *A Letter to the Proprietors of East India Stock, on the subject of Lord Clive's Jaghire, occasioned by his Lordship's Letter on that Subject*, 1764, 8vo. His lordship was at one time suspected of being the author of the celebrated *Letters of Junius*. (See Chalmers's *Biog. Dict.*, and Sir W. Jones's *Works*, vol. iv.)

DUNOON, a favourite watering-place in Argyleshire, on the Firth of Clyde, 9 miles W. of Greenock. It has an excellent pier, and many well-built houses and elegant villas. Numerous steamers from Glasgow and other places touch there. The castle was once a royal residence and a strong fortress, of which no remains except a wall are now visible. Pop. (1851) 2229.

DUNS, JOHN (commonly styled Duns Scotus), a schoolman of the highest reputation, is said to have been born in the year 1274, but the place of his birth has been long and much disputed. Dempster has asserted the claims of Scotland by twelve arguments;[1] but a less formidable number might perhaps have been sufficient. The designation *Scotus*, which is commonly added to his name, evinces him to have been a native either of Scotland or of Ireland; but the pretensions of the latter country cannot be supported by the authority of a single early writer. Wadding and other Irish authors who claim him as their countryman, persuade themselves that he was born at *Dunum*, or Downpatrick, and must thence have derived the name of Duns;[2] but this is obviously a mere conjecture, unsupported by tradition, and carrying with it no great plausibility. Leland claims him as an Englishman, on the authority of certain manuscript copies of his works, preserved in the library of Merton College, and bearing a colophon which describes him as born at the village of Dunstane in the county of Northumberland.[3] But if this had been the place of his birth, his surname ought to have been Dunstane. It apparently belongs to the class of local surnames, or those derived from places of birth or habitation; and we have little or no hesitation in supposing him to have been a native of Dunse in the county of Berwick. This surname is still to be found in Scotland. He is mentioned as a native of Scotland by Trithemius,[4] and likewise by Paulus Jovius, Sixtus Senensis, Possevin, and many other writers of various countries. We are told that when a boy he became accidentally known to two Franciscan friars, who, finding him to be a youth of very extraordinary capacity, took him to their convent at Newcastle, and afterwards persuaded him to become one of their fraternity. From thence he was sent to Oxford, where he became a fellow of Merton College, and professor of divinity; but it appears that he had likewise studied at Paris. His lectures were frequented by a prodigious concourse of students. His fame was now become so universal, that the general of his order removed him to Paris, that the students of that university might also have the benefit of his lectures. He went to Paris in the year 1304, where he is said to have been honoured first with the degree of bachelor, then of doctor of divinity, and in 1307 to have been appointed regent of the divinity schools; but as he had taught divinity at Oxford, he must previously have taken at least one degree in that faculty. During his residence at Paris arose the famous controversy about the immaculate conception of the Virgin Mary. Albertus Magnus maintained that she was born in original sin. Scotus advanced two hundred arguments in support of the contrary opinion, and convinced the university of Paris that she was really conceived immaculate. This important nonsense, however, continued to be disputed till 1496, after the council of Basel, when the university of Paris made a decree, that no student who did not believe the immaculate conception should be admitted to a degree. Duns had not been above a year at Paris, when the same general of the Franciscans ordered him to remove to Cologne, where he was received with great pomp and ceremony by the magistrates and nobles of that city, and where he died of apoplexy soon after his arrival, in 1308, in the thirty-fourth year of his age. Some writers have reported that he was buried in an epileptic fit, and that, upon removing his bones, he appeared to have turned himself in his coffin; or, according to another account, to have gnawed the flesh from one of his arms. The genius of this renowned schoolman, who obtained the appellation of *Doctor Subtilis*, or the Subtle Doctor, reflects no inconsiderable lustre on the nation to which he belonged: he maintained a reputation almost unrivalled till the scholastic theology and scholastic philosophy were finally exploded. His followers, who were called Scotists, opposed the opinions of the Thomists, or followers of St Thomas Aquinas. An edition of his works, accompanied by a life of the author by Luke Wadding, was published at Lyon in 12 volumes folio. See SCOTISTS, and SECOND PRELIMINARY DISSERTATION to this work, § iii.

DUNSE, a burgh of barony and market-town of Berwickshire, Scotland, 15 miles W. from Berwick, and 44 miles S.E. from Edinburgh. Besides the town-house, a modern Gothic building, it contains a parish church, a Free church, 3 United Presbyterian chapels, and chapels for Episcopalians and Independents. There are fairs for cattle in June, August, and November; for wool in July; and for sheep in March, May, July, and September. The sheriff-courts for the county are held here. Dunse was the birth-place of Duns Scotus; and in the parish were born the Rev. Thomas Boston and Dr M'Crie. Near it is Dunse Law, which still retains vestiges of its occupation by General Leslie in 1639. Pop. (1851), 2567.

DUNSTABLE, a market-town of Bedfordshire, in the parish of Dunstable, and hundred of Manshead, 33 miles N.W. from London (47½ by N.-Western railway), and 18 miles S.S.W. from Bedford. It is situated on the ancient Watling and Icknield streets, and is generally supposed to have been the *Magiovinium* of the Romans. It rose into importance after the erection (by Henry I.), in 1131, of a priory of black canons, of which the present parish church formed part. The present building presents a remarkable

Dunstan. fine front in the mixed Norman style; and, besides several ancient brasses, contains the "Last Supper" by Thornhill. There are also chapels for Baptists and Wesleyan Methodists, and several schools and almshouses. Many of the females are engaged in the manufacture of straw-plait. There is a weekly market on Saturday, besides quarterly fairs principally for sheep. The neighbouring chalk downs furnish a breed of larks of unusual size. Pop. (1851) 3589.

DUNSTAN, Saint, a famous archbishop of Canterbury. He was descended from a noble family in Wessex, and educated in the abbey of Glastonbury, where he studied so hard that he was seized with a violent fever, which brought him to the very point of death. When the whole family were standing about his bed, dissolved in tears, and expecting every moment to see him expire, an angel came from heaven in a dreadful storm, and gave him a medicine which restored him to perfect health in a moment. Dunstan immediately started from his bed, and ran with all his speed towards the church to return thanks for his recovery; but the devil met him by the way, surrounded by a great multitude of black dogs, and endeavoured to obstruct his passage. This would have frightened ordinary boys, but it had no effect whatever upon Dunstan, who, having pronounced a sacred name, and brandished his stick, put the devil and all his dogs to flight. The church doors being shut, an angel took him up in his arms, conveyed him through an opening in the roof, and set him softly down on the floor, where he performed his devotions. After his recovery, he pursued his studies with the greatest ardour, and soon became a perfect master in philosophy, divinity, and music; painting, writing, and sculpture; besides working in gold, silver, brass, iron, and other metals. Whilst still young he entered into holy orders, and was introduced by his uncle Athelm, archbishop of Canterbury, to King Athelstan, who, being charmed with his person and accomplishments, retained him at his court, and employed him in many great affairs. At leisure hours he used to entertain the king and his courtiers with playing on the harp, or some other musical instrument; and now and then, by way of variety, he wrought a miracle, which gained him great admiration. But his old enemy the devil was much offended at this, and prompted some envious courtiers to persuade the king that his favourite was a magician; a story which that prince too readily believed. Dunstan, however, having discovered by the king's countenance that he had lost his favour, resolved to resign rather than be dismissed, and accordingly retired from court to another uncle, who was Bishop of Winchester. This good prelate prevailed upon his nephew to forsake the world and become a monk; and Dunstan retired to a little cell built against the church wall of Glastonbury. Here he slept, studied, prayed, meditated, and sometimes amused himself with forging several useful things in brass and in iron. One evening as he was working very busily at his forge, the devil, putting on the appearance of a man, thrust his head in at the window of his cell, and asked him to make something or other for him. Dunstan was so intent upon his work that he made no answer, upon which the devil began to swear and to talk obscenely. This betrayed the lurking fiend. But the holy blacksmith was prepared for all casualties; so putting up a secret ejaculation, he pulled his tongs, which were red hot, out of the fire, and seizing the devil by the nose, squeezed the Satanic organ of smell with a degree of energy which caused his infernal majesty to bellow and scold at such a rate that he awakened and terrified all the people for many miles around. Thus far the legend.

However ridiculous these fictions may seem, they served, in those times of ignorance, to procure Dunstan a reputation which has been confirmed by the authority of several succeeding historians. It appears that this extraordinary person was called to court in 941 by King Edmund, who bestowed upon him the rich abbey of Glastonbury, which for his sake he honoured with many peculiar privileges. Dunstan enjoyed in a very high degree the favour of this prince during his short reign of six years; but he stood much higher in the grace of his brother and successor King Edred, to whom he was confessor, chief confidant, and prime minister. During this period of court favour he employed all his influence in promoting the interest of the monks of the Benedictine order, to which he belonged, and of which he was a most active and zealous patron. Having the treasures of these two princes, especially of the last, at his command, he lavished them away in building and endowing monasteries for these monks, because almost all the old monasteries were in the possession of secular canons; and not contented with this, he persuaded Edred to bestow, by his last will, such immense treasures on the churches and monasteries, that the crown was stripped of its most valuable possessions, and left in a state of indigence. This conduct of Dunstan, whilst he was in power, rendered him very odious to Edwy, who succeeded his uncle Edred in 955; and his rude behaviour to the king himself, and his beloved queen Elgiva, raised the resentment of that prince to such a height that he deprived Dunstan of all his preferments, and drove him into exile. The banishment of Dunstan, the great patron, or, as Malmsbury calls him, the prince of monks, was a severe blow to that order, who were in consequence expelled from several monasteries. But their sufferings were not of long continuance; for Edgar, the younger brother of Edwy, having raised a successful rebellion against his brother, and usurped all his dominions on the north side of the Thames, recalled Dunstan, and in 957 conferred on him the bishopric of Worcester. From this moment he was the chief confidant and prime minister of King Edgar, who in 959 became sole monarch of England, by the death of his elder brother Edwy. In the following year Dunstan was raised to the archiepiscopal see of Canterbury; and being thus possessed of the primacy and assured of the royal support and assistance, he prepared to execute the grand design which he had long meditated, of compelling the secular canons to put away their wives and become monks, or, in case of resistance on their part, of driving them out, and introducing Benedictine monks in their stead. With this view he procured the promotion of Oswald to the see of Worcester, and of Ethelwald to that of Winchester, two prelates who were monks themselves, and animated with the most ardent zeal for the advancement of their order; and these three great champions of monachism found means, by their arts and intrigues, in the course of a few years, to fill no fewer than 48 monasteries with Benedictines. But on the death of Edgar in 957 they received a check. The sufferings of the persecuted canons had excited much compassion; and many of the nobility, who had been overawed by the power and zeal of the late king, now espoused their cause and promoted their restoration. Elferc duke of Mercia drove the monks by force out of all the monasteries in that extensive province, and brought back the canons, with their wives and children; whilst Elfwin duke of East Anglia, and Brithnot duke of Essex, raised troops to protect the monks in these countries. In order to allay these commotions, several councils were summoned, and Dunstan was so hard pushed by the secular canons and their friends, that he was obliged to practise some of his holy stratagems; but finally, by dint of miracles, he overcame all opposition.

St Dunstan died in 988, in the sixty-fourth year of his age; having held the bishopric of London, together with the archbishopric of Canterbury, about 27 years. As this prelate was the great restorer and promoter of the monastic institutions, the grateful monks, who were almost the only historians of those dark ages, have loaded him with the most extravagant praises, and represented him as the

greatest wonder-worker and highest favourite of Heaven that ever lived.

DUNSTER, a market-town of Somersetshire, situated in a beautiful vale, at the foot of the Quantoch Hills, about a mile from the Bristol Channel. It consists chiefly of two streets, one running north and south, and the other branching off towards the west. The principal buildings are the castle and the parish church, the latter a spacious and handsome edifice with a tower. Pop. of parish (1851) 1184.

DUNUM, a Celtic term denoting a hill or eminence, which frequently enters into the composition of the ancient names of towns, to indicate their elevated situation as places of strength or citadels. See DUN.

DUNWICH, in Suffolk, 26 miles N.E. of Ipswich, the Domoc or Dunmoc of the Saxons, and the capital of East Anglia, was formerly an important seaport-town, and the seat of an extensive trade. Its harbour and the greater part of the town have been destroyed by encroachments of the sea, and it is now only a poor fishing village with 294 inhabitants.

DUODECIMO (abbreviated 12mo) is applied to a book of which each sheet is folded into 12 leaves.

DUODENUM, the commencement of the intestinal canal; the first of the small intestines. See ANATOMY.

DUPIN, LOUIS ELLIES, doctor of the Sorbonne, and professor of philosophy in the Royal College, one of the greatest ecclesiastical critics of his time, was born at Paris in 1657. When he published the first volume of his *Bibliothèque Universelle des Auteurs Ecclésiastiques*, in 1686, the liberty with which he discussed the merits of some ecclesiastical writers gave so much offence that, at the instigation of Bossuet, M. de Harlay, archbishop of Paris, compelled Dupin to make a retractation, and to suppress the work. He was, however, afterwards permitted to continue it, by altering the title from *Bibliothèque Universelle* to *Bibliothèque Nouvelle*. This great undertaking was ultimately brought to a close in 47 vols., and several translations of it appeared almost immediately. Dupin was a man of prodigious reading, and had an easy, happy way of writing, with a singular talent for analysis; a quality which renders his *Bibliothèque* very valuable. He was for some time editor of the *Journal des Sçavans*. He was banished for a time from his chair in the Royal College for having subscribed the famous *Cas de Conscience*, and thus identified himself in some measure with the Jansenists. He afterwards, however, withdrew his subscription, and was restored to office. He corresponded with Archbishop Wake in regard to the proposed union of the English and French Churches, and is said to have been consulted by the czar of Russia in regard to a similar union of the French with the Greek Church. Dupin died in 1719.

DUPLE (Lat. *duplus*), double. Duple ratio is that of 2 to 1. Thus the ratio of 8 to 4 is duple, or as 2 to 1.

Sub-duple ratio is the reverse, or as 1 to 2, 4 to 8, 6 to 12, &c.

DUPLICATE, a copy or transcript of anything; as of a deed, letter, bill of exchange, &c.

DUPLICATION, the act of doubling; the multiplication of a number by 2. Also a folding; a fold.

DUPLICATION OF THE CUBE, a celebrated problem of the ancient geometry, by which it was required to construct a cube whose solid contents should be double the solid contents of a given cube. See MATHEMATICS.

DUPLICATURE, a doubling; a fold. In *Anatomy*, the folds of a membrane or vessel.

DUPONDIUS, in *Antiquity*, a weight of two pounds, or money of the value of two asses. See AS; LIBRA; POUND.

DUPPA, BRIAN, a learned English bishop, was born in 1589, at Lewisham, Kent, where his father was then vicar. In 1634 he was constituted chancellor of the church at Sarum, and soon afterwards made chaplain to Charles I. He was appointed tutor to Charles prince of Wales and his brother James duke of York in 1638; and in the same year nominated to the bishopric of Chichester. In 1641 he was translated to the see of Salisbury, but received no benefit from this preferment, owing to the suppression of episcopacy. Charles I. held him in high esteem, and is said to have derived assistance from him in composing the *Eikon Basilike*. After the Restoration he was made bishop of Winchester, and lord high almoner. Duppa died at Richmond in 1662, aged seventy-three, and was buried in Westminster Abbey. He published a few sermons and tracts on practical religion.

DUPUIS, CHARLES FRANÇOIS, an eminent French writer, and member of the Institute, was born of poor parents at Trye-Château, between Gisors and Chaumont, Oct. 26, 1742. His father, who was a teacher, instructed him in mathematics and land-surveying. The Duke de la Rochefoucault, who accidently became acquainted with young Dupuis, took him under his protection, and gave him a bursary in the College of Harcourt.

Dupuis made such rapid progress in his studies, that at the age of twenty-four he was appointed professor of rhetoric at the college of Lisieux. In his hours of leisure he applied himself to the study of the law, and in 1770 was admitted an advocate before parliament. He was charged by the rector of the university with the task of delivering the customary discourse at the distribution of prizes; and he was also employed in the name of the university to compose the funeral oration of the Empress Maria Theresa of Austria. These two works having been printed, they were admired on account of their elegant Latinity, and laid the foundation of the author's fame as a writer.

The mathematics having been the object of his early studies, he now devoted his more serious attention to that science; and for some years he attended the astronomical lectures of Lalande, with whom he formed an intimate friendship. In 1778 he constructed a telegraph on the principle suggested by Amontons; and employed it in keeping up a correspondence with his friend M. Fortin in the neighbouring village of Bagneux, until the Revolution rendered it necessary that he should destroy his machine to avoid the danger of suspicion.

Much about the same time, Dupuis formed his ingenious theory with respect to the origin of the Greek months. In the course of his investigations upon this subject, he composed a long memoir on the constellations, in which he endeavoured to account for the dissimilarity of the groups of stars in the heavens with their representations even on the most ancient planispheres, by supposing that the zodiac was, for the people who invented it, a sort of calendar at once astronomical and rural. It seemed only necessary, therefore, to discover the clime and the period in which the constellation of *Capricorn* must have arisen with the sun on the day of the summer solstice, and the vernal equinox must have occurred under *Libra*. It appeared to Dupuis that this clime was Egypt, and that the perfect correspondence between the signs and their significations had existed in that country for a period of between fifteen and sixteen thousand years before the present time; that it had existed only there; and that this harmony had been disturbed by the effect of the precession of the equinoxes. He therefore ascribed the invention of the signs of the zodiac to the people who then inhabited Upper Egypt or Ethiopia. This was the basis on which Dupuis established his mythological system, and endeavoured to explain the curious subject of fabulous history, and the whole system of the theogony and theology of the ancients.

Persuaded of the importance of his discoveries, which, however, were by no means entirely original, Dupuis published several detached parts of his system in the *Journal*

des Sçavans for the months of June, October, and December 1777, and of February 1781. These he afterwards collected and published, first in Lalande's *Astronomy*, and then in a separate volume in 4to, 1781, under the title of *Mémoire sur l'Origine des Constellations, et sur l'Explication de la Fable par l'Astronomie.* The theory propounded in this memoir was refuted by M. Bailly, in the fifth volume of his *History of Astronomy;* but, at the same time, with a just acknowledgment of the erudition and ingenuity exhibited by the author.

Condorcet proposed Dupuis to Frederick the Great of Prussia as a fit person to succeed Thiébault in the professorship of literature at Berlin; and Dupuis had accepted the invitation, when the death of the king put an end to the engagement. The chair of humanity in the college of France having at the same time become vacant by the death of M. Bejot, it was conferred on Dupuis; and in 1788 he became a member of the Academy of Inscriptions. He now resigned his professorship at Lisieux, and was appointed by the administrators of the department of Paris one of the four commissioners of public instruction.

At the commencement of the revolutionary troubles Dupuis sought an asylum at Evreux; and having been chosen a member of the national convention by the department of the Seine-et-Oise, he distinguished himself by the moderation of his speeches and public conduct. In the third year of the republic he was elected secretary to the assembly, and in the fourth he was chosen a member of the council of Five Hundred. After the memorable 18th *Brumaire* he was elected by the department of Seine-et-Oise a member of the legislative body, of which he became the president. He was afterwards proposed as a candidate for the senate; and here terminated his political career.

In 1794 he published his large work, entitled *Origine de tous les Cultes, ou la Religion Universelle*, 3 vols. 4to, with an atlas, or 12 vols. 12mo. This work made a considerable sensation at first; it gave umbrage to many, was attacked and defended with warmth, at length ceased to be read, and fell into utter neglect. In 1798 he published an abridgment of this work in one volume 8vo, which met with no better success. Another abridgment of the same work, executed upon a much more methodical plan, was published by M. de Tracy. The other works of Dupuis consist of two memoirs on the *Pelasgi*, inserted in the *Memoirs of the Institute;* a memoir *On the Zodiac of Tentyra*, published in the *Revue Philosophique* for May 1806; and a *Mémoire Explicatif du Zodiaque Chronologique et Mythologique* published the same year, in one volume 4to. It was from the perusal of the poem of *Nonnus*, which he once thought of translating into French, and of which a fragment was printed in the *Nouvel Almanach des Muses* for 1805, that Dupuis caught the first idea of his astronomical system.

Dupuis died at Is-sur-Til, Sept. 29, 1809, leaving behind him several manuscripts on subjects connected with the works which he had published during his life. He was a member of the Legion of Honour; and his character was that of an honest man and a paradoxical writer. He was sprung from poor parents, and never acquired any fortune. M. Dacier, secretary to the third class of the Institute, delivered his *Eloge;* and an historical account of his life and writings was published by his widow. (See also *Biographie Universelle.*)

DUPUYTREN, GUILLAUME, BARON, one of the most distinguished of French surgeons, was born October 6, 1777, at Pierre Buffière, a small town of Limousin. He was sprung from poor parents, and was furnished with the means of receiving an ordinary education at the Collége de la Marche, by some charitable persons to whom he had been introduced. At the Ecole de Médecine, he began the study of medicine with invincible ardour, and was appointed prosector of the faculty when only 18 years of age. When only 26 he succeeded Peletan as head surgeon at the Hôtel-Dieu; and he was appointed professor of surgery at the age of 33. At the same time he became inspector of the university, a chevalier and afterwards an officer in the Legion of Honour, chevalier of St Michel, baron, member of the Institute, and first surgeon to the king.

Dupuytren's energy and industry were alike remarkable. He visited the Hôtel Dieu morning and evening, performing at each time several operations, lectured to vast throngs of students, gave advice to his out-door patients, and fulfilled the duties consequent upon one of the largest practices of modern times. By his indefatigable diligence and activity, he amassed a fortune of L.300,000, the bulk of which he bequeathed to his daughter, but deducting considerable sums for the endowment of the anatomical chair in the Ecole de Médecine, and the establishment of a benevolent institution for distressed medical men.

Dupuytren's writings are by no means numerous. The most important of them is his *Treatise on Artificial Anus*, in which the principles laid down by John Hunter are happily applied. In his operations he was remarkable for the skill and dexterity with which he overcame the numerous difficulties incidental to so extensive a practice as he enjoyed. Instead of attempting to introduce new methods of procedure, he commonly limited himself to modifying and adapting to his particular exigencies the established laws of surgery. In private life, Dupuytren was cold and reserved; his brow, furrowed with wrinkles, betrayed the weight of cares with which he was burdened; and it was seldom that a smile, except one of irony or disdain, played about his lips. His unsocial coldness was further heightened by his constant struggle against a consumptive tendency, which ultimately carried him off, 8th February 1835.

After death Dupuytren's head was opened, and his brain taken out and weighed. Its weight was found to be exactly the same with that of Dr Abercrombie, viz. 64 ounces.

DURA MATER, the outer enveloping membrane of the brain, overlying the *pia mater*, and adhering to the inner surface of the cranium. See ANATOMY.

DURANCE (the ancient *Druentia*), a river in the south of France, rising in Mont Genèvre, in the department of Hautes-Alpes, and falling into the Rhone 4 miles below Avignon, after a course of about 160 miles. It flows at first southward, through the departments of the Alps; and then, turning westward, forms the boundary between the departments of Vaucluse and Bouches-du-Rhône. Its chief affluents are the Buech and the Verdon. The current of the river is rapid, and large quantities of timber are floated down from the mountains, but no part of its course is navigable.

DURANDUS, GULIELMUS (1237–1296), one of the most learned lawyers of the thirteenth century, was born at Puymoisson, in Provence. He was a pupil of Henry of Susa, and taught canon law at Modena. He was afterwards made chaplain and auditor of the sacred palace, legate of Gregory X. at the council of Lyons, and in 1286 was raised to the see of Mende. His works are, 1. *Speculum Juris*, Rome, 1474, folio, whence he derived the name of *Speculator;* 2. *Rationale Divinorum Officiorum*, Mentz, 1459, folio, scarce; 3. *Repertorium Juris*, Venice, 1496, folio.

DURANGO, a province of Mexico. See MEXICO.

DURANGO, or GUADIANA, a city of Mexico, capital of the province of the same name, is situated in a wide plain 6847 feet above the level of the sea. Lat. 24. 25. N., Long. 105. 55. W. It was originally founded in 1559 by the viceroy Velasco, as a military post for the control of the Chichimecas. Its present importance is owing to the mineral wealth of the vicinity. As late as 1783 it contained not more than 8000 inhabitants, but its present population is estimated at from 30,000 to 40,000. The town is regularly built with many fine streets, and an elegant *plaza* or square. Among its public buildings are the cathedral, theatre, and

mint. Its chief manufactures are woollen and cotton stuffs, glass, leather, and tobacco. In the vicinity are rich iron mines.

DURAZZO (the ancient *Epidamnus* and *Dyrrachium*), a seaport-town of Albania, European Turkey, in Lat. 41. 17. N., Long. 19. 27. E. It stands on the S. side of a projecting tongue of land, and has a safe harbour for vessels of small size, but larger vessels must anchor about a mile from the town. It has an active import trade in British goods by way of Triest, and an export trade in tobacco and corn to Italy. Pop. probably about 6000. See EPIDAMNUS.

DUREN (the ancient *Marcodurum*), a town of Rhenish Prussia, capital of a cognominal circle on the Roër, here crossed by a stone bridge, and on the Cologne and Aix-la-Chapelle railway, 18 miles E. by N. of the latter city. Pop. (1849) 8054. It has several Roman Catholic and Protestant churches, a Roman Catholic gymnasium, and three nunneries. The manufactures are extensive, and include cotton and woollen stuffs and cassimeres, cutlery, nails, wire, and other hardware goods; soap, leather, paper, and brandy. Charlemagne held two diets here in 775 and 779, when on his way to attack the Saxons. It afterwards became an imperial city, and was taken by assault and burned by Charles V. in 1543. In 1794 it fell into the hands of the French, and was made the capital of the department of Roër, but was ceded to Prussia in 1814.

DURER, ALBRECHT, one of the best engravers and painters of his age, was descended of a Hungarian family, and born at Nuremberg in May 1471. He was the son of a goldsmith, but early relinquished his father's trade for the study of art under Michael Wohlgemuth. After obtaining his mastership, Dürer travelled in Holland and Italy, where he gained the friendship of Raphael. He was appointed painter to Maximilian I. and Charles V. He was a man of letters and a philosopher, and an intimate friend of Erasmus, who revised some of the pieces which he published. He was a man of business also, and for many years the leading magistrate of Nuremberg. Though not the inventor, he was one of the first improvers of the art of engraving; and he also wrought in wood, on which he engraved the life and passion of Christ in thirty-six pieces, which were highly esteemed. In many of those prints which he executed on copper, the engraving is exceedingly elegant. His Hell scene particularly, engraved in 1513, is as highly finished and as happily executed a print as ever was engraved. In his wood prints too, it is surprising to find so much meaning in so early a master; the heads being well marked, and every part admirably executed. His composition is often pleasing, and his drawing generally good; but he knew very little of the management of lights, and still less of grace. Yet his ideas are purer and more elegant than might have been expected from the awkward archetypes which his country and education afforded. Albert Dürer was certainly a man of great natural genius; and, as Vasari remarks, he would have been an extraordinary artist if he had had an Italian instead of a German education. His prints are very numerous, and were much admired and eagerly bought up in his own lifetime. He was rich, and chose rather to practise his art as an amusement than as a business. He died at Nuremberg, April 6, 1528; and the well-known discomforts of his marriage have induced his countrymen to attribute his death principally to domestic misfortune. He was interred in St John's Church, where a public monument was erected to his memory. He is sometimes regarded as the inventor of woodcuts and etching. Besides his artistic productions, Dürer wrote several books in German, which were translated into Latin by other persons, and published after his death. Among these we may mention, 1. *De Symmetria Partium in rectis formis Humanorum Corporum*, Nuremberg, 1532, Paris, 1557, fol.; 2. *Institutiones Geometricæ*, Paris, 1532; 3. *De Urbibus, Arcibus, Castellisque condendis et muniendis*, Paris, 1531; 4. *De Varietate Figurarum, et flexuris Partium, et gestibus Imaginum*, Nuremberg, 1534. (See *Reliquien von Albrecht Dürer, seinen Verehrern geweiht, Taschenbuch für Deutschland's Kuntsfreunde, zu Albrecht Dürer's dritter Secular-feier*, Nürnberg, 1828.)

DURESSE (*duritas, hardness*), is used in law to denote such constraint, either by illegal imprisonment, or by threats occasioning a reasonable fear for personal safety, as renders invalid a legal act (as the execution of a deed, &c.) performed by the person suffering such constraint. Duresse by threats (*per minas*) is interpreted to mean such as occasion fear of life or limb.

D'URFEY, THOMAS, more generally known by the familiar name of Tom d'Urfey, an English satirist and song-writer, was descended from a family of French Protestant refugees, and was born at Exeter. He was originally bred to the law, which he forsook for the more congenial employment of writing plays and songs. His humour both in writing and singing the latter procured him access to the highest circles, and made him a favourite even at court. A writer in the Guardian (No. 67) relates that he remembered more than once to have seen Charles II. leaning on Tom d'Urfey's shoulder and humming over a song with him. His dramatic pieces were equally well received, but are too licentious to be reproduced upon the stage. D'Urfey, by imprudence and extravagance, became poor as he grew old; and having prevailed on the managers of the playhouse to act his comedy of the *Plotting Sisters* for his benefit, Addison wrote the above-mentioned paper in the Guardian, with another (No. 82) giving a humorous account of his eccentricities, in order to procure him a full house. He died at an advanced age, in 1723. His collected works, under the title of *Pills to Purge Melancholy*, command a high price.

DURHAM, COUNTY PALATINE OF, one of the shires of England. Before the arrival of the Romans it was included in the British principality of the Brigantes; and after their arrival it made part of the province of *Maxima Cæsariensis*. During the heptarchy it formed part of the kingdom of Northumberland, the fifth established, which began in 547, and ended in 827, having been governed by thirty-one kings. It was not mentioned by Alfred in his division of counties, being at that time considered as a part of Yorkshire. At present it is included in the northern circuit, in the province of York, and is a diocese and principality under the government of its own bishop, being a county palatine, the second in rank, and the richest in England. It is bounded on the N. by Northumberland, on the S. by Yorkshire, on the E. by the North Sea, and on the W. by Cumberland. It extends over 973 square miles, and contains one city of the same name, fourteen market-towns, and above 330 villages and hamlets. It is divided into four wards. Until the passing of the Reform act, it returned two members to the House of Commons for the county and two for the city. The county has been formed by that law into two divisions, for the purpose of parliamentary elections; each of which returns two members. The northern division comprehends the wards of Chester and Easington; and the polling places are Durham, Sunderland, Lancheton, Wickham, Chester-le-Street, and South Shields. The southern division comprehends the wards of Darlington and Stockton; and the polling places are these two towns, and Bishop-Auckland, Stanhope, Middleton-in-Teesdale, Barnard Castle, and Sedgefield. Durham city and Sunderland return two members each. The following places within the county have by the same law obtained the privilege of electing one member each, viz. Gateshead and South Shields; the whole number returned amounting to ten. The population in 1851 was 390,997—an increase of 160 per cent. in 50 years. The number of inhabitants to a square mile was 399; to a house 6. The total number of houses was

Durham. 68,341; 64,977 being inhabited, 2794 uninhabited, and 570 in the course of erection.

This is one of the county palatines remaining in England, and it is called *palatine* (*a palatio*) because the owners thereof had, in this county, the authority to use the royal prerogative, as fully as the king had in his palace. These privileges were granted to this county probably on account of its bordering upon the inimical kingdom of Scotland, in order that the inhabitants, having justice administered at home, might not be obliged to go out of their county, and leave it open to an enemy's incursions; and that the owners might be the more watchful in its defence. There is a court of chancery in this county, and the bishop is at the head of the administration of justice.

The western angle of the county of Durham is hilly and mountainous, with black, naked, and barren regions, crossed by a ridge of high hills, from which issue numerous streams flowing to the sea. There are some beautiful and fertile valleys in the eastern and central parts, pleasantly varied with hill and dale, and alternately appropriated to corn and pasture. About 1200 to 2000 acres, principally in the western part of the county, are waste, but rich in minerals.

In the southern districts many acres have been inclosed and cultivated within the last few years. The common fields are now but few; for the land belonging to the townships has been inclosed for above a century. There is a great portion of wet ground still remaining, although draining is carried on to a great extent.

Near the river Tees, and in some spots bordering on the other rivers, the soil is loam or a rich clay. At a farther distance from these rivers the soil is of an inferior quality, and marshy, with patches of gravel interspersed. The hills between the sea and an imaginary line from Barnard Castle on the Tees to Alansford on the Derwent, are covered with a dry loam, the fertility of which varies with its depth. From this line westward the summits as well as the sides of the hills are moorish wastes.

The woodlands of Durham are not of very considerable extent, trees being chiefly confined to the parks and seats of the nobility and gentry; but many plantations have been made of late years. The banks of the rivers and brooks, however, particularly in the vicinity of Durham, are fringed with wood of long growth and much value.

The port of Stockton-upon-Tees is well situated for commerce. Hartlepool, situated on a promontory, nearly encompassed by the German Ocean, which on the south side of the town forms a capacious bay, is advantageously placed for the reception of vessels, and communication with the Continent; and South Shields sends out many ships.

Mines. The mineralogical substances found in Durham are numerous and valuable. The coal mines are some of the most extensive and productive in the kingdom, and the quantity of this important article is so great as to exceed all calculation. At Sunderland the coal trade furnishes employment for 520 vessels, independently of the *keels* which convey the coal from the staiths to the ships, which are 492 in number. This coal is chiefly conveyed to the metropolis, though great quantities are sent to the different ports of the Baltic, and also of late years to France and Holland. The whole quantity annually exported from Sunderland alone amounts to about 315,000 Newcastle chaldrons, each chaldron being equal to 53 cwt. The number of persons dependent on this trade is very great. The seams or strata now worked are five in number, extending horizontally for many miles, and are from twenty to one hundred fathoms beneath the surface; while each stratum is from three to eight feet thick. Below these are several other seams of coal; and many parts of the county, besides those where the pits are now open, abound with this substance.

The principal lead mines of Durham are in the districts of Teesdale and Weardale. Those of the former place have not been very productive, but the produce of the latter is of considerable value. The general method of working them is similar to that pursued in other mining counties. The ore of Weardale is melted by the blast-hearth; but in Teesdale air-furnaces have been introduced with much success.

Ironstone is found in the neighbourhood of Swalwell and Winlaton, where there are extensive iron works.

Some excellent quarries of slate for buildings have been opened in different parts of the county. A beautiful black spotted limestone is dug up near Walsingham, and made into hearths, chimney-pieces, and other ornaments. This neighbourhood abounds also with fine millstones. The Newcastle grindstones are procured at Gateshead Fell; and firestone of high estimation, for building ovens, furnaces, and the like, is obtained in various parts of Durham, and exported in considerable quantity.

Several extensive works for manufacturing salt from sea-water have long been established in the neighbourhood of South Shields; but owing to the discovery of a very singular salt spring at Birtley in this county, that process is not now so much attended to. This water rises at the depth of seventy fathoms, in an engine pit constructed for drawing water out of coal mines. It has for many years produced 20,000 gallons per day, four times more strongly impregnated with salt than any sea-water. In consequence of the discovery of this spring, a large and extensive manufactory of salt has been established near the spot, the quality of which is excellent. At Butterby, near Durham, is another salt spring, which issues from a rock in the river Wear, but is only visible when the water is low. It contains more of the sulphate of magnesia or Epsom salt, than the spring at Birtley. Within a few yards of the Watergate, on the south side of the town of Hartlepool, is a chalybeate spring, covered every tide by the sea. It is impregnated slightly with sulphur, which evaporates very quickly, leaving a sediment with salt of tartar. A gallon will yield 120 grains of sediment, two parts of which are nitrous, and the rest limestone.

No county in England presents a closer net-work of railways than Durham. The York, Newcastle, and Berwick trunk line enters a few miles south of Darlington, and continues due north until at Gateshead it crosses the Tyne and enters Northumberland. From this main line a great many lines diverge to the ports and mineral fields. There are not less than 160 miles of rail for mineral produce between the mines and ports.

Improvements in agriculture have been pursued with considerable spirit and success in the environs of Darlington, chiefly through the patronage of a society of county gentlemen, who hold their meetings in the town, and bestow premiums upon merit. On some spots of gravelly soil, turnips and barley are grown in almost perpetual succession, a crop of clover being sometimes interposed. The produce of wheat on good land is from twenty to thirty bushels per acre; the produce of barley is from thirty to forty; of oats, from twenty to forty. The manures are chiefly lime and the produce of the fold-yard; and though abundance of sea-weed might be collected on the coast, the farmers make but little use of it. The farms are of a middling size, few of them exceeding 200 acres. The largest portion of each farm is appropriated to tillage, but towards the western extremity of the county the whole is applied to pasture. The leases seldom exceed six years, and are too frequently rendered of little value by injudicious restrictions. The leases held of the see of Durham are generally for life, or for twenty-one years, renewable every seven years on payment of a fine. The farm-houses are well situated and commodious; and improvements in farming and farming machinery become more and more common.

The cattle of Durham are at present in great repute; as, in point of form, weight, produce of milk, and quickness of fattening, there are none better. The individual known as "the Durham Ox," when slaughtered, weighed, including tallow and hide, 197 stone, 2 lbs. The cows yield from from 25 to 30 quarts of milk daily. The sheep also, particularly the Tees-Water breed, stand high in estimation It is the largest breed in the island; the legs being longer, finer boned, and supporting a thicker and more firm and heavy carcass than the Lincolnshire. They are also much wider on the backs and sides, and afford a fatter and finer-grained mutton. The weight per quarter, in two-years-old wethers, is from twenty-five to thirty-five ponnds, and in particular instances fifty-five pounds or more. The wool is shorter and lighter than some other English breeds. The Weardale sheep are small, but the meat is finely flavoured. When fat, the quarters seldom weigh more than fourteen or eighteen pounds each. The stock of sheep is about 230,000, yielding 7000 packs of wool.

Durham, taking its dimensions into consideration, is inferior to no county in Great Britain for its numerous manufactures. It has cast-metal founderies, iron manufactories, potteries, glass-houses, copperas works, coal-tar and salt-works, quarries of marble, &c.; besides linen and woollen manufactories.

At the distance of about three miles from Darlington, at Oxenhall, are cavities in the earth, denominated Hell Kettles, to the origin of which are attached many fabulous conjectures. The diameter of the largest is not less than 114 feet, and that of the least 75. About five miles from Hartlepool is one of the most singular and romantic clusters of rocks in the north of England, called Black Halls, formed by the force and constant action of the waves, which have separated enormous masses from the coast, washing some entirely away, but leaving others standing, like the vast towers of a cathedral. In some places the rock is perforated so as to resemble a fine pointed archway.

Near the north wall of the churchyard at Ryton is a large barrow, about 20 feet in perpendicular height, now planted with trees. A similar one, near Bradley Hall, in the same parish, inspected some years ago, was found to contain a square cavity, formed by stones placed edgewise, in which a human body had been interred. Between one and two miles north of Brancepeth is Brandon Hill, a lofty eminence, on the summit of which is a remarkable tumulus, of an oblong form, 120 paces in circumference at the base, and about 24 feet in perpendicular height. One mile north of Eggleston is an ancient structure called the Standing Stones. This originally consisted of a cairn in the centre, surrounded by a trench, and that again encompassed by a circular arrangement of rough stones, many of which have been removed and broken, to repair the roads. Near a brook, at a small distance, is a large barrow, crossed from east to west by a row of stones.

On Fullwell Hill, a gigantic skeleton and two Roman coins were discovered some years ago, together with a small urn of unbaked clay. Several copper coins have been found at the village of Whitburn. Some coins of the Emperor Hadrian were found while widening the road near Gateshead, which is supposed to have been a Roman station.

South Shields was the *ad finem* of Richard of Cirencester's itinerary, as appears from the Roman altars, coins, and other relics found there. Evchester, a small irregular village, is supposed to be the *Vindomara* of Antoninus; many Roman inscriptions, and an urn of uncommon form, nearly a yard high and seven inches wide, with a small cup in the centre, having been found there. Chester-le-Street has been supposed to be the *Condercum* of the Romans, situated on the military way leading to Newcastle. Glanibanta, near the village of Lanchester, is another Roman station, which has hitherto been left untouched in the course of improvements, and is one of the most perfect in the kingdom. It occupies a fine eminence, and is of an oblong figure, being 174 paces from north to south, and 160 from east to west, within the vallum. In some parts the wall still remains perfect; the outside is perpendicular, twelve feet in height, and built of ashler work in regular courses, each stone being about nine inches thick and twelve long. The site of the prætorium is clearly distinguishable. Binchester, the seat and manor of the Wren family, is the site of the Roman station called *Vinovium* by Antoninus. Its figure and extent seem nearly similar to those of the station just mentioned; but the walls have been destroyed, and the area inclosed and cultivated. A military way, it is supposed, issued from it, leading towards Chester-le-Street. Innumerable fragments of Roman remains have been discovered here.

The most ancient part of Durham Castle is the keep, now a mere shell; the magnificent hall is fast going to decay. Hilton Castle, an ancient baronial residence of the Hyltons, is situated in a pleasant vale on the north side of the Wear, about three miles from Wearmouth: its present form is that of an oblong; the interior consists of five stories; the rooms are small, and exhibit every symptom of neglect and decay. Ravensworth Castle, the seat of Lord Ravensworth, occupies part of the site of an ancient castle, which seems to have formed a quadrangle, having a square tower at each angle, connected by a curtain wall. Two of the towers are built up in the offices, the others are partly in ruins. Lumley Castle, about a mile to the east of Chester-le-Street, is one of the seats of the Earl of Scarborough. It forms a quadrangle, with an area in the centre; at each angle are projecting turrets of an octangular form; it is a grand model of the taste of its age. Brancepeth Castle, an irregular but stately pile, was erected about Stephen's reign, by the family of Bulmers. The original building has had many modern improvements effected on it by the present proprietor. The castle of Bishop-Auckland stands on the north angle of the town, and, together with its courts and offices, covers about five acres of ground. Raby Castle, the magnificent seat of the Duke of Cleveland, owes its splendour to the Earl of Westmoreland, who enlarged a more ancient castle which stood here prior to the year 1379. The present mansion of Streatham Castle was erected on the foundation of the old castle at the beginning of the last century, and several of the apartments are retained in it. Barnard Castle is situated on the southern acclivity of an eminence, rising with a steep ascent from the river Tees; its ruins cover an extensive plot of ground.

Kepier Hospital, near Durham, was founded in 1112; but the only part of the monastic buildings now standing is the gateway, a strong and not unhandsome piece of masonry with pointed arches. The ruins of a monastery for gray friars may be seen at Hartlepool. Several remains of monastic buildings occur near the church at Monk-Wearmouth. The monastery of Jarrow may still be traced in its ruins on the summit of an elevated ridge near the church. On the east side of the main street of Gateshead are the ruins of St Edmond's Monastery, which appears from Bede to have been established before the year 653. Finchall Priory was beautifully situated in a vale on the banks of the Wear; the ruins cover an extensive plot of ground, but are so much dilapidated that the original appropriation of their respective parts can be traced only with great difficulty. The remains of a chapel at Bear Park are most perfect, and display some neat ornamental architecture. There are at Walsingham the ruins of a considerable building, inclosed with a deep moat, supposed by some to have been a part of a monastery.

The ecclesiastical buildings now remaining, and most worthy of notice, are, the Cathedral of Durham, begun in 1093, in the Saxon and Norman style: Sedgefield Church,

in the Saxon style; Bishop-Wearmouth Church, supposed to have been founded very soon after the restitution made by Athelstan; and the parish church of Brancepeth, an ancient structure of the conventual form, but apparently of different ages.

Annual value of real property assessed L.1,679,938. Places of worship belonging to Church of England 169, sittings 68,958; other denominations 452 places of worship, sittings 112,874: day schools 837, scholars 49,231; Sunday schools 490, scholars 47,771.

Durham, the capital of the above county, is a city of great antiquity. About the end of the tenth century the monks of Lindisfarne rested here with the remains of St Cuthbert; and soon afterwards a church was built by Bishop Aldun, and dedicated to that saint, whose remains were enshrined in it. Durham suffered severely from the cruelties of William the Conqueror, who repeatedly laid waste the surrounding country with fire and sword. In 1072 a strong castle was built here; and Walcham, a Norman, was appointed to the bishopric, and assumed the title of Count Palatine. In 1093 the old church built by Aldun was pulled down, and the present magnificent edifice commenced by King Malcolm, Carilepho the bishop, and Targot the prior. Durham figured conspicuously in all the great transactions that have agitated the north. It frequently suffered from the invasions of the Scots; and was often the headquarters of Edward III. and other monarchs and commanders in their excursions against Scotland. Durham is governed by a mayor, 6 aldermen, and 18 councillors, and returns two members to parliament. Pop. (1851) 13,188. The city is irregularly built on a rocky eminence, and is nearly surrounded by the river Wear. The cathedral and castle occupy the highest part of the eminence, and are fully 80 feet above the bed of the river. The cathedral was founded in 1093, and is one of the noblest edifices in the kingdom. The successive additions which have been made to it afford a striking illustration of the gradual changes in the English style down to the beginning of the fifteenth century. This remarkable edifice has been admirably delineated in Billings' *Architecture of Durham Cathedral.* It is 507 feet in length, by 200 in extreme breadth, with a central tower 214 feet in height, and two smaller ones 138 feet high at the west end. The Galilee or western chapel was built by Bishop Pudsey between 1153 and 1195, and contains the remains of the Venerable Bede. In the chapel of the Nine Altars are the remains of St Cuthbert, brought to light in 1827. The cathedral library contains a number of curious and interesting works, MSS., and relics. The castle of Durham, which stands opposite the cathedral, was erected by William the Conqueror, and till recently was the residence of the bishops of the Palatinate. It is now appropriated to the uses of the university, with the exception of a suite of rooms reserved for the use of the bishop when he visits the city. A university was founded here by Cromwell in 1657, but on the Restoration it was dissolved. The present university was opened in 1833; an account of it will be found under the head Universities. The see of Durham was long the richest bishopric in England. At an average of the three years ending 1831, it yielded a nett revenue of L.19,066 a-year. The total revenue of the dean and chapter during the seven years ending 1834 amounted to L.36,937 a-year. On the demise of the incumbent in 1836, at the recommendation of the ecclesiastical commissioners the income of the bishop was fixed at L.8000 per annum—the surplus revenues of the see being reserved to form a fund for augmenting the incomes of the poorer bishops. Besides the cathedral, Durham has six parish churches, and places of worship for Independents, Methodists, Quakers, and Roman Catholics. The grammar-school connected with the cathedral has four exhibitions of L.25 each for the sons of clergymen, and of L.50 each at either of the English universities, besides several scholarships at Peterhouse, Cambridge. There are also a diocesan training school, a blue coat, national, infant, charity, and other schools. Durham likewise possesses a mechanics' institute, savings-bank, subscription library, news-room, assembly rooms, theatre, infirmary, alms-houses, and various charities. The banks of the river are ornamented with gardens and plantations, forming an agreeable public promenade. The district called the North and South Bailies, between the precincts of the cathedral and the river, is occupied chiefly by houses of a superior class. The principal shops are in the old town, which also contains the market-place, with a fountain in the centre. The suburbs extend on both sides of the river. On the west side is Framwellgate, with a detached suburb called Crossgate; while on the east side is the suburb Elvet, which contains the magnificent new county gaol and court-house, erected in 1809, and some of the best houses in the place. These suburbs are connected with the town by several bridges. The town-hall is a spacious and handsome edifice in the Tudor baronial style. The manufactures, consisting chiefly of hats, woollens, paper, leather, and brass and iron wares, are not important. There are extensive coal mines in the neighbourhood, as well as some saline, chalybeate, and sulphurous springs. About three-quarters of a mile from the city is the site of the Maiden Castle—a fortress ascribed to the Romans—as well as some remains of the Iknield Street. One mile to the west of Durham is Neville's Cross—erected by Ralph Lord Neville to commemorate the defeat and capture of David II. of Scotland. Market-day Saturday. The Great North of England railway connects this city with Newcastle-on-Tyne, 14 miles distant.

DURLACH, a town in the grand duchy of Baden, circle of the Middle Rhine, on the Pfinz, 3 miles east of Carlsruhe, with which it is connected by an avenue of poplars. It was formerly the residence of the margraves of Baden-Durlach, whose castle, on a contiguous height, is now in ruins, but the garden contains some Roman antiquities. Durlach has manufactures of porcelain ware and tobacco, and some trade in wine, fruit, corn, and other agricultural produce. Pop. about 5000.

DUROTRIGES, an ancient British people, established in Dorsetshire, and the west of Somersetshire. Their name is derived from the two British words, *dur*, water, and *trigo*, to dwell; which corresponds to the situation of their country, which lies along the coast. It is not certain whether they formed an independent state, or were united with their neighbours the Damnonii, since they were reduced by Vespasian at the same time as the latter, and never afterwards revolted. The peaceable disposition of the inhabitants was probably the reason why the Romans had so few towns, forts, and garrisons in this part of the island. Their chief town was Dunium, now Dorchester. Many Roman coins have been found at Dorchester. The military way, called Jeening Street, passed through it; and some vestiges of the ancient stone wall with which it was encompassed, and of the amphitheatre with which it was adorned, are still visible. The country of the Durotriges was included in the Roman province called *Flavia Cæsariensis.*

DURRESTEIN, a town of Lower Austria, capital of the circle of Upper Manhartsberg, on the left bank of the Danube, 3 miles west of Krems. Pop. about 400. Above the town are ruins of the castle in which Richard Cœur-de-Lion was imprisoned on his return from the Holy Land.

DURSLEY, a market-town in the hundred of Berkeley, county of Gloucester, and 14 miles S.S.W. of the town of that name. It is situated at the base of a steep hill, and contained (1851) 2617 inhabitants, chiefly engaged in the manufacture of cloth. Market-day Thursday.

DURY, John, a Scotch divine of the seventeenth century, who laboured with great zeal to reunite the Lutherans

with the Calvinists. He published his earliest work on this subject in 1634, and prosecuted his scheme at the Frankfort assembly, in Sweden, Denmark, Holland, Germany, and Switzerland. He was present at the London assembly of divines in 1641. His discouragements in this scheme started another still more impracticable, namely to reunite all Christians by means of a new explication of the Apocalypse, which he published at Frankfort in 1677. He afterwards retired to the country of Hesse; but the time of his death is unknown. His letter to Peter du Moulin, concerning the state of the churches of England, Scotland, and Ireland, was printed at London in 1658, under the superintendence of Du Moulin, and is extremely curious.

DUSSARA, a fortified town of Hindustan, province of Gujerat, containing about 1300 houses, which are chiefly possessed by Kurbatties; the remainder of the population being Coolees, Rajpoots, and other castes, besides a few Banyans. This place, with 25 surrounding villages, is shared among several chiefs (members of the same family), called the Maliks of Dussara, who pay an annual tribute of L.1200 to the British government. Lat. 23. 18.; Long. 71. 52.

DUSSAULX, Jean, a French writer, best known as the translator of *Juvenal*, was born at Chartres, Dec. 28, 1728. He studied first at La Flèche, and afterwards at Paris; and having obtained the situation of a commissary in the *gendarmerie*, he served under the Marshal de Richelieu, in Hanover, during the seven years' war. At the age of twenty-one he was admitted a member of the academy at Nancy; and in 1770 he published his translation of *Juvenal.* This work procured him admission into the Academy of Inscriptions; and he was also appointed ordinary secretary to the Duke of Orleans.

For some years he quietly prosecuted his literary occupations at Paris; but, upon the breaking out of the Revolution, his enthusiastic disposition led him to adopt its principles: and he took part in the debates of the legislative assembly. He spoke and voted, however, at all times for moderate measures; and, on several occasions, he was employed to calm the passions of the people during public tumults. At the memorable sitting of the convention 15th Jan. 1793, he voted that the king should be detained in custody during the war, and banished on the return of peace. It is rather remarkable, that when the committee of public safety wished to send him to the scaffold, his pardon was obtained by Marat, who represented him as an old dotard, incapable of becoming dangerous. He became president of the council of ancients in July 1796, but left it in 1798. At the sitting of 27th April, he took leave of the assembly in a speech which was ordered to be printed. He died March 16, 1799, after a long and painful illness.

Dussaulx was a man of considerable literary attainments, and amiable, upright, and disinterested in his conduct. His translation of *Juvenal* is esteemed the best version of that poet in the French language. His other works are, *Mémoires sur les Satiriques Latins; Lettres et Réflexions sur la fureur du Jeu, auxquelles on a joint une autre Lettre Morale*, Paris, 1775; *Discours sur la Passion du Jeu dans les différents Siècles; De la Passion du Jeu, depuis les temps anciens jusqu'à nos jours*, 1779, 8vo; *Vie de l'Abbé Blanchet*, prefixed to the *Apologues and Tales* of that author, Paris, 1784, 8vo; *De l'Insurrection Parisienne, et de la prise de la Bastille*, Paris, 1790; *Lettre au Citoyen Fréron*, 1796, 8vo; *Voyage à Barrège, et dans les Hautes-Pyrenées*, Paris, 1796, 2 vols. 8vo; *De mes Rapports avec Jean-Jacques Rousseau*, &c., Paris, 1798, 8vo, a curious work, which throws considerable light on the character of that celebrated man. Marie-Jeanne Lieutau, the widow of Dussaulx, published memoirs of his life, which are exceedingly interesting. See also Palissot, *Mémoires sur la Litterature;* and *Biographie Universelle.*

DÜSSELDORF, formerly capital of the duchy of Berg, but now of a cognominal government in Rhenish Prussia. It is situated at the confluence of the Düssel with the Rhine, 22 miles north from Cologne. The old town of Düsseldorf existed previously to 1288, when it became a municipal town. In 1815 it was annexed with the whole duchy to the Prussian dominions. It was at one time a considerable fortress, but after having been bombarded by the French in 1794, the fortifications were destroyed at the peace of Luneville in 1802. One of the wings of the old castle, however, has been rebuilt, and contained down to 1805 the collection of paintings which is now at Munich. It is divided into three quarters, viz. the Altstadt, Neustadt, and Carlstadt; the last deriving its name from Charles Theodore, the elector Palatine, who projected a variety of improvements in the town. The streets are generally spacious, and the suburbs are laid out in ornamental pleasure-grounds. The Hof-garten is one of the finest in Germany. In the market-place is an equestrian statue of Johann Wilhelm the elector; and a marble statue of the same individual adorns the courtyard of the old electoral palace. The principal public buildings of Düsseldorf are the governor's palace, the town-hall, courts of law, observatory, library, and churches. Of these last the oldest is St Andrew's. In it, and in the church of St Lambert, are monuments of the former princes of Düsseldorf. A native school of art has arisen since 1828, and is peculiarly vigorous in the department of historical painting. Düsseldorf derives its mercantile importance from its position on the Rhine, and serves as a port to the various manufacturing districts of the duchy. Manufactures—woollens, cottons, leather, ironware, jewellery, &c. Its principal trade is in raw produce, coals, and timber. It has constant communications by steamers on the Rhine, and also by railways, with various parts of Germany. Pop. (1851) 27,762.

DUST, or Dustee, a river of Persia, flowing from the interior through the province of Mekran, from the southern shore of which it falls into the Indian Ocean. Its course is supposed to extend, under different appellations, about 1000 miles.

DUTCH Gold, the commercial name of a coarse imitation of gold leaf, made of copper, of brass, or of bronze. It is chiefly used for ornamenting toys.

DUTENS, Louis, a French writer of some celebrity, was born at Tours, of Protestant parents, Jan. 15, 1730. In his youth he devoted himself to poetry; and in 1748 he repaired to Paris and composed a tragedy, entitled *The Return of Ulysses to Ithaca*, which he showed to the comedian Lanoue, requesting him to bring it on the stage. The latter, however, returned the piece, advising the author to retouch it. Irritated at this advice, Dutens went to Orleans, where he got his play represented with great applause; but he soon became sensible of the faults of his work, and abandoned a species of composition in which he found he was not destined to excel. He soon afterwards went to England. Before leaving France, he accidentally became acquainted with Miss Pitt, sister to the Earl of Chatham, who gave him a letter to her brother; but after a short stay in London he returned to France. Not long afterwards, he was recalled to London by one of his uncles, to accompany a young English nobleman on his travels. Soon after his arrival, the young nobleman changed his intention; but, at the same time, he procured for Dutens the situation of a tutor in a private family. The father of the pupil was a man of considerable literary and scientific attainments, who instructed Dutens in those branches of knowledge in which he was deficient. In this manner he learnt Greek and mathematics; and he at the same time applied himself to the oriental languages, and to Italian and Spanish. At the end of three years his pupil died; but one of his sisters being deaf and dumb, her education was entrusted to Dutens. His young pupil, however, having become enamoured of her instructor, Dutens deemed it a matter of delicacy and of duty to leave the house.

About this time he was appointed chaplain and secretary to the Honourable Stuart Mackenzie, the English minister

at the court of Turin, and left England in October 1758. In 1760, when Mr Mackenzie returned to England, the secretary remained at Turin as chargé d'affaires. Dutens came to England in 1762, and attached himself to the family of Lord Bute, who, before retiring from office in 1763, procured him a pension. He again went to Turin as chargé d'affaires; and during this second mission he undertook the task of collecting and publishing a complete edition of the works of Leibnitz, and wrote his work on the *Discoveries of the Ancients*. He afterwards quitted Turin, returned to Britain, and attached himself to the Duke of Northumberland, who procured him a living in the north of England. He accompanied the duke's son, Lord Algernon Percy, in his travels through France, Italy, Germany, and Holland; and while at Paris he was chosen a member of the Academy of Inscriptions. In 1776 he returned to England, and soon afterwards accompanied Mr Mackenzie and his wife on a tour to Naples. On his return he was invited by Lord Mountstuart, who had been appointed envoy extraordinary, to accompany him to Turin; and Dutens found himself for the third time chargé d'affaires at that court, during a short absence of the envoy. From Turin, which he left on account of some unpleasant circumstances, he went to Florence, and thence to Rome. He was in Paris in 1783, and returned to London the following year. The revenue he derived from his living of Elsdon, amounting to L.800 per annum, together with a considerable legacy left him by Mr Mackenzie, and estimated at L.15,000, enabled him to pass the remainder of his life in affluence. He died at London, May 23, 1812.

Dutens was the editor of the works of Leibnitz, published at Geneva, 1769, in 6 vols. 4to; of the Greek pastoral romance of *Daphnis and Chloe*, by Longus, 1776, 12mo, and of Dacier's translation of the *Manual of Epictetus*, 1775, 18mo. He was also the author of the following works: *Le Caprice Poëtique*, a collection of poems, 1750, 16mo. *Recherches sur l'origine des Découvertes attribuées aux Modernes*, 1766, 2 vols. 8vo, 4th edition, 1812. *Poesies*, 1767, 12mo, and 1677, 8vo. *Le Tocsin*, Rome, 1769, 12mo, reprinted under the title of *Appel au bon Sens*, London, 1777, 8vo. This work was directed against the French philosophers, and was published anonymously. *Explication de quelques médailles de Peuples, de Villes,. et de Rois, Grecques et Pheniciennes*, 1773, 4to. *Explication de quelques médailles du cabinet de Duane*, 1774, 4to. *Trosième Dissertation sur quelques médailles Grecques et Pheniciennes, où se trouvent des observations, pour servir à l'étude de la Paléographie Numismatique*, 1776, 4to. Dutens at the same time published a more complete edition of the two preceding works. *Logique, ou l'Art de Raisonner*, 1773, 12mo, 1777, 8vo, and reprinted also in his miscellaneous works. *Du miroir ardent d'Archimède*, 1755, 1777, 8vo; *Des pierres précieuses et des pierres fines, avec les moyens de les connaître et de les évaluer*, 1776, 12mo, and reprinted at London and Paris. *Itinéraire des routes les plus frequentées, ou Journal d'un Voyage aux principales Villes d'Europe*, 1775, 8vo, and frequently republished with additions and improvements. *Lettre à M. D. B. (Debure) sur la réfutation du livre l'Esprit*, par J. J. Rousseau, 1779, 12mo, which contains some letters of Helvetius and Rousseau. *De l'Eglise, du Pape, de quelques points de controverse, et moyens de réunion de tous les Eglises Chrêtiennes*, 1781, 8vo; several times reprinted, and finally under the title of *Considérations Théologiques sur les moyens de réunir toutes les Eglises Chrêtiennes*, 1798, 8vo. *Œuvres melées*, 1784, 8vo. Under the same title almost the whole works of Dutens were collected and published at London, 1797, 4 vols. 4to. *L'Ami des étrangers qui voyagent en Angleterre*, 1789, 8vo, frequently reprinted. *Histoire de ce qui s'est passé pour le rétablissement d'une régence en Angleterre*, 1789, 8vo. *Recherches sur le tems le plus reculé de l'usage des Voutes chez les anciens*, 1795. *Mémoires d'un Voyageur qui se répose*, Paris, 1806, 3 vols. 8vo. The first two volumes contain the life of the author, written in a romantic style; the third bears the title of *Dutensiana*, and is filled with remarks, anecdotes, bon-mots, and so forth. Dutens is the author of the *Catalogue of Medals* in Swinburne's *Travels*, and of the French text to the second volume of the *Marlborough Gems*. There is a *Memoir* of his in the Collection of the Academy of Inscriptions; and he also published a small tract on the *Iron Mask*. He was a member of the Royal Society of London, and had the title of historiographer to the king. (See Memoirs of Dutens in the *Gentleman's Magazine for* 1812; Chalmers's *Biographical Dictionary;* and *Biographie Universelle.*)

DUTKA, or SCHWERAN, a very ancient Russian wind-instrument, consisting of two flutes of different lengths united together, and having one mouthpiece, and each flute three finger-holes.

DUTY, in *Commerce*. See EXCISE, and TAXATION.

DUUMVIRI (i.e. *the two men*), in *Roman Antiquity*, an appellation given to various magistrates, commissioners, and officers, where two were joined together in the same functions.

DUUMVIRI Capitales were the judges in criminal causes. From their sentence it was lawful to appeal to the people, who alone had the power of condemning a citizen to death. These judges were taken from the body of the decuriones, and had great power and authority: they were members of the public council, and had two lictors to walk before them.

DUUMVIRI Municipales were two magistrates in some cities of the empire, answering to the consuls at Rome. They were chosen out of the body of the decuriones, and their office commonly lasted five years, upon which account they were frequently termed *quinquinales magistratus*. Their jurisdiction was of great extent. They had officers who walked before them, carrying a small switch in their hands; and some of them assumed the privilege of having lictors carrying axes and the fasces or bundles of rods before them.

DUUMVIRI NAVALES were the commissaries of the fleet, first created at the request of M. Decius, tribune of the people, in the time of the war with the Samnites. The duties of their office consisted in giving orders for the fitting out of ships, and issuing their commissions to the marine officers, &c.

DUUMVIRI Sacrorum were magistrates created by Tarquinius Superbus for the performance of the sacrifices, and for keeping the Sibylline books. They were chosen from among the patricians, and held their office during life: they were exempted from serving in the wars, and from the offices imposed on the other citizens: and without them the oracles of the sibyls could not be consulted.

DWALE, in *Heraldry*, the herb deadly nightshade, used for sable or black by such as blazon with flowers and herbs instead of metals and colours.

DWARACA, a town and celebrated temple of Hindustan, province of Gujerat, situated at the south-west extremity of the peninsula of Kattywar. There are 21 villages belonging to Dwaraca, containing 2500 houses, and, on the most accurate calculation, 100,000 inhabitants. The inhabitants were formerly much addicted to piracy, but of late years have been restrained by a treaty with the British. The temple is fabled to have been the residence of Krishna, at which 15,000 pilgrims annually pay their devotions, which is an abundant source of wealth to the Brahmins. N. Lat. 22. 15.; E. Long. 69. 1. (E. T.)

DWARF (Sax. *dwerg, dweorg*), a general name for an animal or a plant greatly inferior in size to that which is usual in their several kinds. Thus there are dwarfs of the human species, dwarf dogs, dwarf trees, &c.

The Romans, in their admiration of dwarfs, whom they called *nani* or *nanæ*, sometimes employed artificial means to check the growth of children whom they designed for dwarfs, by the use of bandages, &c. Dwarfs were also held in high estimation during the middle ages, when they were employed to carry the messages of the knights, and to wait as pages on the feudal nobility. In France, in particular, they shared with the court-jesters the intimacy and favour of the reigning monarch. At Constantinople they are to this day held in much esteem in the seraglio. Augustus's niece, Julia, greatly prized a dwarf called Coropas, who was only two feet and a handbreadth in height, and Andromeda, one of her freed maids was of the same stature. But the most famous of all the ancient dwarfs was Philetus of Cos, who was remarkable, not only for his diminutive size, but in a far higher degree for his learning. He was

likewise distinguished as one of the best poets of his day, and his general character was so high, that he was chosen to superintend the studies of Ptolemy Philadelphus. His person was so light and tiny, that he was obliged to carry leaden weights in his pockets to prevent himself from being blown away by the wind. We have many other accounts of remarkable human dwarfs, but most of them have been deformed in addition. Many relations concerning dwarfs must necessarily be regarded as not less fabulous than those concerning giants. The following remarkable history, however, which there is reason to regard as authentic, is deserving of notice:—

Jeffery Hudson, the famous English dwarf, was born at Oakham in Rutlandshire, in 1619; and about the age of seven or eight, being then but 18 inches high, he was retained in the service of the Duke of Buckingham, who resided at Burleigh-on-the-Hill. Soon after the marriage of Charles I., at an entertainment given to the king and queen at Burleigh, little Jeffery was served up at table in a cold pie, and presented by the duchess to the queen, who retained him as her dwarf. From seven years of age till thirty he never grew taller; but after thirty he shot up to 3 feet 9 inches, and there remained fixed. Jeffery afforded much entertainment at court. Sir William Davenant wrote a poem called *Jeffreidos*, on a battle between him and a turkey-cock; and in 1638 was published a very small book called the *New Year's Gift*, presented at court by the Lady Parvula to the Lord Minimus, commonly called *Little Jeffery*, Her Majesty's servant, written by Microphilus, with a little print of Jeffery prefixed. Before this period Jeffery was employed on a negotiation of great importance—he was sent to France to fetch a midwife for the queen; and on his return with this gentlewoman and Her Majesty's dancing-master, and many rich presents to the queen from her mother Mary de Medicis, he was taken by the Dunkirkers. Jeffery, being thus made of consequence, began to think himself really an important personage. He had borne with little temper the teasing of the courtiers and domestics, and had had many squabbles with the king's gigantic porter. At last, being provoked by Mr Crofts, a young gentleman of family, a challenge ensued; and when Mr Crofts came to the rendezvous armed only with a squirt, the little creature was so enraged that a real duel was the consequence. The appointment was on horseback with pistols, to put them more on a level; and Jeffery, with the first fire, shot his antagonist dead. This happened in France, whither he had attended his mistress in the troubles of the times. He was again taken prisoner by a Turkish rover, and sold into Barbary. But he probably did not remain long in slavery; for at the beginning of the civil war he was made a captain in the royal army; and in 1644 he attended the queen to France, where he remained till the Restoration. At last, upon suspicion of his being concerned in the Popish plot, he was seized in 1682, and confined in the Gatehouse, Westminster, where he died in the sixty-third year of his age. This little hero cuts a considerable figure in Sir Walter Scott's novel of *Peveril of the Peak.*

In the *Memoirs of the Royal Academy of Sciences*, a relation is given by the Count de Tressau of a dwarf called *Bébé*, retained by Stanislaus, king of Poland, and who died in 1764 at the age of twenty-three, when he measured only 32 inches. At the time of his birth he measured only between 8 and 9 inches. Diminutive as were his dimensions, his reasoning faculties were not less scanty, appearing, indeed, not to have been superior to those of a well-taught pointer. But that the size and strength of the intellectual powers are not affected by the diminutiveness or tenuity of the corporeal organs, is evident from a still more striking instance of littleness, given us by the same nobleman, in the person of M. Borulawski, a Polish gentleman, whom he saw at Luneville. This miniature of a man, considering him only with reference to his bodily dimensions, appeared a giant with regard to his mental powers and attainments. He is described by the count as possessing all the graces of wit, united with a sound judgment and an excellent memory; so that we may with justice say of M. Borulawski, in the words of Seneca, and nearly in the order in which he has used them, *posse ingenium fortissimum ac beatissimum sub quolibet corpusculo latere.* His growth was at one year of age, 14 inches; at six, 17 inches; at twenty, 33 inches, and at thirty, 39 inches. He had a sister named Anastasia, so much shorter in stature than himself that she could stand under his arm. Borulawski visited many of the courts of Europe, and finally died in England in 1837 at the advanced age of ninety-eight.

There is preserved to this day in the Louvre at Paris a picture by Francesco Torbido of a favourite dwarf of Charles V. of Spain, by name Corneille. He is represented on foot, dressed in the costume of a knight, his left hand resting on the back of a large dog, which serves to indicate the stature of the dwarf.

Another remarkable dwarf was Jean d'Estrix, a native of Malines, who was exhibited to the Duke of Parma in 1592. He was at that time thirty-five years of age, and measured barely three feet in height. He did not, however, show any traces of the stupidity usually attributed to dwarfs, but was remarkable for his general intelligence, and especially for his skill in the languages of modern Europe. But the smallest of all the dwarfs of whom any record has been preserved, was an Englishman named Birch, who when full-grown measured only twenty inches.

DWIGHT, Timothy, D.D., one of the most distinguished Presbyterian divines that America has yet produced, was born in 1752, at Northampton, in the state of Massachusetts. From his mother, who was a daughter of Jonathan Edwards, he inherited those principles and that piety which he developed in his writings and manifested in all his actions. He studied at Yale College; which he had no sooner left than he was appointed teacher of a grammar-school at New Haven, where he remained for two years. At the early age of nineteen he was appointed tutor in Yale College, where he distinguished himself by the skill with which he taught the higher mathematics. In this same year he began his epic poem entitled the *Conquest of Canaan*, which was published in 1795. In 1777 he was licensed to preach the gospel, and accepted the office of chaplain to the forces; in which situation he remained till obliged by his father's death to return home and exert himself for the support of his family. Towards the close of the war of independence he was twice elected a member of the legislature. In 1783 he was ordained minister of Greenfield in Connecticut, when he opened an academy which speedily acquired a very high reputation, and attracted scholars from all parts of the Union. In 1795 he was elected president of Yale College, and by his judicious management restored that institution to the high place from which it had fallen before his appointment. Besides his *Travels in New England and New York*, written from notes taken in these countries during a series of journeys undertaken for the recovery of his health, Dr Dwight published a valuable treatise entitled *Theology Explained and Defended in a series of Sermons*, 5 vols. 8vo. It is upon this work that his fame as a theologian chiefly depends. After a long and honourable career, Dr Dwight died in the ninetieth year of his age. In 1827 two additional volumes of sermons (a small portion, however, of the MSS. which he left behind) were published, and were exceedingly well received in England as well as the United States.

DWINA, or Dvina, two rivers of Russia. See Russia.

DYEING.

History.

Is the art of communicating a new and permanent colour to any substance whatever; but it is usually confined to the art of giving colours to wool, silk, feathers, cotton, or flax, or the thread or cloth formed of any of these substances. To this more limited signification we shall restrict ourselves in the following treatise. For dyeing or staining *paper, wood, bone, leather, marble,* &c. the reader is referred to these articles. We shall divide this article into six chapters. In the first we shall give a rapid sketch of the history of the art; in the second we shall treat of the nature and properties of wool, feathers, silk, cotton, and flax, of which the fabrics to be dyed are composed; in the third chapter we shall treat of *mordants*, or the substances by means of which the colours are fixed on the cloth or thread. The fourth chapter will be occupied with the mode of dyeing the simple colours, or *red, yellow, blue, black,* and *brown.* The object of the fifth chapter will be the compound colours, or the different shades of *green, purple, orange,* and *gray.* The sixth chapter will be occupied with a sketch of the processes of calico-printing. The first five chapters were written by the late Thomas Thomson, professor of chemistry in the University of Glasgow, and the sixth, embracing all the latest improvements, by Professor F. Crace Calvert, Royal Institution, Manchester.

CHAPTER I.

HISTORY OF DYEING.

Nature has implanted in man a sense of pleasure which he derives from beholding lively colours properly displayed and contrasted. And this sense receives ample gratification from the gay plumage of the feathered tribes, and the endless variety displayed in the blossoms of the vegetable kingdom. The diversity in the colours of flowers must have early attracted the attention of man, and he could scarcely avoid feeling a desire to employ them to adorn his person; but their fading nature fitted them only for a temporary ornament. It would naturally occur to attempt to transfer some of the most lively colours of the vegetable kingdom either to the skin of the naked savage, or to the different articles of dress with which he covered himself up from the cold, or with which he decorated his person.

A few trials would speedily show that the gay colours of most flowers could not be transferred to any article of dress, at least without a great diminution of their splendour; but a considerable difference would be observed depending upon the colour of the flower. The *red* flowers would either lose their colour altogether, as they would communicate to cloth, not a *red,* but a *blue* colour. The yellow coloured berries, on the other hand, would be found in some instances to communicate a very lively and beautiful, though not a permanent colour.

By multiplying trials, various roots, barks, and fruits would be found capable of communicating certain colours to cloth. These facts would be treasured up, and thus a beginning would be made of the art of *dyeing.* Accordingly we find this art practised to a greater or smaller extent in the most remote ages, and among the most savage and barbarous nations. Even the lowest of the American tribes, in point of civilization, understood how to communicate several very fine colours, and considerable improvements in dyeing were borrowed from the Americans.

Produced early in Egypt.

It would be in vain, therefore, to attempt to discover to whom the art of dyeing is indebted for its origin, as the practice of it precedes the origin of history. From the writings of Moses, who led the Israelites out of Egypt about 1555 years before the commencement of the Christian era, it is obvious that the art of dyeing had in his time made great progress in Egypt. He mentions blue, and purple, and scarlet, and badgers' skins dyed red.[1] There are some reasons for believing that what is translated in the Old Testament *fine linen* was in reality a cloth made of cotton wool. Indeed it is certain that cloth made of cotton was used in India and Egypt in the most remote ages. Cotton wool would naturally attract the attention of mankind in those countries where the plant which yields it grows. Now we know that the cotton plant is a native of India. India and Egypt are countries in which the processes of dyeing are as likely to have originated as any other; for they constitute the cradle of the human race, and civilization appears to have made earlier progress in them than in any other.

Tyrian dye.

The art of dyeing was brought to a considerable degree of perfection at a very early period in Phœnicia. It appears that it was in Tyre where the method of dyeing woollen cloth *purple* was first discovered; and this discovery, there is reason to believe, is at least as old as the time of Moses. The purple was communicated by means of several species of univalve shell-fish, which no doubt abounded on the coast of Phœnicia. Pliny, in the thirty-sixth chapter of his sixth book, gives us an account of two species of shell-fish from which the purple was obtained. The first species was called *buccinum,* doubtless from some resemblance to a hunting horn; the second was called *purpura.* A single drop of the dyeing liquor was obtained from each fish by opening a vessel situated in the throat of the animal. The liquor, when extracted, was mixed with a considerable portion of salt, to prevent putrefaction. It was then diluted with five or six times as much water, and kept moderately hot in leaden or tin vessels, for the space of ten days, during which the liquor was frequently skimmed, to separate all impurities. After this, the wool, being first washed, was immersed and kept in the liquor for five hours. It was then taken out, carded, and again immersed and kept in the liquor till all the colouring matter was extracted. To produce particular shades of colour, carbonate of soda, urine, and a marine plant called *fucus,* were occasionally added. Several of these colours are particularly described by Pliny, though it is difficult to form an accurate conception of his meaning. The *purple* itself seems to have been similar to the colour of blood.

Pliny says the Tyrians first dyed their wool in the liquor of the *purpura,* and afterwards in that of the *buccinum.* We find allusions to this practice in several passages of the Old Testament. Doubtless Horace alludes to the same process when he says,

> .... te bis Afro
> Murice tinctæ
> Vestiunt lanæ.
>
> *Od.* ii. 16, line 35.

[1] Exodus, xxv. 4 and 5.

History.

The shell-fish employed in this process were found abundantly both on the European and African shores of the Mediterranean. They still exist on these shores, and have been also met with abundantly on the coasts of England and France.

Purple.

The purple mentioned in Exodus was probably that dyed by the Tyrians. Ezekiel, who wrote about 593 years before the Christian era, in his prophecy against Tyre, says, "Fine linen with broidered work from Egypt, was that which thou spreadest forth to be thy sail; blue and purple from the isles of Elishah, was that which covered thee."[1] By Elishah it is generally supposed that Elis, on the west side of the Greek Peloponnesus, was meant. Hence it would appear that the Tyrians in Ezekiel's time drew their supply of shell-fish for dyeing purple from the coast of Greece.

From Herodotus it appears that purple was worn in Greece 559 years before the Christian era. It gradually made its way to Rome, and was purchased with avidity, notwithstanding its high price. After the establishment of the emperors upon the ruins of Roman liberty, the use of the purple was limited to the emperor, people of inferior rank being prohibited from wearing it, on pain of death. This of course sadly diminished the extent of the manufactory. It continued to languish for some centuries, and then became extinct; and the mode of dyeing the Tyrian purple was lost for many ages, but was again revived during the seventeenth century by Mr Cole of Bristol, and during the eighteenth century by M. Reaumur of France. But by this time finer colours had been discovered, and cheaper processes brought into use. It was not therefore thought advisable by the dyers to resume the methods followed by their Tyrian predecessors.

With the exception of the processes followed in the dyeing of purple, we are ignorant of the practices of the ancient dyers, or of the degree of progress which this *art* had made. Pliny, under whose province an account of dyeing naturally came, has passed it over in silence, and has assigned as a reason for his conduct that it was not reckoned among the liberal arts. *Nec tingendi rationem omisissemus, si unquam ea liberalium artium fuisset.*

Dyeing introduced into Greece.

The fine colours given in India to cotton cloths are universally known. The methods practised are no modern inventions, but were in common use when India was visited by Alexander the Great, and probably many ages before. These colours, which are both beautiful and permanent, prove that the methods of fixing gaudy colours on cotton were pretty far advanced. But these methods, as they have been described by Beaulieu and Bancroft, are so complicated, tedious, and imperfect, that they could be followed only where the wages of labour are exceedingly low, and never would answer in any part of Europe. There is reason to believe that the processes of dyeing cotton and linen were introduced into Greece only after the expedition of Alexander the Great into India.

The common people in Athens were very idle and very poor, spending their time in the public places, and receiving a daily pension of three oboli, or about fourpence halfpenny. But this sum would have purchased as much corn as three times the amount would do in this country; so that the income of a common Athenian citizen was equivalent to about thirteen pence halfpenny of our money. They went barefooted, and were dressed in garments which never had been dyed, but which were occasionally washed. The rich citizens wore garments which had been dyed; and the most common colour was *scarlet*, communicated to the cloth by *kermes*, a dyestuff still in use, and which we shall describe in a subsequent part of this treatise. This colour, as Pliny informs us, was scarcely less esteemed than the Tyrian purple. Cloths of the scarlet colour were worn by the emperors; and scarlet and purple seem to have been often confounded together.

The modes of dyeing black, blue, yellow, and green, were brought by Alexander the Great into Greece from India, as Pliny informs us.

Among the Romans, new-married women wore a *yellow* veil, and this colour was reserved for the women. In the circus the four different factions were distinguished by four different colours, one belonging to each faction. These were the green (*prasinus*), the orange (*rufatus*), the blue (*venetus*), and the white. These factions, with their colours, were transferred to Constantinople, and long distracted that city.[2] We are ignorant of the dyestuffs by means of which these colours were given to cloth.[3]

The want of soap, which was unknown to the Greeks, and only known to the Romans in Pliny's time as a pomatum for the hair, must have greatly cramped the processes of the ancient dyers; nor have we any evidence that *alum* was known to them, though they must have employed some substitute, otherwise the red colour of the kermes could not have been fixed upon the cloth. Alum appears to have been well known to Geber, who wrote in the eighth century. He mentions different manufactories of it, and talks of it as a substance familiarly known in his time. Is it not possible that the mode of making it had been known to the Tyrian dyers, but kept by them as a profound secret? The purple and scarlet dye was still in use during Geber's time, and even continued to be practised in the eleventh century. Alum, then, was certainly used by the Tyrian dyers before their manufactory was finally extinguished; but even if we admit that the ancients were unacquainted with *alum*, yet it is obvious, from Pliny's account of *alumen*, that it was a substance found native; that there were different species of it, for he enumerates four or five, and one of these may have been a native combination of sulphuric acid and alumina, which (if pure) would doubtless answer all the purposes of a mordant.

The ancient dyeing processes, such as they were, continued to be practised in Constantinople as long as the Greek empire lasted. It was during the crusades that the republics of Venice and Genoa reached the highest summit of their power. They were trading and manufacturing communities, and made a point of making themselves acquainted with the different arts at that time practised in Greece. Dyeing was not neglected by them; but the art and trade of the dyers of Constantinople were transferred by them to Italy.

Discovery of archil.

About the year 1300 a merchant of Florence accidentally discovered the method of making *archil*. He observed that a certain species of lichen (*lichen roccellus*), when macerated in urine, acquired a fine purple colour. This led him to try various experiments, which terminated in the discovery of archil, and in the application of it to the art of dyeing.

First treatise on dyeing

In the year 1429 the first collection of processes employed in dyeing was published in Venice, under the title *Mariegola dell' arte dei Tentori*. A second edition of this book, with many additions, was published in 1510. Giovan Ventura Rosetti formed the project of making this

[3] Berthollet has given a catalogue of the dyestuffs of the ancients, after Bischoff, *Elements de l'Art de la Teincture*, i. 14. We do not consider it as worth transcribing, because it is altogether conjectural.

History.

work more complete and more useful. He travelled into those parts of Italy and the neighbouring countries where attention was paid to the processes of dyeing, in order to acquire the requisite information. The result of his acquisitions was published under the name of *Plictho dell arte de' tentori, che insegna tenger panni, tele banbasi e sede, si per l'arte magiore, come per la commune.* It was published at Venice in the year 1548.

Introduction of indigo and cochineal.

In the Plictho no notice is taken either of cochineal or indigo. Hence we may conclude that, in 1548, neither of these important dyestuffs had made their way into Europe. Pliny mentions indigo under the name of *indicum;* but it appears to have been used by the Greeks and Romans only as a paint; yet there can be little doubt that in India it had been employed from time immemorial as a dyestuff. Cochineal could not be known till after the discovery of America. It was used by the Mexicans as a dyestuff. In 1523 Cortes received orders from the court of Spain to multiply this precious insect, to collect it, and send it to Spain.

Cochineal by itself gives only a *crimson* colour; it dyes *scarlet* when mixed with a solution of tin. This fact was discovered accidentally by Cornelius Drebbel about the year 1630. He communicated his observation to his son-in-law Kuffelar, who was a dyer at Leyden. He soon brought the process to perfection, kept it a secret, and brought the scarlet colour into fashion. Soon after, the same process was discovered by a German chemist called Keffler, who carried his secret to London in 1643. A Flemish dyer called John Kloeck got information of the process in 1647, and it gradually made its way through every country of Europe.

Indigo, though a much more important dyestuff than cochineal, did not make its way into general use without the greatest difficulty. The use of it was prohibited in England during the reign of Elizabeth; and the prohibition was not taken off till the time of Charles II. It was equally prohibited in Saxony, where it was styled in the prohibition a corrosive substance, and called food for the devil. Restrictions on the use of indigo in dyeing were imposed also in France, though it was not altogether prohibited, as it had been in England and Saxony.

Improvements in France.

The improvements in dyeing which took place in France may be dated from the administration of Colbert, who paid particular attention to the different branches of manufacture which were carried on by the French. In the year 1672 he caused a book of instructions for dyers to be published in Paris. This book was republished in 1708 under the following title: *Le teincturier parfait, ou instruction nouvelle et générale pour la teincture des laines et manufactures de laine de toutes couleurs, et pour la culture des drogues ou ingredients qu'on y emploie.*

But Colbert's encouragement of dyeing was clogged with restrictions and prohibitions which would have been fatal to the art, had it not been for the facility with which they were evaded. The revocation of the edict of Nantes in the year 1685 was a fatal blow to the pre-eminence of France in manufactures. The most industrious and skilful workmen and artists were driven out of the country, and carried their knowledge and dexterity into Great Britain, Holland, and Prussia. Succeeding administrations endeavoured as far as possible to correct the fatal policy of Louis XIV. The art of dyeing in particular drew their attention, and the most eminent chemists which the country possessed were placed as a kind of superintendents of the art of dyeing. Their business was to endeavour to improve the processes, and to bring the art to a state of perfection. Dufay, Hellot, Macquer, and Berthollet, successively filled this important office; and each of these eminent men contributed somewhat to the improvement of the theory of dyeing. Dufay first formed tolerably accurate notions of the nature of colouring matters, and of the forces which made them attach themselves to cloth. Hellot published a well-arranged treatise on dyeing woollen cloth, such as it was practised in the best dyeing establishments in France; and Macquer gave an equally detailed account of the processes followed by the silk dyers.

Substances to be coloured.

Berthollet, who was named his successor as superintendent of dyeing, published an excellent treatise under the title of *Elements de l'Art de la Teincture,* a second edition of which appeared in the year 1804.

Scarcely any work upon dyeing deserving the name of a scientific treatise appeared in the English language till Bancroft published his *Experimental Researches concerning the Philosophy of Permanent Colours, and the best means of producing them by dyeing, calico-printing,* &c., in 1794.

Great improvements have been made of late years in calico-printing, which will be noticed at the conclusion of this article.

CHAPTER II.

OF THE NATURE AND PROPERTIES OF THE SUBSTANCES TO WHICH COLOURS ARE COMMUNICATED.

There has been much speculation among philosophical dyers respecting the nature of the colouring matters, and the way in which the different colours are induced by dyeing; but these speculations have not led to any information of much value. There is reason for believing that the colouring matters employed as dyestuffs are all transparent, and that the colour is produced by their action on the light transmitted through them from the white fibres of the cloth. Those colouring matters that transmit all the rays equally leave the cloth white; if the blue ray be transmitted and the rest absorbed, the colour of the cloth will be *blue,* and so on. This is all that we know about the mechanical nature of the dyestuffs.

Silk and wool dye better than cotton and linen.

With respect to the aptitude of being dyed, and the brilliancy of the colours thus communicated, there is found to be very great difference in different tissues. Animal substances are much more easily dyed than vegetable substances. Of animal substances, *silk* receives colour and the shades given are brighter and more beautiful than those which can be imbibed by any other tissue. Woollen cloth is also very fit for being dyed, and receives very brilliant colours with avidity; though in this respect it is inferior to silk. Cotton and linen are much more difficult to dye, and cannot be made to imbibe such brilliant colours as silk or woollen. Thus the rich scarlet given to cloth by the combined action of cochineal and the oxide of tin, has never been communicated to cotton cloth or linen. The Turkey-red dye, which is by far the finest and most permanent red that has ever been communicated to cotton cloth, is a crimson, or rather a crimson with a shade of brown. It has not the least approach to a scarlet.

SECT. I.—*Of Wool.*

Structure.

Wool, which is well known as the covering of sheep, derives its value from the length and fineness of its filaments. The filaments of wool are considerably elastic, for they may be drawn out beyond their usual length, and when the force is removed they recover it again. The surface of the filaments of wool or hair is not perfectly smooth; for although no roughness or inequality can be discovered by the microscope, yet they seem to be formed of small laminæ placed over each other in a slanting direction, from the root of the filament towards its point, resembling the arrangement of the scales of a fish, which cover each other from the head of the animal to its tail; or perhaps they consist of zones placed over each other.

Substances to be coloured.

as is observed in the horns of animals. This peculiarity of structure of the filaments of hair and wool is proved by a simple experiment. If a hair be laid hold of by the root in one hand, and drawn between the fingers of the other hand, from the root towards the point, scarcely any friction or resistance is perceived, and no noise is heard; but if it be grasped by the point, and passed in the same manner between the fingers from the point towards the root, a resistance is felt, and a tremulous motion is perceptible to the touch, while the ear is sensible to a slight noise. Thus it appears, that the texture of the surface of hair or wool is not the same from the root towards the point, as it is from the point towards the root. This is further confirmed by another experiment. If a hair be held between the thumb and fore finger, and they are rubbed against each other in the longitudinal direction of the hair, it acquires a progressive motion towards the root. This effect depends not on the nature of the skin of the finger, or on its texture, for if the hair be turned, and the point placed where the root formerly was, the motion is reversed, that is, it will still be towards the root.

Felting.

On this peculiarity of structure, which was observed by M. Monge, depend the processes of felting and fulling, to which hair and wool are subjected for different purposes. In the process of felting, the flocculi of wool are struck with the string of the bow, by which the filaments are separately detached, and dispersed in the air. These filaments fall back on each other in all directions on the table, and when a layer of a certain thickness is formed, they are covered with a cloth, on which the workman presses with his hands in all parts. By this pressure the filaments of wool are brought nearer to each other; the points of contact are multiplied; the progressive motion towards the root is produced by the agitation; the filaments entangle each other; and the laminæ of each filament taking hold of those of the other filaments, which are in an opposite direction, the whole is retained in the state of close contexture.

Fulling.

Connected with this operation is that of fulling. The roughness on the surface of the filaments of wool, and their tendency to acquire a progressive motion towards the root, produce considerable inconvenience in the operations of spinning and weaving. These inconveniences are obviated by covering the filaments with a coat of oil, which fills up the cavities, and renders the asperities less sensible. When these operations are finished, the stuff must be freed from the oil, which would prevent it from taking the colour with which it is to be dyed. For this purpose it is taken to the fulling-mill, where it is beaten with large beetles, in a trough of water, through which clay has been diffused. The clay unites with the oil, which being thus rendered soluble in the water, is carried off by fresh portions of water, conveyed to it by proper apparatus. In this way the stuff is scoured; but this is not the sole object of the operation. By the alternate pressure of the beetles, an effect similar to that of the hands in the operation of felting is produced. The filaments composing a thread of warp or woof, acquire a progressive motion, are entangled with the filaments of the adjoining threads, those of the latter into the next, and so on, till the whole threads are felted together. The stuff is now contracted in all its dimensions, and, participating both of the nature of cloth and of felt, may be cut without being subjected to ravel; and, when employed to make a garment, requires no hemming. In a common woollen stocking web, after this operation, the stitches, when one happens to slip, are now no longer subject to run, and the threads of the warp and woof being less distinct from each other, the whole stuff is thickened, and forms a warmer clothing.

Importance of wool.

The various manufactures of which wool constitutes the basis are justly regarded as among the most important to man in civilized society. Accordingly, the production of fine wool, and the causes which retard or improve the breed of sheep from which it is obtained, have greatly occupied the attention of economists and philosophers in our own, as well as in other countries. The wool of different breeds of sheep, in different countries, it is well known, possesses very different qualities, both with regard to the fineness of the filament, and the colour. Some is of a white or yellow, and some of a reddish and black colour. Excepting the wool of the breed of sheep in Andalusia, the Spanish wool was formerly all of a brownish-black colour. This was preferred by the native Spaniards; and even at this day, the dress of some religious orders in Roman Catholic countries consists of cloth manufactured from this wool, and retaining its natural colour. But for the purposes of dyeing, white wool is now always preferred, because it is found susceptible of receiving better and more durable colours.

Scouring.

Wool is naturally covered with a kind of grease or oil, which is found to preserve it from insects or moths, and on this account this greasy matter is not removed, or the wool is not scoured, till it is to be dyed or spun.[1] The process for scouring wool is the following: It is put for about a quarter of an hour into a kettle, with a sufficient quantity of water, to which a fourth part of putrid urine has been added. It is then heated to such a degree as the hand can bear, occasionally stirred, and, after being taken out, is allowed to drain. It is then put into a basket, and exposed to a stream of running water, and moved about till the grease is so completely separated that it no longer renders the water turbid. After being drained, it is sometimes found to lose by this operation above one fifth of its weight. It is almost unnecessary to observe, that the more carefully and completely this process is performed, the better the wool is fitted to receive the colouring matter. Our chemical readers will readily perceive the nature of the changes which are effected in this process of scouring. The ammonia, or volatile alkali, which exists in the urine, combines with the oil of the wool, and forms a soap, which being soluble in water, is dissolved and carried off.

Dyeing.

Wool is either dyed in the fleece, or after it is spun into threads, or when it has been manufactured into cloth. For the purpose of forming cloths of mixed colours, it is dyed before it is spun; for the purposes of tapestry, it is dyed in the state of thread; but most commonly it is subjected to this process after it has been manufactured into cloth. In these different states the quantity of colouring matter which is taken up is very different. The proportion is largest when it is dyed in the fleece, because then the filaments being more separated, a greater surface is exposed to the action of the colouring particles. For a similar reason the quantity of colouring matter taken up is greater when in the state of thread or yarn, than when it is formed into cloth. But cloths themselves must vary greatly in this respect, according to their different qualities. Their different degrees of fineness, or closeness of texture, will produce considerable variations; and besides, the difference in the quantity and dimensions of the substances to be dyed, the different qualities of the ingredients employed in the process, and the different circum-

[1] According to an observation of Reaumur, rubbing any stuff with greasy wool is sufficient to preserve it from moths.

Substances to be coloured.

stances in which it is performed, should be a caution against trusting to precise quantities, regulated by weight or measure, which are recommended according to general rules. According to the fineness of the texture of the wool, and the nature of the colouring matter employed, it is found to be more or less penetrated with this matter. The coarse wool from the thighs and tails of some sheep receives colours with difficulty, and the finest cloth is never completely penetrated with the scarlet dye. The interior of the cloth appears always, when cut, of a lighter shade, and sometimes even white.

Sect. II.—*Of Silk.*

Origin.

Silk, which forms the basis of one of the richest and most splendid parts of dress among the wealthy and luxurious in civilized society, is the production of different species of insects. The *phalæna bombyx*, or silk-worm, which is a native of China, attracted the attention of mankind in that country from the earliest ages. The honour of having first collected and prepared silk from the cocoons or balls in which it is wound up by the insect, during its metamorphosis, is ascribed by the Chinese historians to the wife of an emperor. The *phalæna atlas*, Lin. which is also a native of China, is said to form larger cocoons, and to yield a stronger silk. The silk-worm was first carried from China to Hindustan, and afterwards to Persia. Silk seems not to have been known to the Greeks or Romans till the time of Augustus. Its nature and origin were little understood; and for many ages it was so scarce that it could only be purchased at a price which was equal to its weight in gold. The emperor Aurelian, it is said, from a principle of economy, resisted the urgent solicitations of his empress, who wished to have a silken robe, alleging the extravagance of the expense. About the middle of the sixth century, two monks returned from India to Constantinople, and brought with them a considerable number of silk-worms, with instructions for managing and breeding them, as well as for collecting, preparing, and manufacturing the silk. Establishments were thus formed at Corinth, Athens, and other parts of Greece. The crusades, which greatly contributed to the diffusion of different kinds of knowledge, by the intercourse which took place between different countries, proved useful in disseminating the knowledge of rearing the silk-worm, and preparing and manufacturing its valuable productions. Roger, king of Sicily, about the year 1130, returning from one of these frantic expeditions, brought with him from Athens and Corinth several prisoners, who were acquainted with the management of silk-worms and the manufacturing of silk. Under their superintendence manufactories were established at Palermo and Cagliari in Sicily. This example was soon adopted and followed in different parts of Italy and Spain. In the time of James I. an attempt was made to establish the silk-worm in England. For this purpose the culture of the mulberry-tree, on which the insects feed, was strongly recommended by that prince to his subjects; but the attempts which were made have been hitherto unsuccessful.

Scouring.

The fibres of silk are covered with a coating or natural varnish of a gummy nature. To this are ascribed its stiffness and elasticity. Besides this varnish, the silk which is usually met with in Europe is impregnated with a substance of a yellow colour; and for most of the purposes to which silk is applied, it is necessary that it should be deprived both of the varnish and of the colouring matter. On this account it must be subjected to the operation of scouring; but for silks which are to be dyed this process should not be carried so far as for those which are merely to be whitened; and different colours, it is observed, require different degrees of this operation. The quantity of soap constitutes the chief difference. A hundred pounds of silk boiled in a solution of twenty pounds of soap for three or four hours, adding new portions of water during the evaporation, are sufficiently prepared for receiving common colours. For blue colours, the proportion of soap must be increased; and scarlet, cherry colour, &c. require a still greater proportion, for the ground must be whiter for these colours.

Process when employed white.

Silk which is to be employed white must undergo three operations. In the first the hanks are immersed in a hot but not boiling solution of thirty pounds of soap to a hundred of silk. When the immersed part is freed from its gum, which is known by its whiteness, the hanks are shaken over, as the workmen term it, so that the part which was not previously immersed may undergo the same operation. They are then wrung out as the process is completed. In the second operation the silk is put into bags of coarse cloth, each bag containing twenty or thirty pounds. These bags are boiled for an hour and a half in a solution of soap prepared as before, but with a smaller proportion of soap; and, that they may not receive too much heat by touching the bottom of the kettle, they must be constantly stirred during the operation. The object of the third operation is to communicate to the silk different shades, to render the white more agreeable. These are known by different names, as China-white, silver-white, azure-white, or thread-white. For this purpose a solution of soap is also prepared, of which the proper degree of strength is ascertained by its manner of frothing by agitation. For the China-white, which is required to have a slight tinge of red, a small quantity of anotta is added, and the silk is shaken over in it till it has acquired the shade which is wanted. In other whites a blue tinge is given by adding a little blue to the solution of soap. The azure-white is communicated by means of indigo. To prepare the azure, fine indigo is well washed two or three times in moderately warm water, ground fine in a mortar, and boiling water poured upon it. It is then left to settle, and the liquid part only, which contains the finer and more soluble parts, is employed.

Some use no soap in the third operation; but when the second is completed, they wash the silks, fumigate with sulphur, and azure them with river water, which should be very pure. But all these operations are not sufficient to give silk that degree of brightness which is necessary, when it is to be employed in the manufacture of white stuffs. For this purpose it must undergo the process of sulphuration, in which the silk is exposed to the vapour of sulphur; for an account of which see Bleaching. But before the silk which has been treated in this way is fit for receiving colours, and retaining them in their full lustre, the sulphur which adheres to it must be separated by immersion and agitation for some time in warm water, otherwise the colours are tarnished and greatly injured.

Mode of extracting its colouring matter.

It has long been an object of considerable importance to deprive silk of its colouring matter, without destroying the gum, on which its stiffness and elasticity depend. A process for this purpose was discovered by Beaumé, but as it was not made public, others have been led to it by conjecture and experiment. The following account, given by Berthollet, is all that has transpired concerning this process. A mixture is made with a small quantity of muriatic acid and alcohol. The muriatic acid should be in a state of purity, and particularly should be entirely free from nitric acid, which would give the silk a yellow colour. In the mixture, thus prepared, the silk is to be immersed.

One of the most difficult parts of the process, espe-

Substances to be coloured.

cially when large quantities are operated upon, is to produce a uniform whiteness. In dyeing the whitened silk, there is also considerable difficulty to prevent its curling, so that it is recommended to keep it constantly stretched during the drying. The muriatic acid seems to be useful in this process, by softening the gum, and assisting the alcohol to dissolve the colouring particles which are combined with it. The alcohol which has been impregnated with the colouring matter may be again separated from it and purified, that it may serve for future operations, and thus render the process more economical. This may be done by means of distillation, with a moderate heat, in glass or stoneware vessels.

Aluming.

The preparation with alum is a very important preliminary operation in the dyeing of silk. Without this process few colours would have either beauty or durability. Forty or fifty pounds of alum, previously dissolved in warm water, are mixed in a vat with forty or fifty pailfuls of water; and to prevent the crystallization of the salt, the solution must be carefully stirred during the mixture. The silk being previously washed and beetled, to separate any remains of soap, is immersed in this alum liquor, and at the end of eight or nine hours is wrung out, and washed in a stream of water. A hundred and fifty pounds of silk may be prepared in the above quantity of liquor; but when it begins to grow weak, which may be known by the taste, twenty or twenty-five pounds of dissolved alum are to be added, and the addition repeated till the liquor acquires a disagreeable smell. It may then be employed in the preparation of silk intended for darker colours, till its whole strength is dissipated. This preparation of silk with alum must be made in the cold; for when the liquor is employed hot, the lustre is apt to be impaired.

Sect. III.—*Of Cotton.*

Origin.

Cotton is the down or wool contained in the pods of a shrubby plant, which is a native of warm climates. Of this genus of plants (*Gossypium*, Lin.) there are four species, one of which only is perennial; the other three are annual plants; but of these there are many varieties, occasioned by the difference of soil or temperature in which they are produced. The principal differences among cottons consist in the length and firmness of the filaments, and in their strength and colour.

Structure.

The peculiar structure of the fibres of cotton is now well known. According to the microscopic observations of Leeuwenhoeck, they have two sharp sides, to which are ascribed the irritation and inflammation of wounds and ulcers when they are dressed with cotton instead of lint. This peculiarity of structure, it is also supposed, may occasion some difference in the conformation and number of the pores, on which alone the disposition of cotton to admit and retain colours better than linen seems to depend. In this respect, however, it is inferior to wool and silk, because, on account of its vegetable nature, its affinity for colouring matter is less powerful.

Has a less affinity than wool for colouring matter.

It is well known that silk, cotton, and linen have a weaker affinity for colouring matter than wool. Le Pileur d'Apligny attempts to explain this by supposing that the pores of these substances are smaller than those of wool, and that the colouring particles enter them less easily and freely. But according to the observation of Dr Bancroft, the reverse of this seems to be the fact; for there is little difficulty in making silk, cotton, and linen imbibe colouring matter, even when it is applied cold, without any artificial dilatation of the pores, which is always necessary in the dyeing of wool. The only real difficulty is to make them retain the colours after the matter has been imbibed; because being admitted so readily into their undilated pores, the particles cannot be afterwards compressed and retained by the contraction of these pores, as is the case with wool. It requires double the quantity of cochineal which is necessary for wool to communicate a crimson colour to silk; a certain proof that it can take up a greater quantity, and consequently that the pores are sufficiently large and accessible. Unbleached cotton is always preferred for dyeing Turkey red, because in this state the colour is found to be most permanent; and this is ascribed to the pores or interstices being less open than after it has undergone the process of bleaching. The same thing is observed of raw or unscoured silk. It is found to combine more easily with the colouring matter, and to receive a more permanent colour in this state, than after it has been scoured and whitened. "The openness of cotton and linen," says Dr Bancroft, "and their consequent readiness to imbibe both colouring particles and the earthy or metallic bases employed to fix most of them, are circumstances upon which the art of dyeing and calico-printing is in a great degree founded."[1] But is not this too mechanical an explanation of the phenomenon? Might it not rather be alleged that it is owing to a difference of affinities which exists between the particles of colouring matter and the substance which is separated from the silk or cotton by the process of bleaching or scouring? This substance probably acts the part of a mordant; and having a stronger affinity for the stuff and for the colouring matter than the stuff has for the latter, the colour communicated is more durable when silk or cotton is dyed in the unbleached or unscoured state.

Preparations for dyeing.

To prepare cotton stuffs for receiving the dye, several operations are necessary. It must first undergo the process of scouring. By some it is boiled in sour water, or in alkaline ley. It should be kept boiling for two hours, then wrung out, and rinsed in a stream of water till the water comes off clear. The stuffs to be prepared should be soaked for some time in water, mixed with not more than $\frac{1}{50}$th part of sulphuric acid, and then carefully washed in a stream of water, and dried. In this operation the acid combines with a portion of calcareous earth and iron, which would have interrupted the full effect of the colouring matter in the process of dyeing.

Aluming

Aluming is another preliminary process in the dyeing of cotton. The alum is to be dissolved in the manner already described in preparing silk. Each pound of cotton stuff requires four ounces of alum. By some a solution of soda, about $\frac{1}{16}$th part of the alum, and by others a small quantity of tartar and arsenic, are added. The thread is to be impregnated by working it in small quantities with this solution. The whole is then put into a vessel, and the remaining part of the liquor is poured upon it. In this state it is left for twenty-four hours, after which it is removed to a stream of water, and allowed to remain for an hour and a half, or two hours, to extract part of the alum. It is then to be washed. By this operation cotton is found to gain an addition of about $\frac{1}{40}$th part of its weight.

Galling.

The operation of galling is another preparatory process in the dyeing of cotton stuffs. The quantity of astringent matter employed must be proportioned to its quality, and the amount of the effect required. Powdered galls are boiled for two hours in a proportion of water, regulated by the quantity of thread to be galled. This solution being reduced to such a temperature as the hand can bear, is

[1] *Philosophy of Permanent Colours*, p. 71.

Substances to be coloured.

divided into a number of equal parts, that the thread may be wrought pound by pound. The whole stuff is then put into a vessel, and the remaining liquor poured upon it, as in the former process. It is then left for twenty-four hours if it is to be dyed black, but for other colours twelve or fifteen hours are found sufficient. It is then wrung out and dried.

In the galling of cotton stuffs, which have already received a colour, the precaution should be observed of performing this operation in the cold, otherwise the colour is subject to injury.

Berthollet informs us, that cotton which had been alumed acquired more weight in the galling than that which had not previously undergone that process; for although alum adheres but in small quantities to cotton, it communicates to it a greater power of combining both with the astringent principle and with the colouring particles. This, we may add, may be considered as a good instance of the action of intermediate affinities, and of the advantage to be derived to the art of dyeing, from investigating and observing this action.

Sect. IV.—*Of Flax.*

Origin. Flax and hemp nearly resemble each other in their general properties: and, so far as relates to the process of dyeing, what is said of the one may be applied to the other. Flax or lint is obtained from the bark of *Linum usitatissimum*, and hemp from that of *Cannabis sativa.*

Watering. Before flax is properly prepared to receive the dye, it must be subjected to several processes. One of the most important is that of watering, by which the fibrous parts of the plant are separated, and brought to that state in which they can be spun into threads. As the quantity and quality of the product depend much on this preliminary operation, it becomes of the greatest consequence that it be properly conducted. During this process carbonic acid and hydrogen gas are given out. The extrication of these gases is owing to a glutinous juice, which holds the green colouring part of the plant in solution, and which is the medium of union between its cortical and ligneous parts, undergoing a certain degree of putrefaction. This substance seems to resemble the glutinous part, which is held dissolved in the juice obtained from plants by pressure; is separated from the colouring particles by means of heat; readily becomes putrid; and by distillation affords ammonia. But although it is held in solution with the expressed juice, it would appear that it cannot be separated from the cortical parts completely by means of water; and hence it happens that hemp or flax watered in too strong a current has not the requisite softness and flexibility. But, on the other hand, if the water employed in this operation be stagnant and in a putrid state, the hemp or flax becomes of a brown colour, and loses its firmness. In the one case the putrefactive process is interrupted; in the other it is continued too long and carried too far. This process, therefore, is performed with the greatest advantage in places near the banks of rivers, where the water may be changed so frequently as to prevent such a degree of putrefaction as would be injurious to the flax, as well as prejudicial to the workmen, from noxious exhalations; and at the same time not so frequently as to retard or interrupt those changes which are necessary for rendering the glutinous substance soluble in water.

By the process of watering flax, and by drying before and after that process, the green-coloured particles undergo a similar change to that which is observed in the green substance of the plants exposed to the action of air and light. The next part of the process, therefore, after watering, is to spread it out upon the grass, and thus expose it for some time to the air and sun. By this means the colour of the lint is improved, and the ligneous part becomes so brittle that it is easily separated from the fibrous part. This operation, as is well known, is usually performed by machinery.

Mordants.

Structure. The fibres of lint possess no perceptible degree of elasticity, and they appear to be perfectly smooth. No roughness or inequality can be detected by the feel, and no asperities can be perceived, even with the assistance of the microscope. Experience shows, that it produces no irritation on wounds or sores which are dressed with it, as is known to happen from a similar application of cotton stuffs.

Preparations for dyeing. Flax which is intended for dyeing must be subjected to a similar series of operations with cotton, in the different processes of scouring, aluming, and galling. A repetition of the mode of performing these operations is therefore unnecessary.

CHAPTER III.

OF MORDANTS.

Meaning of the term. The term mordant is applied by dyers to certain substances with which the cloth to be dyed must be impregnated, otherwise the colouring matters would not adhere to the cloth, but would be removed by washing. Thus the red colour given to cotton by madder would not be fixed, unless the cloth were previously steeped in a solution of a salt of alumina. It has been ascertained that the cloth has the property of decomposing the salt of alumina, and of combining with and retaining a portion of alumina. The red colouring principle of the madder has an affinity for this alumina, and combines with it. The consequence is, that the alumina being firmly retained by the cloth, and the colouring matter by the alumina, the dye becomes fast, or cannot be removed by washing the cloth with water, even by the assistance of soap, though simple water is sufficient to remove the red colouring matter from the cloth, unless the alum mordant has been previously applied.

The term *mordant* (from the Latin word *mordere*, to bite) was applied to these substances by the French writers on dyeing, from a notion entertained by them that the action of the mordants was mechanical; that they were of a corrosive or biting nature, and served merely to open pores in the fibres of the cloth, into which the colouring matter might insinuate itself. And after the inaccuracy of this notion was discovered, and the real use of mordants ascertained, the term was still continued, as sufficiently appropriate, or rather as a proper name, without any allusion to its original signification.

Alterants. The term *mordant*, however, is not limited to those substances merely which serve, like alumina, to fix the colours. It is applied also to certain substances, which have the property of altering the shade of colour, or of brightening the colour, as it is called. Thus *cream of tartar* is usually called a mordant, because when chloride of tin is used, as is the case in the red dye upon silk or woollen, the addition of cream of tartar is necessary, not merely to brighten the colour, but to cause its equable application upon the cloth; for when the tartar is omitted, we observe that the shade is very unequal upon different parts of the surface, some spots being much darker and some much lighter than others. We believe that tartar acts chiefly, if not entirely, by forming a double salt with the chloride of tin, from which the tin is not liable to be partially precipitated. The consequence of this is, the equal distribution of the tin through the whole liquid, and the consequent equality of its application on the cloth. For the

Mordants. depth of the shade depends upon the proportion of tin fixed upon the cloth. Berthollet has proposed to distinguish those substances which are employed to alter the shade of colour from the mordants strictly so called, by giving them the name of *alterants*.

The mordants employed by dyers are but few in number. Alumina, the oxides of tin, the protoxide of lead, the black oxide of copper, and the infusion of nutgalls, constitute almost the whole of them. The peroxide of iron and the sesquioxide of manganese have also a strong affinity for cloth, especially for cotton cloth, and are frequently employed; but they serve at once the purpose of mordants and colouring matters. We believe also that in one important process for giving a fine red to cotton, what is usually called *the Turkey-red dye*, the *manganate of potash* constitutes an indispensable mordant.

Let us take a view of these different mordants in succession.

1. *Alumina.*—This is a soft, white, tasteless powder, insoluble in water, but soluble in acids, and constituting sweet-tasted and astringent salts, which have the property of reddening vegetable blues. These salts are soluble in water, but very few of them are capable of crystallizing. Of all the salts of alumina, the most important is *alum*, the nature and properties of which have been described in another part of this work. See ALUM.

How used. It is a double salt, composed of three integrant particles of sulphate of alumina united to one integrant particle of sulphate of potash or sulphate of ammonia and twenty-five integrant particles of water. The ammoniacal alum is less soluble in cold water than the potash alum; but both kinds are sufficiently soluble in hot water. Such is the affinity of alumina for woollen or silk stuffs, that when they are plunged into a solution of alum, the alumina leaves the sulphuric acid with which it was united, and combines with the fibres of the cloth. The affinity of alumina for cotton or linen, though considerable, is not so great as its affinity for wool or silk. On that account the cotton dyers and calico printers find it requisite to combine the alumina, before using it as a mordant, with a weaker acid than the sulphuric. The *acetic* is the one which has been made choice of, and the acetate of alumina is prepared by the following process: Three parts of alum and one part of acetate of lead are dissolved in eight parts of hot water. There is then added one eighth of a part of potash and as much chalk. The reason of the addition of the potash and the chalk is, that one part of acetate of lead is not sufficient to decompose three parts of alum. These substances prevent the residual alum from crystallizing, by decomposing it. The proper quantities of these salts which the dyers ought to employ are six parts of alum and seven parts of sugar of lead. These proportions would just convert the sulphate of alumina of the alum into acetate of alumina, without altering the sulphate of potash.

The wool or silk is put into a hot solution of alum, and the cotton into a hot solution of acetate of alumina, and passed through the liquid till a sufficient quantity of the alumina has combined with the fibres of the cloth. It is then wrung out, washed, and dried. The alumina remains firmly adhering to the cloth, and cannot be removed by washing, bleaching, or any of the processes to which such cloths are usually subjected.

Quantity of alumina which adheres to cotton. In order to form some notion of the quantity of alumina fixed upon cloth by the aluming process, the writer of this article made the following experiments: A quantity of cotton cloth was procured, such as is sometimes used for making light dresses of Turkey red. Of this, 1000 grains were burnt, and the ashes being reserved and analyzed, were found to contain 0·4 grain of alumina. 1000 grains of the same cloth which had been dyed Turkey red, and of course subjected to the aluming process, were burnt, and the ashes subjected to a chemical analysis. The alumina contained in them weighed eight grains. Hence 7·6 grains of this matter had combined with the cloth in the process of aluming.

The length of 1000 grains of the undyed cotton cloth was one yard five and two-third inches, and its breadth thirty-three inches. The length of 1000 grains of the Turkey red cloth was one yard and six inches, with a breadth of thirty-three inches. The two pieces of cloth, therefore, were very nearly of a size. We see that the dyed cloth had been stretched a very little during the processes to which it had been subjected. Thus it appears that a surface of cloth amounting to 1386 square inches, or rather 2772 square inches (as both sides of the cloth had been equally subjected to the aluming process), had combined with 7·6 grains of alumina, or every square inch of the cloth had combined with 0·0027 grains ($\frac{1}{370}$th grain nearly) of alumina. Small as this quantity may appear, it was sufficient to fix the red colouring principle of madder, and to constitute a very deep and beautiful dye.

A very pale shade of red is sometimes given to a portion of the cloth, which has a beautiful effect when contrasted with the deep Turkey-red dye. This is produced by limiting the quantity of alumina applied to the parts which are to be light red. In fact, no alum mordant whatever is applied to the parts which are to be light red; but they get a little during the steps taken to remove the excess of aluminous mordant, which has been applied to the parts that are to get the deep-red colour.

To ascertain the quantity of alumina which was sufficient to fix the light-red colour, the writer of this article got a portion of the same cotton cloth formerly operated on, dyed of the light-red colour. 1000 grains of this cloth being burnt, and the ashes analyzed, were found to contain 0·8 grain of alumina. Subtracting the 0·4 grain of alumina which 1000 grains of the undyed cloth contained, there remains 0·4 grain for the quantity communicated during the aluming process. These 1000 grains of cloth constituted a length of one yard and ten two-third inches. The breadth was thirty-two inches. Its surface (reckoning both sides) constituted 2986$\frac{2}{3}$ square inches. So that every square inch of surface had combined with 0·00012 grains of alumina, or less than $\frac{1}{8000}$th of a grain. Yet this quantity of alumina, small as it is, was essential to the permanence of the dye; for when unalumed cloth was dyed with madder, the colour was speedily and easily washed out by water; but the light-red Turkey-red dye was perfectly fixed.

These facts are sufficient to show us the very small size of a particle of alumina. Were only 1000 particles of this substance fixed upon the square inch of surface of cloth, the weight of a particle of alumina would not exceed the millionth part of a grain. But that the number far exceeds 1000 is evident from this, that when we examine the surface of the cloth with a microscope, the red colour does not appear in spots, but is equally spread over the whole cloth. Many thousand particles of alumina upon the square inch would be requisite to produce this effect.

The aluming and the dyeing are sometimes given to the cloth together; but more frequently the aluming precedes, and the dyeing follows after the cloth has imbibed the mordant and been washed and dried.

2. *Tin.*—Of all the metallic oxides, those of tin are the most useful as mordants. They form, with acids, salts very easily decomposed; and the fibres of cloth have an affinity so strong for these oxides, that they readily withdraw them from their saline combinations, and unite with them. Tin forms two different oxides with oxygen. The protoxide is *black*, but the peroxide is yellow, and sometimes also white.

Mordants.

The tin mordants are formed by dissolving tin in muriatic acid. There are two chlorides of tin, as the combinations of that metal with chlorine are called. These are, the protochloride and the perchloride. The protochloride, when anhydrous, is a gray solid, with a pearly lustre; but when it is formed by dissolving tin in muriatic acid, it crystallizes in large oblique four-sided prisms, with one edge usually replaced by a tangent plane. The colour is white, with somewhat of the diamond lustre. The taste is acid, acrid, and disagreeable. When recently formed they dissolve in water; but when kept they dissolve imperfectly, leaving a white matter behind, which is an oxide of tin, and the quantity of this insoluble oxide increases with the age of the crystals.

How prepared as a mordant.

Calico-printers form their tin mordant by dissolving tin directly in muriatic acid; but the silk and woollen cloth dyers employ aqua regia for the purpose. Indeed tin for the dyers was originally dissolved in weak nitric acid; but when this method is followed, almost the whole tin precipitates in the state of an oxide in a few days. To prevent this precipitation, they added a little common salt or sal ammoniac to the nitric acid in which the tin was to be dissolved. Hellot informs us that Baron claimed the merit of having been the first person who employed aqua regia at Carcassone to dissolve tin. The object in view was to prevent the precipitation of the oxide, which always happens when nitric acid alone is used for that purpose.

The dyer's ordinary solution of tin is made with the kind of nitric acid called single *aqua fortis*. It is capable of dissolving about the eighth part of its weight of granulated tin. For each pound of aqua fortis it is usual to add about two ounces of common salt or sal ammoniac, and a little water to moderate the action of the acid. Those solutions which have been made most slowly, and with the least separation of fumes or vapours, have been found to succeed best; showing clearly that it is the protochloride of tin that constitutes the proper mordant. Two ounces of grain tin are usually allotted to every pound of aqua fortis. The metal should be added at different times, waiting till one part is nearly dissolved before another is added, otherwise too much heat may be evolved, which would cause the solution to go on too rapidly. The quantity of water added should be about one half of that of the aqua fortis used; so that the solution, when completed, should contain about one thirteenth of its weight of tin. About 20 lbs. of such a solution is required to die 100 lbs. of woollen cloth a full cochineal scarlet.

The process usually followed is this: Supposing 100 pounds weight of cloths intended to be died; ten pounds of cream of tartar are put into a suitable dyeing vessel of pure block tin,[1] with a sufficient quantity of clean soft water, and six or eight ounces of powdered cochineal. Immediately after this, ten or twelve pounds of the solution of tin are to be added, and when the mixture is nearly boiling hot, the cloth, previously completely wet, is put into the dyeing liquor, and turned through it by the winch, at first very rapidly, and afterwards slowly. This is to be continued for an hour and a half, after which the cloth is to be taken out and rinsed in clean water. By this first process the cloth has acquired a flesh colour. For the second or dyeing process the tin vessel is replenished with clean water. Five or six pounds of cochineal in powder are to be put into it, and well mixed by stirring it for a few minutes. After this the remaining part of the solution of tin is to be added; and the whole being well stirred, the cloth is to be put into the liquor, and turned very briskly through it, that both ends may receive an equal portion of the dye. After this it is turned more slowly for the space of half an hour, or until the dyeing liquor becomes exhausted, when the cloth is to be taken out, aired, and rinsed.

The process followed by the calico-printers for preparing the tin mordant is to dissolve tin in muriatic acid, by which a protochloride of tin is obtained. But Dr Bancroft found that, when a saturated solution of tin in muriatic acid was employed for dyeing woollen cloth scarlet, it had a corrosive effect on the cloth. He recommends a mixture of nitric and muriatic acid as a good solvent; and doubtless such a mixture would be cheaper and better than a solution of common salt or sal-ammoniac in nitric acid. Dr Bancroft found that a mixture of sulphuric and muriatic acid made a good solvent for the tin. Some farther experiments are still wanting to elucidate the best state of the tin mordant for the scarlet dye. We are of opinion that it is the protochloride of tin that constitutes the true mordant;[2] but some addition seems necessary to enable the fibres of the cloth to separate the oxide of the tin from the combination in which it exists, or rather to unite with the muriatic acid, when it is formed and disengaged by the decomposition of water, which obviously takes place, otherwise this acid, when evolved, will exert a corrosive action on the cloth.

The tartar is necessary to produce the scarlet colour. Without it the colour of the cochineal dye is crimson, or at most a rose colour. It doubtless acts principally by forming a double salt with the chloride of tin. But it must also convert a portion of the cochineal into a yellow dye; for scarlet is a compound colour, consisting of a great deal of red, mixed with a small quantity of yellow.

Used to fix chromic acid.

3. *Lead.*—We are not aware of the protoxide of lead being employed in any case as a mordant in dyeing silks or woollen cloth; but of late years it has been used as a mordant for cotton, to which the beautiful yellow given by means of chromic acid was to be communicated. For this purpose the lead is dissolved in nitric acid, or converted into nitrate of lead. This salt crystallizes in octahedrons, has a sweet and astringent taste, and dissolves readily in water. An aqueous solution of it thickened by gum is applied to those parts of the cloth which are to receive a yellow colour; or if the cloth has been already dyed red, a quantity of tartaric acid is mixed with the solution of nitrate of lead and gum, and after it has been applied and dried on the cloth, the piece is passed through water impregnated with a quantity of bleaching powder. The red colour is discharged; but the oxide of lead, which had united with the fibres of the cloth, still continues to adhere without alteration. The cloth is now passed through a solution of bichromate of potash. Those parts of it which contained the oxide of lead immediately decompose the bichromate; chromate of lead is formed and fixed upon the cloth, constituting a most beautiful and indelible yellow colour; or, by particular alterations in the process, this yellow colour may be changed to red, or to a very deep orange approaching red, and exceedingly beautiful.

4. *Copper.*—The black oxide of copper is employed as a mordant in giving a black colour to hats, or at least acetate of copper is employed in the process; and it is not easy to conceive any other purpose which such a salt can serve than contributing a portion of oxide of copper to act as a mordant.

5. *Galls.*—Nutgalls are excrescences which grow on

[1] Copper vessels are found to injure the colour, and therefore are not used.

[2] We do not mean that the protoxide of tin remains fixed on the cloth: it doubtless becomes peroxide. But the superior solubility of protochloride of tin fits it better for the purpose.

Mordants. Excrescences on oak.

the branches of some species of oak, in consequence of the puncture of an insect, the *cynips quercus folii*. The best kind come from the Levant. They are nearly spherical bodies, with protuberances on the surface. There is a cavity within where the insect lodged, and a round hole from that central cavity to the surface, by which the insect, after it was hatched from the deposited egg, eat its way out. These nutgalls have a very astringent and austere taste. When digested in water they give that liquid a brown colour, and the taste which they themselves have. When such an infusion is mixed with a solution of sulphate of iron, it strikes a deep blue or black colour. Nutgalls, besides a considerable portion of woody fibre, contain a notable quantity of two peculiar vegetable substances, to which they owe their value as dyestuffs or mordants. These are *tannin* and *gallic acid*. The latter of these substances is easily obtained in a state of purity; the former with difficulty.

Contains tannin.

The infusion of nutgalls contains scarcely any thing else than a solution of tannin and gallic acid. If we evaporate the solution in a gentle heat to dryness, and digest the residue in sulphuric ether or absolute alcohol, the gallic acid will be dissolved, and the tannin will remain in a state of tolerable purity, only coloured brown by the action of the air. Tannin, when pure, is white while moist. It becomes yellow when dried even *in vacuo*, and by subsequent exposure to the air it becomes darker coloured. Its taste is excessively astringent and harsh; and it is distinguished by the property of striking a deep blue or black with the salts of iron. Tannin is easily altered in its nature by heat. Its constitution, as determined by the most recent analyses, is,

$$\left.\begin{array}{ll} \text{Carbon} \ldots\ldots\ldots\ldots & 18 \text{ atoms} \\ \text{Hydrogen} \ldots\ldots\ldots & 5 \text{ atoms} \\ \text{Oxygen} \ldots\ldots\ldots\ldots & 9 \text{ atoms} \\ \quad\text{united with} & \\ \text{Water} \ldots\ldots\ldots\ldots & 3 \text{ atoms} \end{array}\right\} C_{18}\,H_5\,O_9 + 3\,HO.$$

Many modifications of it are found throughout the vegetable kingdom, all characterised by a harsh, astringent taste, and the property of giving a black, dark-blue, or brown colour with salts of iron, so that various shades of these colours can be produced by selecting the tannin of different plants, and employing it in dyeing along with copperas or other ferruginous compounds.

Distinctive names have been given to the varieties of tannin by scientific chemists, who rank them all among vegetable acids, of which, however, they form an imperfectly defined group; their general insusceptibility of crystallization preventing their ready purification, and their liability to undergo chemical changes on exposure to air interfering with their preparation in a state of purity. The tannin of the oak and its gall-nuts, which alone is referred to in what follows, has been distinguished by the name of *quercitannic acid.*

Tannin exists not merely in nutgalls, but in oak bark, in the wood of the oak, in the leaves, and in fact in every part of that tree; but the quantity of it is much greater in nutgalls than in any other part.

Tannin possesses the characters of an acid. It reddens vegetable blues, effervesces with the carbonates, and unites in definite proportions with the basis.

and gallic acid.

Gallic acid exists also as a constituent of nutgalls, and may be extracted from them by means of ether or absolute alcohol. Its colour is white, though it is apt, like tannin, to become yellow when exposed to the atmosphere, and seems indeed capable of being converted into tannin by exposure to too high a temperature. It is not nearly so soluble in water as tannin, and is distinguished by an acid taste instead of an astringent one. Like tannin, it strikes a black with the salts of iron. But the gallate of iron is readily distinguished from the tannate. The former is an exceedingly fine black powder, which precipitates very slowly, while the latter is a deep blue, which precipitates rapidly, has a coarse appearance, and becomes black when dry. The constituents of gallic acid are,

$$\left.\begin{array}{ll} \text{Carbon} \ldots\ldots\ldots\ldots & 14 \text{ atoms} \\ \text{Hydrogen} \ldots\ldots\ldots & 5 \text{ atoms} \\ \text{Oxygen} \ldots\ldots\ldots\ldots & 9 \text{ atoms} \\ \quad\text{united with} & \\ \text{Water} \ldots\ldots\ldots\ldots & 1 \text{ atom} \end{array}\right\} \text{or } C_{14}\,H_5\,O_9,\ HO.$$

Gallic acid has recently been prepared in considerable quantity and of great purity by the pharmaceutical chemists of this country and the Continent, who can now furnish it beautifully crystallized. In the state of crystals it is employed by medical men as a valuable internal remedy in several disorders. It is turned to some account also by the photogenic artist; and analytical chemists prepare from it another and allied acid called the *pyrogallic*, which is highly serviceable in effecting the analysis of air. The dyer, however, uses it uncrystallized.

How used as a mordant.

The great use to which the infusion of nutgalls is put in dyeing is to give a black colour when mixed with solution of sulphate of iron. When used in this way it perhaps is improperly named a mordant; for the oxide of iron is known to have a strong affinity for the fibres of cloth, and the tannin and gallic acid have a strong affinity for the oxide. Hence probably the way in which the black dye is fixed on silk and woollen cloth. There can be no doubt that the tannin, which is by far the most abundant ingredient, is the principal agent in striking the black with the sulphate of iron. But the gallic acid probably adds to the lustre, and improves the beauty of the colour.

In the Turkey-red process for giving a fixed red colour to cotton cloth by means of madder, steeping the cloth in infusion of nutgalls is an important part of the process, as without this the colour would be apt to want equality of shade in different parts of the cloth. In this process there can be no doubt that tannin acts the part of a mordant. The galling, in preparing the cloth for the Turkey-red dye, always precedes the alumina process. Whether it has the property of making the alumina more fixed on the cloth than it otherwise would be, or what other purpose it may serve, is not very well understood; but it is certain that the boiling of the cloth in a pretty strong infusion of galls is important. The infusion of galls is made by boiling twenty-five pounds of nutgalls in forty gallons of water, till four or five gallons are boiled or evaporated. The specific gravity of the infusion is 1·020; or sometimes the process is twice repeated, employing each time only twelve and a half pounds of nutgalls in forty gallons of water. The specific gravity of each infusion in that case is only 1·010.

Such is an account of the mordants at present employed in dyeing, and the way of using them. It is not always necessary to employ mordants in dyeing; some colouring matters adhere to the cloth without the presence of any intermediate substance. This is the case with the oxides of iron and manganese. It is the case also with indigo, and it was the case also with the colouring matter from the buccinum and purpura employed by the ancient Phœnician dyers in dyeing the celebrated purple, of which an account has been given in the first chapter of this treatise. To those colouring matters which adhere to the cloth of themselves Bancroft has given the name of *substantive* colours, while he distinguishes those that require a mordant by the name of adjective colours.

Mordants.

Effects of mordants on the colour

Mordants have a very considerable effect on the colour; and by varying the mordant, very different colours, and a great variety of shades, may be obtained from the same colouring matter. Some mordants themselves may be considered as communicating a colour, without the addition of any colouring substance; and although, when the latter is added, a new set of affinities is brought into action, yet there is little doubt that the mordant also has a considerable share in fixing the shades of colour. Let us take an example in dyeing with cochineal. When the aluminous mordant is employed, the colour produced is crimson; but when the oxide of iron is substituted for the alumina, the colour obtained is black. The effect is obviously produced by a change in the action of the affinities between the colouring matter and the mordant, and the colouring matter and light. In the use of mordants, therefore, it is necessary to attend to their combined effects with the colouring matter employed, and, to be able to communicate particular colours to stuffs with any degree of certainty, to know the amount of that effect.

Even in the mode of applying mordants, the variety of shades may be greatly multiplied. Different effects, for instance, are produced by previously impregnating the stuff with the mordant, or by mixing it with the bath. Different effects also arise from using heat, or as the stuff is more or less rapidly dried; and this must appear to be the case, if we consider the different affinities which are in action, and the change on the action of these affinities in these different circumstances, as well as in others which can scarcely be appreciated. The combination of these substances which have an affinity for the stuff, and the decompositions which are the result of that combination, are greatly facilitated by the evaporation of the water or other liquid which held these substances in solution; because by its affinity, which is opposed to the action of the affinity between these substances and the stuff, the affinity of the latter produces a more limited effect. But in dyeing, the process should proceed slowly, that the substances may not be separated before their mutual affinities have begun to operate.

Considerable differences must be observed in the mode of employing the mordant, as the force of affinity between the stuff and the colouring matter is greater or less. When this affinity is strong, the mordant and the colouring substance may be mixed together; the compound thus formed immediately enters into combination with the stuff. But if the affinity between the stuff and the colouring particles be weak, the compound formed of the latter and the mordant may separate, and a precipitation take place, before it can be attached to the stuff; and hence it is in these cases that the mordant, which is to serve as the medium of union between the stuff and the colouring matter, must be combined with the former, before the application of the latter. It is from these differences that different processes must be followed in fixing colouring matters on animal and vegetable productions; as, for instance, in dyeing wool or silk black, or with cochineal.

In estimating the effects of mordants, and in judging of the most advantageous manner of applying them, it is necessary to attend to the combinations which may be formed, either by the action of the ingredients of which they are composed, or by that of the colouring matter and the stuff. It is necessary also to take into consideration the circumstances which may tend to bring about these combinations with more or less rapidity, or that may render them more or less perfect. The action which the liquor in which the stuff is immersed may have, either on its colour or texture, must also be considered; and, to be able accurately to judge of the extent of this action, we must know the proportions of the principles of which the mordant is composed; which of these principles remains in an uncombined state in the liquor; and the proportion or quantity which is thus separated.

Simple Colours.

CHAPTER IV.

OF THE MODE OF DYEING SIMPLE COLOURS.

Dyers have divided colours into two classes, namely, *simple* and *compound* colours. The *simple* are produced by a single dyeing process, and cannot be obtained by mixing together different colours. The compound colours are obtained by mixing together any two of the dyestuffs which produce the simple colours. By this means two colours are given to the cloth at once; and the shade depends upon the proportions of each dyestuff employed.

The simple colours are five in number; namely, *red*, *yellow*, *blue*, *black*, and *brown*. The last of these may be considered also as a compound colour, as it may be formed by mixing the dyestuffs for two simple colours together. The compound colours are *orange*, *green*, *purple*, and *gray*. We shall in this chapter confine ourselves to the mode of dyeing the simple colours, dividing it into five sections, in each of which we shall treat of a simple colour.

SECT. I.—*Of Red.*

In treating of the red dye, the simplest method seems to be to give an account, in the first place, of the dyestuffs employed for dyeing red; and in the second place, to describe the methods followed by the dyer to give a red colour to silk, wool, cotton, and flax.

I.—*Description of the Dyestuffs.*

The principal colouring matters used in dyeing red are *madder*, *cochineal*, *kermes*, *lac*, *archil*, *carthamus*, *Brazil wood*, and *logwood*.

1. *Madder* is the root of a plant, the *rubia tinctorum*, which is cultivated in the south of Europe. There are two varieties, the *rubia cordifolia* and the *rubia peregrina*. It is this last which is cultivated in the south of Europe, and comes to us from the Levant. The roots are wiry, and very much branched. They have a red colour externally, but are yellow within. This plant was cultivated by the Greeks and Romans, and was employed in medicine, and also in dyeing, as Dioscorides and Pliny inform us. It was called *erythrodamus* and *vœrantia* by the Greeks, and *rubia* by the Romans. From the last Greek name is derived the French word *garance*, by which madder is distinguished in that language.

Contains two colouring matters

It is the woody portion of madder that is useful in dyeing: the bark and pith are comparatively of little value. Madder has been examined by many chemists; but Robiquet and Colin alone have succeeded in separating the red colouring matter, and in determining its properties. They have distinguished it by the name of *alizarin*, an appellation derived from *alizari*, by which madder is distinguished in the Levant.

Madder contains two colouring matters; one, which is yellow, is soluble in cold water; the other, the alizarin, is soluble only in boiling water. To the yellow colouring matter Kuhlmann has given the name of *xanthin*. This matter considerably injures the colour of the alizarin; hence the reason why cloth dyed with madder has at first a dull brownish-red colour, which it loses in proportion as the xanthin is removed.

Alizarin how obtained.

To obtain *alizarin*, Robiquet and Colin recommend the following process. Mix pounded madder with two thirds or with its own weight of concentrated sulphuric acid, and

Simple Colours.

set the mixture aside for two or three days, taking care that heat is not evolved. All the other constituents of the madder, except the alizarin, are converted into charcoal; and should heat have been evolved, even the alizarin itself will be charred. Wash the black matter thus formed, to extract from it all the acid. What remains is a mixture of charcoal and alizarin. Let it be dried and digested with a portion of cold alcohol, which will dissolve a fatty matter which it contains. Let it now be digested in boiling alcohol till all the alizarin is dissolved. Mix the alcoholic solutions with water, distil off the alcohol, and filter the residual liquor. The alizarin remains upon the filter in a state of purity. Various other processes for extracting alizarin have been given by Robiquet and Colin, and by Kuhlmann and Zenneck.[1] But for these we refer to the respective publications of these chemists. The process which we have given we consider as of easiest execution.

Its properties.

Alizarin is insipid, and destitute of smell. According to Zenneck, it possesses weakly acid properties; but Colin and Robiquet consider it as perfectly neutral. It sublimes easily in long flexible capillary needles, having an orange colour; but unless the subliming vessels be very low and flat, much of the alizarin is decomposed during the process. Two watch-glasses applied to each other, for example, answer very well as a subliming vessel. During the process the alizarin gives out an aromatic odour like that of benzoin. It is almost insoluble in cold water; but it is moderately soluble in boiling water, to which it communicates a rose-red colour. At the temperature of 54°, 212 parts of alcohol, of the specific gravity 0·83, dissolve one part of alizarin. At the same temperature sulphuric ether, of specific gravity 0·73, dissolves $\frac{1}{160}$th part of its weight of it. The alcoholic solution is red, that of ether yellow or orange. It is slightly soluble in bisulphide of carbon, oil of turpentine, naphtha, and the fat oils, communicating to these bodies a reddish-yellow colour. Chlorine has little action on it, yet it injures the colour a little, and makes it incline to yellow. Sulphuric acid dissolves it, and acquires at the same time a blood-red colour. Nitric and muriatic acid dissolve it, and slightly alter the shade of its colour. These acids, when dilute, do not dissolve it. With alkalies it forms soluble combinations, having a violet-red colour, which do not afford crystals. The alkaline carbonates dissolve it, assuming a violet colour. With the alkaline earths it forms precipitates, having a violet or lilac colour; with alumina a precipitate which is red or reddish-brown. With the metallic oxides it forms insoluble combinations, having a violet or reddish-brown colour.

It has a marked affinity for various animal matters. It dissolves in the white of an egg diluted with water; and if we coagulate the albumen by heat, the alizarin combines with it, leaving the liquid portion tinged yellow. Albumen, containing a portion of alizarin in solution, is precipitated by a solution of chloride of calcium; yet this salt does not precipitate uncombined albumen diluted with the same quantity of water. Phosphate of lime appears also to have a marked affinity for the colouring matter of madder. Indeed this is obvious, from the well-known fact, that the bones of animals which have taken for some time a quantity of madder mixed with their food, are tinged red.

Urine, when left in contact with madder, extracts from it the alizarin, and acquires a red colour, even when quite recent and acid. Milk is coloured yellow by madder, and red coagulated curd is deposited upon the madder. The solution of animal gelatin does not precipitate the red colouring matter of madder.

Simple Colours.

We are not aware that madder is employed in dyeing silk or wool, but it constitutes one of the most beautiful and fixed red dyes for cotton and linen, and for dyeing these substances it has been in use probably at least two thousand years. As the yellow colouring matter or *xanthin* is not used in dyeing, it seems unnecessary to give any account of it in this place.[2] It gives a very beautiful yellow colour, and might be employed in calico-printing, were it not that the extraction of it would cost too much money.

Nature of cochineal.

2. *Cochineal* is the name given to a small insect that inhabits the *cactus coccinilifera*, and three or four other species of cactus, upon which it remains immoveable, drawing its nourishment from the juices of the plant. The insect is called by entomologists *coccus cacti*. It is the female insect (which is without wings) that constitutes the dyestuff. The insect is small, having a kind of hemispherical back, crossed by numerous wrinkles, and of a dark reddish-brown colour.

This insect is a native of Mexico, and had been employed by the natives as a red tinging matter. When the Spaniards entered that country in 1518 it drew their attention; and in 1523 Cortes received orders from the court of Spain to procure it in as great quantity as possible. He left the cultivation of the insect to the natives, who prosecuted it so successfully that great quantities of it were imported into Europe. The earlier Spanish writers described it as an insect, but at a later period it came to be considered as the seed of a plant; and this opinion continued the prevalent one, till the contrary was proved by Melchior de Ruuscher, about the beginning of the eighteenth century. This man, who was a native of Holland, affirmed in a society, from oral information which he had obtained in Spain, that cochineal was a small animal. Another person, whose name has not been made known, maintained the contrary with so much heat and violence, that the dispute at length ended in a bet. Ruuscher charged a Spaniard, one of his friends, who was going to Mexico, to procure for him in that country authentic proofs of what he had asserted. These proofs, legally confirmed in October 1725, by the court of justice in the city of Antiguera, in the valley of Oaxaca, arrived at Amsterdam in the autumn of the year 1726. Ruuscher caused this evidence to be published under the following title: *The History of Cochineal proved by authentic documents*.[3]

The fact that cochineal is an insect had been suspected before. In a very crude and unsatisfactory paper on cochineal, published in the *Philosophical Transactions for* 1668,[4] this is distinctly stated as an undoubted fact. In 1672 Dr Lister, in a paper inserted also in the *Transactions*, throws out a conjecture that the cochineal insect may be a sort of kermes; which conjecture is now known to be well founded. Leeuwenhoeck is said to have examined cochineal microscopically in 1703, and to have ascertained it to be an insect. About the beginning of the year 1757 Mr Ellis obtained some of the joints of the plant on which the

Simple Colours.

insects breed, from South Carolina, and presented them the same year to the Royal Society. These specimens, Mr Ellis observes, were full of the nests of this insect, in which it appeared in its various states, in the most minute, when it walks about, to the state when it becomes fixed, and wrapt up in a fine web which it spins about itself. With the assistance of the microscope, Mr Ellis discovered the true male insect in the parcels which had been sent to him from America; and in August 1756, in consequence of Mr Ellis's discovery, Dr Garden caught a male cochineal fly, which, he observes, is rarely to be met with. He supposes that there may be 150 or 200 females for one male. These discoveries proved indisputably that the cochineal is an animal production.

Cochineal has been subjected to a chemical examination by various individuals; but the most successful analysis of it is by Pelletier and Caventou in 1818, which was published in the eighth volume of the *Annales de Chimie et de Physique*, p. 250. They found it to contain about half its weight of the peculiar colouring matter to which they applied the name *carmine;* but we prefer the name cochinealin, already given to this substance by John, who was the person that first obtained it and described its properties. Cochinealin may be obtained by the following process:—

Contains cochinealin.

Digest cochineal in alcohol, as long as it communicates a red colour to that liquid. The alcoholic solution being left to spontaneous evaporation, lets fall a crystalline matter of a fine red colour. Dissolve these crystals in strong alcohol, and mix the solution with its own bulk of sulphuric ether. The liquid becomes muddy, and gradually deposites the cochinealin, which constitutes a purple crust on the bottom of the vessel.

Properties of cochinealin.

Cochinealin has a fine purple-red colour, is granular, and consists of small crystals. When left exposed to the air, it undergoes no sensible alteration. At 122 degrees it melts; and if the heat be increased, it swells up and is decomposed, yielding carburetted hydrogen gas, a great deal of oil, and a little water having a slightly acid taste. It furnishes no traces of ammonia.

It is very soluble in water. The aqueous solution has a fine carmine colour, and, how much soever concentrated, does not deposite crystals. It dissolves also in alcohol; but the solubility diminishes in proportion to the strength of the alcohol. In sulphuric ether it does not dissolve. The weak acids dissolve it, probably in consequence of the water which they contain. When the cochinealin is pure, no acid throws it down from its aqueous solution; but they precipitate it when in combination with the peculiar animal matter of cochineal. They produce a sensible change upon its colour, causing it gradually to assume a tint of yellow. This is the reason why cochineal will not dye scarlet, unless when mixed with bitartrate of potash. The concentrated acids decompose it altogether.

Alkalies also alter the colour of solutions of cochinealin. It first becomes violet, and at last yellow; and the original colour cannot be again restored. Lime-water occasions a precipitate when poured into an aqueous solution of this substance; but barytes and strontian water occasion no precipitate, though they change the colour to yellow. Alumina has a strong affinity for cochinealin. When newly precipitated alumina is agitated in an aqueous solution of it, the liquid is rendered colourless, and the alumina converted into a beautiful *lake*. The pigment called *carmine*, accidentally discovered by a Franciscan monk about the middle of the sixteenth century, and the process for obtaining which was published by Homberg in 1656, consists essentially of a combination of cochinealin and alumina.

Simple Colours.

Most of the saline solutions alter the colour of the aqueous solution of this substance; but few of them are capable of producing a precipitate in it. Acetate of lead, however, throws down a copious violet sediment from the decoction or infusion of cochineal; and by decomposing this sediment by means of sulphuretted hydrogen, the cochinealin may be obtained in a state of purity. The chloride of tin throws down a violet precipitate, and the perchloride strikes a fine scarlet colour, but precipitates nothing. When gelatinous alumina is added to this mixture, we obtain a fine red precipitate, which is not altered by boiling.

Cochineal was at one time used in great quantity in Europe, chiefly for dyeing fine scarlet cloth. When Bancroft published his work on colours in 1794, he informs us that the annual European consumption was about 3000 bags, or 600,000 lbs., of which about 240,000 lbs. were consumed in Great Britain. The demand has since that time very much diminished; and the price has in consequence sunk from about thirty shillings to about nine shillings and sixpence per pound. This diminution is chiefly owing to the substitution of the lac dye for cochineal. Cochineal, however, is still used for the dyeing of fine scarlet cloth.

3. *Kermes.*—This is also the female of an insect which inhabits a species of oak. The tree, which is a native of the countries bordering on the Mediterranean and Asia, is called by Linnæus *quercus ilicis*, and the insect *coccus ilicis*. This substance was known to the ancients, though they were ignorant of its nature. Dioscorides calls it *κοκκος*, and Pliny *coccum* and *granum*. It was used in medicine; and there can be no doubt that it was employed in Asia at a very early period as a dyestuff. There is reason to suspect that the *scarlet* cloth mentioned by Moses to adorn the tabernacle was dyed by means of kermes. If this conjecture has any foundation, the kermes dye must have been known in Egypt before the time of Moses.

Similar to cochineal.

The word *kermes* or *alkermes* is at present in the East the common name for the animal which produces the dye, as well as for the dye itself. Probably it comes from the Arabic. If the kermes dye was known in Egypt and Phœnicia in the time of Moses, there is some difficulty in explaining how it was altogether unknown to the Greeks and Romans till the time of the Emperor Aurelian, who began his short reign in the year 270 of the Christian era. Vopiscus informs us that the king of Persia sent to that emperor, besides other articles of great value, some woollen cloth, which was of a much costlier and brighter purple than any that had been ever seen in the Roman empire, and in comparison of which all the other purple worn by the emperor and the ladies of the court appeared dull and faded. Vopiscus goes on to say that this cloth had been dyed in India, and that the assertion of the king of Persia, *sume purpuram qualis apud nos est*, was false; for Aurelian, Probus, and Diocletian, had sent dyers into the East on purpose to get information respecting this precious dye; but that their attempts utterly failed of success.[1]

From this passage it would appear that the use of kermes in dyeing had been known at a very early period in India, from which it gradually made its way into Persia, and afterwards into Europe. And as the colour which it yielded was more beautiful than the celebrated Phœnician dye, it may have contributed to put an end to the monopoly of the Phœnician dyers. The term *scarlet*, the

[1] Vopiscus in *Vita Aureliani*, cap. 29.

Simple Colours.

origin of which is unknown, but which was certainly employed early in the twelfth century, was applied to the colour given to cloth by the kermes dye.

Kermes is gathered chiefly in Languedoc, Spain, and Portugal. The insects are collected in the months of May and June, when the female, which alone is useful, is distended with eggs. To destroy the young insects, the kermes is exposed to the steam of vinegar for about half an hour, and afterwards dried. It is in the form of small grains of a reddish-brown colour. Kermes, as appears from the experiments of Lassaigne,[1] contains the very same colouring matter as cochineal; but its quantity is not so great, and of course it is mixed with a greater proportion of animal matter. The introduction of cochineal greatly diminished the consumption of kermes. It is seldom used in this country, yet it gives a very fixed and beautiful colour to woollen cloth.

Also similar to cochineal.

4. *Lac.*—This is an animal production which has been long known in India, and used for dyeing silk and other purposes. It is the *nidus* of the *coccus lacca*, Linnæus, and is generally produced on the small branches of the *croton lacciferum*. Three kinds of lac are well known in commerce:—1. Stick lac is the substance or comb, in its natural state, forming a crust on the small branches or twigs. 2. Seed lac is said to be only the above separated from the twigs and reduced into small fragments. Mr Hatchett, who has examined this substance with his usual skill and precision, found the best specimens considerably deprived of their colouring matter.[2] According to the information which he received from Mr Wilkins, the silk dyers in Bengal produce the seed lac by pounding crude lac into small fragments, and extracting part of the colouring matter by boiling. 3. Shell lac is prepared from the cells, liquefied, strained, and formed into thin transparent laminæ. There is also a fourth kind, called *lump lac*, which is obtained from the seed lac by liquefaction, and afterwards formed into cakes. The best lac is of a deep red colour: when it is pale and pierced at the top, the value is greatly diminished; for then the insects have left their cells, and it can no longer be of use as a dyestuff.

Unverdorben has likewise examined lac, but his experiments throw no light upon the nature of the colouring matter. Being derived from a coccus, as well as the colouring matter of cochineal and kermes, the probability is that it is of the same nature. In the state in which it comes to this country (that of a purple powder), it dissolves readily in boiling hot water. In this way it is employed by the dyers. Being much cheaper than either cochineal or kermes, it has in some measure superseded these dyestuffs, except when a very fine scarlet is wanted, in which case cochineal is still employed.

5. *Archil.*—This substance, called *orseille* by the French, is a violet-red paste, of which there are two varieties, one, which is the best, made in the Canary Islands, the other manufactured in the south of France. It is made from two species of lichens, the roccella and the parellus. Berthollet, who has copied Hellot, who again copied Micheli, has given the following description of the mode of preparing it. The plant is reduced to a fine powder, which is afterwards passed through a sieve, and slightly moistened with stale urine. The mixture is daily stirred, each time adding a certain proportion of soda in powder, till it acquire a clove colour. It is then put into a wooden cask, and urine, lime-water, or a solution of sulphate of lime (*gypsum*), is added in sufficient quantity to cover the mixture. In this state it is kept; but to preserve it any length of time, it is necessary to moisten it occasionally with urine. We suspect that soda is not employed in the preparation of this dyestuff; at least it is not employed in the manufacture of cudbear, the preparation of which, being a manufacture of this country, we have often witnessed.

How prepared.

If we adopt the opinion of Tournefort, the preparation of archil was known to the ancient Greeks. He thinks that the purple of Amorgos, one of the Cyclades, the colour given to the famous tunics of that country, was formed by a dyestuff made from the lichen roccella.[3]

Cudbear how prepared.

What is called in this country *cudbear*, and in Germany *persio*, is prepared from the lichen *tartareus*, and *omphalodes*, by a process quite similar to that employed for making archil. The lichen is steeped and left for some time in flat vessels moistened with ammonia distilled from putrid urine. When the purple colour is sufficiently developed, the whole is dried in the open air, and reduced to a fine powder. The manufacture of this dyestuff was begun about the year 1777, at Leith, by Mr Mackintosh and Dr Cuthbert Gordon, from which last the British name of *cudbear* (originally *Cuthbert*) is derived. Leith was found an improper place for the manufacture; but Mr Mackintosh transferred it to Glasgow, and manufactured cudbear during the rest of his life with success. He left it to his son Charles Mackintosh, Esq., who continued the manufacture. The lichens used were at first collected in the Highlands of Scotland; but the rocks of that country being stript of their covering, the manufacturers had recourse to Sweden and Norway, and likewise to Sardinia, from which countries prodigious quantities of the lichens were brought. Cudbear is now prepared largely in England, and lichens are imported from all parts of the world.

Neither archil nor cudbear are capable of giving fast colours to cloth; but they are considered as indispensable by the dyers, because they greatly improve the brilliancy of some of the colours.

Contains erythrin.

The nature of the substance in the lichen roccella, which furnishes the colouring matter of archil, has been investigated by Heeren, who has distinguished it by the name of *erythrin*. It may be obtained from the lichen by the following process: Digest the lichen for some time in alcohol, taking care not to raise the heat to the boiling point, because at that temperature a portion of the erythrin is decomposed. The alcoholic solution has a green colour. Filter it while hot, and mix it with twice its bulk of water, which will render it muddy. Raise the liquid to the boiling temperature, and introduce into it chalk in powder, until the precipitate, which was at first dispersed through the liquor, collects in flocks. This precipitate consists chiefly of *roccellate of lime*.[4] The liquid must be filtered while boiling hot. During the cooling it deposites erythrin in the state of a fine powder, of a brown colour. Dissolve it in hot alcohol, digest the solution with ivory black, filter, and mix it with one and a half times its bulk of boiling water. The liquor remains at first clear, but during the cooling the erythrin precipitates nearly white.

The following process for extracting erythrin from the lichen roccella is easier than the preceding. Pour on the lichen a small quantity of concentrated ammonia, and digest for some time, stirring well, but without the application of heat. Dilute the muddy and reddish solution thus obtained with water; and then add to it some dilute solution of chloride of calcium. Roccellate of lime precipitates, and the filtered liquid has a reddish colour. Add to it a slight excess of muriatic acid. The erythrin precipitates instantly, and gives the liquid the aspect of a yellowish jelly. When we

[4] Roccellic acid is an acid discovered by Heeren in the lichen roccella.

Simple Colours.

heat to the boiling temperature, the erythrin is again dissolved, and it is precipitated in powder during the cooling of the liquid. It may be deprived of its brown colour by ivory black.

Its properties.

Erythrin is a soft powder, having usually a slight shade of red, and a slightly crystalline aspect, when obtained from a weakly acid liquid. When pure it is perfectly white. It has neither taste nor smell. At a temperature a little above 212°, it melts into a transparent liquid, which becomes hard and brittle during the cooling. If the heat be raised still higher, it froths, is partly volatilized, and partly charred; but not the least trace of ammonia can be observed to be formed. Hence we may conclude that erythrin contains no azote. When held to the flame of a candle it burns like a resin. It is scarcely soluble in cold water, and requires 170 times its weight of boiling water to dissolve it. At the temperature of 53° it dissolves in twenty-two and a half times its weight of alcohol, of specific gravity 0·825. It is soluble in 2·29 times its weight of the same alcohol at the point of ebullition. When this last solution cools, the whole is converted into a mass of the consistence of mortar. It is insoluble in ether, and little soluble in oil of turpentine. Muriatic acid has no action on it, but acetic acid dissolves it with facility when boiling hot, but lets it fall again on cooling. Both nitric acid and concentrated sulphuric acid dissolve it, but they alter its nature. The aqueous solutions of the alkalies, or their carbonates, dissolve it with facility, and the solutions are colourless. By the continued action of the alkalies, the erythrin is decomposed. When this action takes place in close vessels, an extractive substance is formed, which is soluble in water, having a bitter taste, and which Heeren on that account has called *bitter of erythrin.* When the action is continued in vessels to which the air has access, the red or rather violet substance is formed which constitutes the colouring matter of archil.

During the conversion of erythrin into the red matter three different substances are obtained, namely, the *red colouring* matter, a *yellow* substance, and a *wine-red* substance. They are first mixed or combined; but the red colouring matter may be separated by dissolving the compound substance in alcohol, evaporating the solution to dryness, and digesting the residue in ammonia. The red colouring matter remains when this solution is evaporated.

It is little soluble in water. Alcohol dissolves it, and the solution has a crimson-red colour. It is quite insoluble in ether. The alkalies and their carbonates dissolve it, and the solution has a fine deep colour. The acids throw it down from these solutions under the form of carmine red powder, but they do not precipitate it from its solution in alcohol. Heeren has shown that alcohol has the property of altering erythrin, and of converting it into a snow-white substance, to which he has given the name of *pseudo-erythrin,* because it does not yield the red colouring matter, but only the wine red. The colouring matters of the lichens have, however, been very recently made the subject of extensive chemical investigation by Kane, Stenhouse, Schunk, and others, and considerable difference of opinion still prevails as to the number and nature of the substances possessing dyeing properties which may be extracted from them; and we may further refer the reader to an interesting prize essay, published in the Edin. Phil. Journal for October 1854 and January 1855, entitled "*Experiments on the Dyeing Properties of Lichens,*" by Dr W. Lauder Lindsay; but the substances used in dyeing will be more fully alluded to in the chapter on calico-printing.

Colouring matter of cudbear.

The colouring matter of cudbear is obviously very nearly the same as that of archil. It has been slightly examined also by Heeren, who has pointed out some distinctive characters which it possesses.

In France, besides the lichen parellus, the lichen dealbatus is employed, and the archil is obtained by treating the lichens with putrid urine and lime. Robiquet has subjected the lichen dealbatus to a chemical analysis, and has extracted from it the matter which yields the red dye, and which he has distinguished by the name of *orcin.* It constitutes white crystals, having a sweetish and nauseous taste, melts when heated, and may be distilled over without decomposition. It dissolves both in water and alcohol. It is obvious that its properties are quite different from those of erythrin; yet the process for converting it into the red dyestuff is nearly the same as for archil and cudbear.

6. *Carthamus,* or *Safflower.*—This is the petals of the blossoms of the carthamus tinctorius, a plant formerly cultivated in Germany and France; but now the dyestuff comes usually from Egypt and the countries round the eastern part of the Mediterranean, and from India.

The method of preparing the flowers of carthamus in Egypt, as it is described by Hasselquist, is the following. After being pressed between two stones, to squeeze out the juice, they are washed several times with salt water, pressed between the hands, and spread out on mats in the open air to dry. In the day time they are covered, that they may not dry too fast with the heat of the sun, but they are left exposed to the dew of the night. When they are sufficiently dry, they are put up, and kept for sale under the name of *saffranon.* Care should be taken afterwards not to keep it in too dry a place; for unless it is a little moist, its properties are considerably impaired.

Its colouring matters

Carthamus contains two colouring substances, a yellow substance, which is soluble in water; and as it is of no use, it is extracted by the process mentioned above, by squeezing the flowers between stones till no more colour can be pressed out. The flowers become reddish in this operation, and lose nearly one half of their weight. The other colouring matter, which is red, is soluble in alkaline carbonates, and it is precipitated by means of an acid. A vegetable acid, as lemon juice, has been found to produce the finest colour. Next to this, sulphuric acid produces the best effect, provided too great a quantity, which would alter and destroy the colour, be not employed. The juice of the berries of the mountain-ash, or *rowan-tree* (*sorbus aucuparia,* Lin.), is recommended by Scheffer as a substitute for lemon juice, and it is thus prepared. The berries are bruised in a mortar with a wooden pestle, and the expressed juice, after it has been allowed to ferment, is bottled up. The clear part, which is most acid, becomes fitter for use the longer it is kept; but this operation requires a period of some months, and can only be conducted in summer.

Rouge.

From the colouring matter extracted by means of an alkali, and precipitated with an acid, is procured the substance called *rouge,* which is employed as a paint for the skin. The solution of carthamus is prepared with crystals of soda, and precipitated with lemon juice which has stood some days to settle. After being dried on delft plates with a gentle heat, the precipitate is separated, and ground accurately with talc which has been previously reduced to a very subtile powder; and on the fineness of the talc depends the difference between the cheaper and dearer kinds of *rouge.*

Carthamus furnishes about five per cent. of this matter (abstracting the talc), which is the true red colouring matter. It reddens vegetable blues while moist, whether from the acid employed in throwing it down, or from its own acid properties, has not been determined. It is insoluble in water and dilute acids, but slightly soluble in

alcohol. The solution has a rose-red colour, but when boiled becomes yellow. Ether is still a worse solvent of *rouge* than alcohol. It is insoluble in oils, both volatile and fixed; but it dissolves readily, and with a yellow colour, in alkaline leys, or alkaline carbonates. According to Dobereiner (who considers it as an acid, which he calls *carthamic*), soda saturated with it crystallizes in fine colourless needles, having a silky lustre, which become instantly red when an acid is added to them.

As a dyestuff, safflower affords only a fugitive colour, destroyed by exposure to the sun, and removed by washing. It is used, however, occasionally to give a red colour to silk.

7. *Brazil Wood.*—This wood comes from Brazil, and from Pernambuco; and in the former case is said to be the wood of the *cæsalpina sapan*, *cæsalpina crista*, and *cæsalpina vesica;* in the latter, of the *cæsalpina echinata.* These trees are large, and rich in colouring matter. The wood is very hard, and is said to sink in water. When fresh cut it is pale, but becomes reddish by exposure to the air. Its taste is sweetish. The red colouring matter of Brazil wood is very easily acted on by chemical agents, acids rendering it *yellow*, and alkalies *violet.* Chevreul has given us the following process for extracting this colouring matter in a state of purity. Digest the raspings of the wood in water till that liquid has dissolved all the colouring matter, and evaporate the infusion to dryness, to get rid of a little acetic acid which it contains. Dissolve the residue in water, and agitate the solution with litharge, to get rid of a little fixed acid which it contains. Evaporate again to dryness. Digest the residue in alcohol: filter and evaporate to drive off the alcohol. Dilute the residuum with water, and add to the liquid solution of gelatine, till all the tannin which it contains is precipitated. Filter again, evaporate to dryness, and digest the dry mass in alcohol, which will leave undissolved the excess of gelatine that may have been added. This last alcoholic solution being evaporated, the pure colouring matter of Brazil wood remains behind.

Colouring matter how obtained.

Its properties.

It is soluble in water and in alcohol, but its fine red colour does not appear till all the acid which it naturally contains is saturated. Acids give it a yellow colour. The sulphuric, nitric, and muriatic acids, give it a pale dirty yellow. Fluoric acid gives it at first a yellow colour, which is gradually altered to grayish green; while the phosphoric and citric give it a fine permanent yellow colour, which might be employed for dyeing silk and wool. For these facts we are indebted to Bonsdorf. A very minute quantity of alkali gives the infusion of Brazil wood a violet colour; it is therefore a delicate re-agent for alkalies. When neutral salts, with an alkaline base, are dissolved in the infusion of Brazil wood, it assumes a rose-red colour. Acetates act most decidedly in producing this effect. When newly precipitated alumina is agitated in this infusion, it assumes a carmine-red colour.

When Brazil wood is boiled in water, we obtain a rose-coloured solution, and the undissolved wood becomes black, but still yields to alcohol a dark-red colour. When an acid is poured into the decoction, a red precipitate falls, and the filtered liquid is yellow. Ammonia gives the decoction a purple colour, and throws down a purple precipitate. The carbonates of potash and soda render it carmine red, and throw down a precipitate of the same colour. Alum throws down an abundant carmine precipitate, but the liquid retains the same colour. The protochloride of tin gives a rose-red precipitate, and renders the decoction colourless.

Forms red ink.

Brazil wood is the substance from which red ink is prepared. The colour which it communicates to cloth has very little permanence; yet it is occasionally employed in dyeing cotton what are technically called *chemical colours*, by which is understood colours that will not resist washing. The decoction of Brazil wood, which is called juice of Brazil, is found to answer better for the process of dyeing when it has been kept some time, and has even undergone some degree of fermentation, than when it has been fresh prepared. The colour by keeping becomes of a yellowish red.

Simple Colours.

Within the last five or six years, Brazil wood has been nearly superseded by a wood imported from Africa, to which our dyers give the name of *camwood.* It is richer, and gives a finer colour, than any of the varieties of Brazil wood. It is not so much affected by alkalies, nor so liable to assume a violet shade; and the yellow colouring matter with which it is mixed gives the red a more lively appearance. We have not learned the botanical name of the tree which yields this wood.

8. *Logwood.*—This wood is usually, on the Continent, called *Campeachy wood.* It is the wood of the *hematoxylon Campeachianum*, a tree which grows to a considerable size in Jamaica, and on the eastern shore of the Bay of Campeachy. Its specific gravity is greater than that of water; it has a fine grain, and is susceptible of a fine polish. Besides the colouring matter to which it owes its value, logwood contains resin and oil, which are soluble in water; acetic acid and salts, consisting of potash and lime, combined with a vegetable acid, which are soluble in water saturated with chloride of potassium. It contains also sulphate of lime, oxalate of lime, a little alumina, and some peroxide of iron and oxide of manganese. Chevreul, to whom we are indebted for a chemical examination of logwood, has given the following process for extracting its colouring matter, which he has distinguished by the name of *hematin.*

Yields hematin.

How obtained.

The raspings of the wood are digested in water of a temperature from 122° to 131°, till every thing soluble is taken up. Evaporate the aqueous solution to dryness by a gentle heat, and treat the residue with alcohol of the specific gravity 0·843, which dissolves the colouring matter, leaving a brown residue still containing colouring matter in chemical combination. Filter the alcoholic solution, and distil it till what remains becomes of the consistence of a syrup. This syrup being mixed with some water, crystals begin immediately to be deposited. Leave it for twenty-four hours to evaporate spontaneously, then decant the liquid portion from off the crystals, and wash them with a little alcohol. The decanted liquid being left to spontaneous evaporation, will yield more crystals, and finally remains a thick uncrystallizable liquid. If it be evaporated to dryness, macerate the dry mass in cold water, and evaporate afresh: more crystals are obtained, which may be purified, like the other, by washing them in alcohol. These crystals thus obtained constitute *hematin*, or the pure colouring matter of logwood.

Its properties.

They have considerable lustre, and a scarlet colour. Under the microscope they appear to constitute needles arranged in sphericles. When rubbed on a glass it appears *orange* by transmitted light, and white by reflected light. But if we let fall on it a drop of alcohol, it appears *carmine red* by transmitted, and *yellow* by reflected light. When put into the mouth it is at first tasteless; but after some time a sensation of astringency, acridity, and bitterness, is perceived. When heated in a retort to decomposition, it gives out among other products ammonia, from which we may conclude that it contains azote. After every thing volatile is driven off, there remains fifty-four per cent. of charry matter half fused; which, when burned in the open air, leaves a quantity of lime and peroxide of iron, amounting to rather less than one per cent. of the hematin employed.

Simple Colours.

Hematin requires for solution 1000 times its weight of water. By evaporation it does not yield crystals, but when very much concentrated it is converted into a confused crystalline mass. It dissolves in alcohol and ether, and the solutions have a reddish-yellow colour. It combines with the acids, which render it yellow when added in small quantity; but when in a larger proportion they give it a red colour. Sulphurous acid and carbonic acid give the solution of hematin a pale-yellow colour. Boracic acid gives it a pale-red, and phosphoric and phosphorous acid a pale-orange colour. Arsenious acid has no sensible action on it. Sulphuretted hydrogen gas renders it yellow; and if we keep a solution of hematin charged with this gas for some time in a corked phial, it loses its colour altogether; but the colour appears if we remove the gas by means of a little oxide of lead. The salifiable bases give solution of hematin a violet, purple, or blue colour. With the fixed alkalies it forms compounds perfectly saturated and soluble. The alkaline earths fall down in combination, and have a purple colour when they fall from neutral salts, and a blue colour when from subsalts. An excess of alkali destroys the colour altogether. With the hydrated oxides of antimony, zinc, bismuth, nickel, iron, and copper, it forms blue or purple coloured compounds. The compound which hematin forms with alumina and oxide of copper at once may be fixed upon linen or cotton, and gives a blue colour like that of indigo, only it is rendered yellow by the concentrated acids, while indigo remains unchanged, unless the acid be the nitric. The protoxide of tin, when united with hematin, forms a blue-coloured compound, while its combination with the peroxide of tin is red. We see from this that the protoxide of tin possesses the characters of an alkali, while the peroxide is an acid. A solution of gelatine throws down a concentrated solution of hematin purple.

Hematin is easily altered. When a mixture of alkali and hematin is kept *in vacuo*, or in a well-corked phial, quite full, no action takes place; but when air has access, oxygen is absorbed, and the hematin quite destroyed in a few hours. During this action, the blue colour of the liquid changes first into red, and then into brown. The alkali becomes saturated with carbonic acid.

II.—*Method of dyeing Wool Red.*

All the colouring matters employed for dyeing wool red by modern dyers require a mordant to fix them. The shade of colour depends partly upon the kind of colouring matter used, partly on the mordant, and partly on the quantity of colour which the cloth is made to imbibe by the length of time that it remains exposed to the action of the dyeing liquor. The purple of the ancients, the colouring matter of which was obtained from different species of shell-fish, required no mordant; but it has already been observed that this mode of dyeing has been for ages out of use.

Madder red.

Madder Red.—Madder is only employed for dyeing coarse woollen stuffs; and the following is the process. The stuffs are first boiled for two or three hours with alum and tartar; they are then left to drain, slightly wrung out, put into a linen bag, and carried into a cool place, where they are to remain for some days. The quantities and proportions of the alum and tartar are varied according to the views of the dyer, and the shade of colour which is wanted. Some recommend five ounces of alum and one ounce of tartar to each pound of wool. By increasing the proportion of tartar to a certain degree, a deep and permanent cinnamon colour, instead of a red, is produced. This arises from the yellow tinge which is induced by means of the acid on the colouring particles of the madder. Others propose to diminish the proportion of tartar, and to employ only a seventh part. In conducting the process of dyeing with madder, the bath should not be brought to the boiling point; because at that temperature the fawn-coloured particles would be dissolved, and a different shade obtained from that which is desired. When the water is at that degree of temperature which the hand can bear, Hellot recommends the addition of half a pound of grape madder for every pound of wool to be dyed. It is then to be well stirred before the wool is introduced, which must remain for an hour without boiling, excepting for a few minutes towards the end of the process, that the combination of the colouring particles with the stuff may be more certain.

Simple Colours. Process.

Rosing.

Madder reds are sometimes rosed, as it is called, with archil and Brazil wood. In this way they become more beautiful and velvety; but this brightness is not permanent. But madder reds, even when they are most perfect, are far inferior to those obtained from lac and cochineal, and even to that produced by kermes; but as the expense of the materials is comparatively small, they are employed, as we have already observed, for coarse stuffs.

Proportion of madder.

Different authors recommend different proportions of madder. Poerner proposes to employ one third of the weight of the wool, while Scheffer limits the quantity to one fourth. In one process, Poerner added to the alum and tartar a quantity of solution of tin equal in weight to the tartar, and after two hours boiling allowed the cloth to remain in the bath, which had been left to cool for three or four days. He then dyed it in the usual way, and thus obtained a fine red. According to another process, he prepared the cloth by the common boiling, and dyed it in a bath slightly heated, with a larger proportion of madder, tartar, and solution of tin. The cloth remained twenty-four hours in the bath; and when it had become cold he put it into another bath, made with madder only, where it remained for twenty-four hours. By this process he got a fine red, somewhat brighter than the common, but inclining a little to yellow. Scheffer informs us that he obtained an orange-red by boiling wool with a solution of tin and one fourth of alum, and then by dyeing with one fourth of madder. A cherry colour is obtained, according to Bergman, by dyeing with one part of a solution of tin and two of madder, without previously boiling the wool. By exposure to the air this colour becomes deeper. By boiling the wool for two hours with one fourth of sulphate of iron, then washing it, and afterwards immersing it in cold water with one fourth of madder, and then boiling for an hour, the result is a coffee colour. But if the wool has not been soaked, and if it be dyed with one part of sulphate of iron and two of madder, the colour is a brown approaching to red.

Different mordants.

When sulphate of copper is employed as the mordant, the madder dye yields a clear brown, inclining somewhat to yellow; and a similar colour may be produced by dyeing the wool, simply soaked in hot water, with one part of sulphate of copper and two of madder. But when this mordant and dyestuff are used in equal proportions, the yellow is somewhat more obscure, approaching to green; and in both these instances exposure to the air does not produce a darker colour. Berthollet informs us that he employed a solution of tin in various ways, both in the preparation and the application of the madder; and by the use of different solutions of tin, he found, that although the tint was somewhat brighter than what is obtained by the common process, it was always more inclined to yellow or fawn colour.

Scarlet.

Scarlet.—The finest and most splendid of all colours is scarlet. This, like other colours, is of various shades, according to the quality and proportion of the colouring matter employed. The scarlet dye is communicated to wool-

Simple Colours. len stuffs by means of cochineal, the history and properties of which we have already detailed. The Mexicans, as appears from their history, employed alumina as the basis or mordant to fix the colour of cochineal; and previous to the discovery of the solution of tin, the use of the same substance seems to have prevailed in Europe. The fine colour obtained from the latter received, as we have already mentioned, different names in different places; as that of *bow dye* in England, *scarlet of the Gobelins* in France, and in Holland *Dutch scarlet*.

Process. In the process for dyeing scarlet two operations are necessary. The first is denominated the boiling, and the second is distinguished by the name of finishing or reddening.

Boiling. The operation of boiling, which is the first part of the process, is conducted in the following manner:—For one hundred pounds of cloth, six pounds of pure tartar are added to the water, which is made pretty warm. The bath is then to be briskly stirred; and when the heat has increased a little more, half a pound of powdered cochineal is to be added, and the whole is then to be well mixed. The next moment five pounds of a very clear solution of tin are to be poured in and carefully mixed. When the bath begins to boil, the cloth is introduced, and briskly moved for two or three turns: after which it is moved more slowly. The boiling having continued for two hours, the cloth is taken out, exposed to the air, and carried to the river to be well washed.

Reddening. In the preparation of the second bath, which is for the reddening, the boiler is to be emptied, and when the bath has just reached the boiling point, five pounds and three quarters of cochineal, previously powdered and sifted, are to be added. These are to be carefully mixed; and after having ceased stirring, when a crust has formed on the surface, and opened of itself in several places, thirteen or fourteen pounds of solution of tin are poured in. Should the bath during the boiling rise above the edge of the boiler, it may be cooled with a little cold water. This solution being well mixed, the cloth is put in, and two or three times quickly turned. It is then boiled in the bath for an hour, taking care to keep it under the surface. It is afterwards taken out, exposed to the air, and, when it has cooled, washed in the river and dried.

Proportion of ingredients. There are no determinate proportions of cochineal and solution of tin in either of these operations. Hellot informs us that some dyers employ two thirds of solution of tin and one fourth of cochineal in the boiling or first operation, and the other one third of the solution of tin with the remaining three fourths of the cochineal in the second operation, or the reddening. He adds farther, that the use of tartar gives a greater degree of permanency to the colour, provided the proportion do not exceed one half the weight of the cochineal employed. According to Berthollet, several dyers at present adopt this practice. Tartar, he observes, promotes the solution of the colouring matter; and this effect is greater when it is ground with the cochineal, after which it is found that the residuum is more completely exhausted. But this consideration is of inferior consequence when the operations are successively performed, because any colouring matter that may remain in the residuum is employed in the next operation. It ought not, however, to be overlooked, that the tartar communicates to the colour a rosy hue.

Shorter process. It is the practice of some dyers not to remove the cloth out of the boiling. They merely refresh it, and perform the operation of reddening in the same bath. When this is done, the infusion of cochineal, made in a separate vessel, and mixed with the proper proportion of solution of tin, is added. By conducting the process in this way the scarlet is supposed to be equally fine, and there is a considerable saving of time and fuel.

Brighter red. To give scarlet the bright lively red, which, as it approaches to the colour of fire, has been distinguished by the name of *fiery scarlet*, a yellow tinge is communicated by boiling fustic in the first bath, or by adding a little turmeric to the cochineal. A larger proportion of the solution of tin also produces this yellow shade, but it renders the cloth harsh, and limits the action of the colouring matter. The use of fustic or turmeric, therefore, although the colour obtained from them is not permanent, is preferable to an excess of the solution of tin. When these substances are used, the inside of the cloth, when it is cut, appears yellow; but in the ordinary processes, the cochineal, it is found, does not penetrate the cloth, for when no other substance is employed the cloth is internally white.

Tin and copper boilers. The use of tin boilers is recommended in dyeing scarlet. When copper boilers are employed, the acid acts on the metal, and thus forming a solution, injures the beauty of the colour. Tin boilers, however, are attended with several inconveniences. It is difficult to procure them of sufficient size, and they are apt to be melted by the incautious continuance of the fire after they have been emptied. In the use of copper boilers there are several necessary precautions. They must be kept very clean, the acid liquor should not be allowed to remain in them for any length of time, and some contrivance should be adopted to prevent the cloth from touching the metal, either by using a net or a wicker basket.

Different proportions of ingredients. Different proportions of materials, we have observed, are recommended by different authors. For the boiling, Scheffer directs an ounce and a half of solution of tin, with an equal quantity of starch, and as much tartar, to every pound of cloth. The effect of the starch is to give more uniformity to the colour. When the water boils, a dram of cochineal is to be added; it is then to be well stirred, and after the wool is introduced, to be boiled for an hour, taken out, and washed. The proportions for the reddening bath, in which the wool is to be boiled half an hour, are half an ounce of starch, three fourths of an ounce of solution of tin, half an ounce of tartar, and seven drachms of cochineal. In Scheffer's process, it may be observed, the proportion of solution of tin is smaller than in that of Hellot, but the quantity of tin in the solution of the former is greater than in that of the latter.

Poerner's process. Poerner has described three principal processes, according to the variety of the shade of the scarlet. He uses no cochineal in the boiling; the materials of which are one ounce and six drachms of tartar, and an equal weight of solution of tin, the latter being added after the tartar is dissolved, for every pound of cloth. As soon as the boiling has commenced, the cloth is introduced, and it is boiled for two hours. For the reddening of the first process he employs two drachms of tartar and one ounce of cochineal, adding gradually afterwards two ounces of solution of tin. For the reddening of the second process the same quantity of cochineal and solution of tin, without any tartar, is employed. In the reddening of the third process, two drachms of tartar with one ounce of solution of tin, one ounce of cochineal, and two ounces of common salt, are directed to be used. The colour produced in the first process has the deepest shade, that of the second is more lively, while that of the third is paler and brighter.

Different shades. By the use of tartar in the reddening in different proportions, various shades of scarlet may be obtained. When it is employed, the shade is deeper and fuller; but when it is entirely omitted, the scarlet approaches to an orange colour. The shade of colour also is subject to considerable variety, from the different degrees of strength of the solution of tin. To ascertain this effect, Berthollet made a number of experiments. He found that a solution of tin, composed of sixteen parts of nitric acid, two of muriate of

Simple Colours

ammonia, and three of tin, produced a deeper shade than when the proportions of the acid and muriate of ammonia were equal, with only two parts of tin. The last proportions, he observes, succeeded best. Four parts of water were mixed with the solution. When the proportion of muriate of ammonia amounted only to half a part, the colour was brighter, and inclining to orange.

Use of common salt.

Common salt has the effect of increasing the brightness of scarlet, while it is also attended with the advantage of causing the colour to penetrate deeper into the cloth. It seems difficult to explain why common salt, which gives a deeper shade to the colour of the infusion of cochineal, and indeed produces a similar effect on colours in general, should diminish the intensity of the colour of scarlet. The proportion of common salt mentioned above is, according to Poerner, the greatest that can be employed. When less is used, the shade, though lighter, is more agreeable. By adding five ounces of white sugar to the ingredients of the second process, a fine colour, which is always lighter than that of the first process, will be obtained. The colour, it is said, is more permanent, and the shade more agreeable, when the cloth is left twenty-four hours in the boiler after it has cooled.

Method of using the lac dye.

For dyeing fine woollen cloth the lac dye is commonly used. It comes to the dyer in the state of a fine powder, having a brownish-red colour, inclining to violet. It contains much less colouring matter than cochineal, but is incomparably cheaper. To dye forty-three pounds of fine woollen cloth, six pounds of lac, three pounds of cream of tartar, and five pounds of tin mordant are put into a dyeing vessel, either of tin, or at least lined with tin, with a sufficient quantity of water. The whole is brought to the boiling temperature, and after it has boiled briskly a sufficient time to dissolve the colouring matter, the cloth is passed through it for about an hour, or till it has acquired the requisite depth of colour.

Tin mordant, how made.

The tin mordant used is made by dissolving two ounces of tin in thirty pounds of aquafortis mixed with one pound of muriatic acid. The solution is transparent, and it is kept in well-corked bottles for use. The tin is doubtless in the state of protochloride, though it sometimes also gets into the state of perchloride. Either state will answer, but in the second case the dyeing process is much slower, the cloth not seeming to imbibe the perchloride of tin so rapidly as the protochloride. From the above proportions, it is obvious that to dye forty-three pounds of woollen cloth scarlet, one third of an ounce of tin converted into protochloride is sufficient. This is rather less than 146 grains of tin; so that each pound of the woollen cloth combines with not more than 3·4 grains of tin. It is obvious from this that the particles of tin must be exceedingly minute indeed, otherwise 3·4 grains of tin could not be so minutely divided as to cover the surface of a pound weight of woollen cloth.

When the dyer wishes the scarlet to assume a brighter shade, he sometimes adds a little quercitron bark, which, by the yellow colour which it induces, adds materially to the brightness of the colour. This plan was first suggested by Dr Bancroft, and it has been since pretty generally acted on.

Dr Bancroft recommended the tin mordant to be prepared by dissolving tin in muriatic acid mixed with one fourth of its weight of sulphuric acid. This solution, he says, answers very well, and is much cheaper. We cannot find, however, that any of the dyers in this country follow that process. We can hardly think that the present method of using so much nitric and so little muriatic acid is a good one. The object being to obtain a protochloride of tin, one would think that muriatic acid would be a better vehicle. Tin dissolves in this acid very well, and the protochloride of tin formed in this way is easily obtained in crystals. But the tin mordant, as prepared by the dyers, contains a great excess of nitric acid; and we cannot avoid suspecting that this excess is connected with the shade of scarlet produced. The nitric acid doubtless renders a part of the colouring matter of the lac yellow, and thus changes the dark crimson colour natural to this dyestuff into scarlet.

Simple Colours.

Cochineal is still employed to a considerable extent in dyeing the finest kinds of woollen cloth scarlet. The process is precisely the same as when lac is employed, remembering only that cochineal is much richer in colouring matter than lac, and that therefore a smaller quantity will serve. Dr Bancroft introduced the method of putting the cochineal, the tin mordant, and the tartar into the dyeing vessel at once, and dissolving them all together in water before the cloth is passed through the liquid; and this method is pretty generally though not universally followed.

Dr Bancroft's method of using quercitron bark to supply the place of a portion of the cochineal, is likewise pretty generally followed. The price of cochineal, in consequence of the introduction of the lac dye, has sunk from thirty shillings the pound to about nine shillings and sixpence. This makes the saving not so considerable in point of expense as it was when Bancroft wrote, though even at present it is an important saving.

Different shades of scarlet.

To produce different shades of scarlet, and the other colours which are derived from it, all that is necessary is to vary the proportions of cochineal, tartar, and solution of tin; and for the shades which incline most to yellow, the addition of quercitron bark or fustic is requisite. The use of the tartar is to deepen the colour, and the solution of tin produces a shade of orange. When the shade of colour required to be communicated to the stuff is light, the time of continuing the process must be shortened.[1]

Crimson.

Crimson.—The processes which are employed to dye wool a crimson colour are two. The stuff is either dyed crimson at once, or the crimson shade is communicated to it after being previously dyed of a scarlet colour. To dye crimson by a single process, a solution of two ounces and a half of alum and an ounce and a half of tartar for every pound of stuff, is employed for the boiling, and the stuff is afterwards to be dyed with an ounce of cochineal. It is usual also to employ solution of tin, but in smaller proportion than for dyeing scarlet. The processes employed, it is scarcely necessary to observe, must vary according as the shade wanted is deeper or lighter, or more or less distant from scarlet. Common salt is also employed by some in the boiling. To render the crimson deeper, and to give it more bloom, archil and potash are frequently used; but this bloom, it ought to be observed, is extremely fugacious. By adding tartar and alum, the boiling for crimson is sometimes prepared after a scarlet reddening; and it is said that the colour possesses more bloom when both the boiling and reddening are made after scarlet, than when the crimson is dyed in a fresh bath prepared on purpose. In dyeing these colours the wild cochineal may be employed; but as it contains a smaller proportion of colouring matter, the quantity must be greater.

dyed by one process,

or by the conversion of scarlet.

Different substances, as the alkalies, alum, and earthy salts in general, convert the colour of scarlet to crimson, which is the natural colour of cochineal. To effect this, the stuff previously dyed scarlet is boiled for an hour in a

[1] Berthollet, ii. 194.

Simple Colours.

solution of alum, the strength of which is to be regulated by the depth of shade required. In conducting this process, it is necessary to observe, that water impregnated with earthy salts has a considerable effect in varying the shade, so that the quantity of alum employed must be proportioned to the purity of the water. Hellot tried soap, soda, potash, and some other substances, and although they produced the crimson, yet it was of a deeper shade, and had less lustre, than what was produced by means of alum. Ammonia produced a good effect, but, from its great volatility, a considerable proportion must be put into the bath, moderately heated, with a little sal ammoniac, and an equal quantity of potash. By this process the stuff became of a bright rosy colour, and thus rendered a smaller quantity of cochineal necessary. Poerner directs the stuff, previously dyed scarlet, to remain twenty-four hours in a cold solution of sal ammoniac and potash.

Half-grain crimson, &c.

To produce crimsons, as well as scarlets, in half grain, madder is to be substituted for half the quantity of the cochineal; or in other proportions, according to the shade desired. The same boiling is given as for scarlet in grain, and the other parts of the process are to be conducted as for reddening the scarlet or crimson. Even the common madder red assumes a greater degree of lustre when the boiling is made after the reddening for scarlet.

At present we are not aware that kermes is ever employed by the dyers in this country. The use of this dye-stuff seems to have been completely superseded by cochineal and lac dyes. Certainly the colour given by kermes is not so fine as that given by these substances, but it has the advantage of being exceedingly durable.

III.—*Method of dyeing Silk Red.*

Different processes with madder.

Madder Red.—The colour which is obtained from madder does not possess sufficient brightness for dyeing silk. We shall here, however, describe some of the processes which are employed for this purpose. That of De la Folie is the following: Half a pound of alum is to be dissolved in each quart of hot water, and two ounces of potash are afterwards to be added. When the effervescence has ceased, and the liquor has become clear, the silk must be kept in it for two hours, after which it is to be washed and put into the madder-bath. The silk which is dyed in this way becomes more beautiful by means of the soap proof. The process of Scheffer is somewhat different. For each pound of scoured silk he directs a solution of four ounces of alum and six drachms of chalk to be prepared. When the sediment has formed, the solution is to be decanted, and having become quite cold, the silk is immersed in it, and left for eighteen hours. It is then taken out and dried, and afterwards dyed with an equal weight of madder. The colour thus obtained is of a dark shade. Mr Guhliche describes another process. For every pound of silk he proposes a bath of four ounces of alum and one ounce of solution of tin. When the liquor has become clear it is decanted, and the silk carefully soaked in it for twelve hours, after which it is to be immersed in a bath with half a pound of madder softened by boiling with an infusion of galls in white wine. The bath is to be kept moderately hot for an hour, and then made to boil for two minutes. The silk, being taken from the bath, is to be washed in a stream of water, and dried in the sun. The colour thus obtained is very permanent. By leaving out the galls it is clearer. The brightness of the first colour may be considerably increased by passing the stuff through a bath of Brazil wood, to which one ounce of solution of tin is added. In this way the colour becomes extremely beautiful and durable.

Process with Brazil wood.

Silk is sometimes dyed with Brazil wood, and the colour thus obtained has been distinguished by the name of *false crimson*, to distinguish it from the more durable colour which is produced by cochineal. The silk, after being boiled with soap, is to be alumed. It is then to be refreshed at the river, and dipped in a bath more or less charged with Brazil juice, according to the depth of shade required. If pure water be employed, the colour will be too red for crimson; but to remedy this, the stuff may be passed through a weak alkaline solution, or a little alkali may be added to the bath, or the stuff may be washed in hard water till it has acquired the proper shade. To deepen the shade of false crimsons or dark reds, the solution of logwood is added to the Brazil bath, the silk being previously impregnated with the latter; or a little alkali may be added, according to the shade required.

With cochineal.

The crimson produced by cochineal is called *grain crimson*, to distinguish it from false crimson. The silk, being well cleansed from the soap at the river, is to be immersed in alum liquor of the full strength, and to remain for a night. It is then to be washed and twice beetled at the river. The bath is prepared by filling a long boiler two thirds with water, to which are added, when it boils, from half an ounce to two ounces of powdered white galls for every pound of silk. When it has boiled for a few moments, from two to three ounces of cochineal, also powdered and sifted, for every pound of silk, are put in, and afterwards one ounce of tartar to every pound of cochineal. When the tartar is dissolved, one ounce of solution of tin is added for every ounce of tartar. In the preparation of this solution of tin, the following proportions are recommended by Macquer. For every pound of nitric acid two ounces of sal ammoniac, six ounces of fine grain tin, and twelve ounces of water, are employed. When these ingredients are mixed together, the boiler is to be filled up with cold water; and the proportion of the bath for every pound of silk is about eight or ten quarts of water. In this the silk is immediately immersed and turned on the winch till it appear to be of a uniform colour. The fire is then increased, and the bath is kept boiling for two hours, taking care to turn the silk occasionally. The fire is afterwards put out, and the silk put into the bath, where it is allowed to remain for a few hours longer. It is then taken out, washed at the river, twice beetled, wrung, and dried. Two processes are recommended by Scheffer and Macquer. In that of the former, a greater proportion of cochineal is employed in the dye-bath; but in that of the latter, a yellow ground is previously communicated to the silk. The colour which is thus obtained resists the action of soap, and is more durable than that which is produced by means of carthamus.

Poppy red.

To obtain other shades of red, the above processes must be varied. If, after the silk has been wrung out of the solution of tin, it is steeped for a night in a cold solution of alum, in the proportion of one ounce to a quart of water, wrung, and dried, then washed and boiled with cochineal, it will only appear of a pale poppy colour; but a fine poppy red may be produced by steeping it twelve hours in the solution of tin, diluted with eight parts of water, then left all night in the solution of alum, washed, dried, and passed through the two baths of cochineal, taking care to add to the second bath a small quantity of sulphuric acid. The same colour may be produced by dyeing the silk previously with anotta, and then passing it successively through a number of baths prepared with an alkaline solution of carthamus, to which lemon juice has been added, till it acquire a fine cherry-colour. To brighten the colour, the silk, after being dyed, may be immersed in hot water acidulated with lemon juice.

Cherry red, &c.

Other shades of red, as a cherry red, and flesh red, are also produced by carthamus. For a cherry red it is not necessary that the stuff be previously dyed with anotta.

Simple Colours.

and the proportion of colouring matter is smaller. A flesh-red colour is obtained by adding a little soap to the bath, which has the effect of softening the colour, and of retarding the action of the colouring matter on the stuff. To produce dark shades, it is sometimes usual to mix archil, and by this means the expense is diminished.

Scarlet. Those who have produced a colour on silk which comes nearest to scarlet, Berthollet observes, begin with dyeing the silk crimson. It is then dyed with carthamus, and lastly it is dyed yellow without heat. By this process a fine colour is obtained; but the dye of the carthamus is not permanent, as it is destroyed by the action of the air, and the colour becomes deeper. The following is Dr Bancroft's process. In a solution of murio-sulphate of tin, diluted with five times its weight of water, the silk is to be soaked for two hours; and after being taken out, it is to be wrung and partially dried. It is then to be dyed in a bath prepared with four parts of cochineal and three of quercitron bark. In this way a colour approaching to scarlet is obtained. To give the colour more body, the immersion may be repeated both in the solution of tin and in the dyeing bath; and the brightness of the scarlet is increased by means of the addition of carthamus. A lively rose colour is produced by omitting the quercitron bark, and dyeing the silk with cochineal only; and by adding a large proportion of water to the cochineal, a yellow shade is obtained, which changes the cochineal to the compound scarlet colour.[1]

Rose colour.

IV.—*Method of dyeing Cotton and Linen Red.*

The dyestuff usually employed to give a red colour to cotton and linen is madder. It is easier to dye cotton than linen; but as the processes are the same for each, one general description will apply to both. There are two kinds of madder red; the one is called *simple* madder red, and the other, which was originally invented in the Levant, is distinguished in this country by the name of *Turkey red.* This last constitutes by far the brightest and most beautiful and permanent red which is communicated to cotton; we shall therefore proceed to give a somewhat particular account of the process.

The method was first put in practice in Glasgow about forty years ago, by M. Papillon, a French gentleman, who established a Turkey-red dye-work along with Mr Mackintosh. He made an agreement with the commissioners and trustees for manufactures in Scotland, that the process was to be by them published for the benefit of the public at the end of a certain term of years. The period agreed upon having expired in 1803, the trustees laid a minute account of the different processes before the public. Since that period Turkey-red dyeing has been conducted in Glasgow upon a very extensive scale. Different individuals, possessed of both chemical skill and considerable sagacity, have studied the different parts of this very complicated method of dyeing. The effects of each individual operation have been carefully investigated, and the whole has been somewhat shortened and simplified, though it still constitutes the most complicated process in the whole art of dyeing. The Turkey-red dye is practised by a considerable number of persons in Glasgow; but the oldest, and perhaps the most extensive establishment, is that of Henry Monteath and Company at Rutherglen Bridge. The character of that house has been long established, and the beauty of their Turkey-red dye is known and appreciated in every part of the globe where British manufactures are known. From Glasgow the Turkey-red dye has gradually made its way into Lancashire.

Cotton cloth which is to receive the Turkey-red dye is never bleached beforehand; because it has been found that the first parts of the processes succeed better with unbleached than with bleached cloth.

The rot steep. 1. The first step of the dyer is to remove the weaver's dressing. This is done by steeping the cloth in a weak alkaline ley. To this the technical name of the *rot steep* is given. From four to five pounds of caustic potash are generally employed for every 100 lbs. of cotton cloth. The temperature of the solution is from 100° to 120°, and the cloth is kept in the steep for twenty-four hours, and then well washed.[2]

2. From seven to ten pounds of carbonate of soda are dissolved in a sufficient quantity of water to keep the cloth (supposed always to weigh 100 lbs.) wet. In this ley the cloth, previously deprived of the weaver's dressing, is boiled for some time.

The soap steep. 3. The process which we are now going to describe is the one upon which the goodness of the Turkey-red dye depends more than upon any of the others. Without it the dye cannot be produced upon new cloth; but when cloth which has been frequently washed with soap is to be dyed (an old cotton shirt, for example), this process may be omitted altogether. It is evident from this that soap communicates to cotton cloth the same properties as the process which we are now going to describe.

A liquor is composed of the following ingredients:

1 gallon of gallipoli oil,

1½ gallon of soft sheep dung,

4 gallons of solution of carbonate of soda, of the specific gravity 1·06,

1 gallon of solution of pearl ash, of the specific gravity 1·04,

mixed with a sufficient quantity of cold water to make up twenty-two gallons. The specific gravity of this liquor should be from 1·020 to 1·025.

This liquor has a milk-white appearance, and is in fact a kind of incipient soap. It is put into a large wooden open cylindrical vessel, called the *liquor tub* (see Plate CCXIX., figs. 1 and 2), and is kept continually in a state of agitation by a kind of wooden levers, driven round in it by machinery put in motion by the steam-engine. This liquor is conveyed by a tin pipe to the *padding machine*, which is situated in an apartment below. Several sections of this machine are given in the same plate, fig. 3, 4, and 5. A kind of trough in this machine is kept always full of the milky liquor, and the pieces of cloth to be dyed are made to pass through this liquid, and are thoroughly soaked with it.

By this process the cloth is impregnated with the soapy matter, and the longer this matter is left undisturbed on the cloth, the better does it take the dye. Fourteen days is the least period that this impregnation is allowed to remain.

The sheep dung gives the cloth a dark-green colour, and is found materially to assist the bleaching which the cloth afterwards undergoes. This bleaching goes on much more rapidly with than without the sheep dung, especially when the cloth is exposed on the grass between the different operations. In what way the sheep dung contributes to this acceleration has not been determined, but the fact is certain.[3]

4. When the weather is favourable, the cloth, after be-

---

[1] *Philosophy of Permanent Colours*, 312.

[2] In general the alkaline ley of No. 9 is worked up in this process, and when this is done less potash is required.

[3] No advantage has been found to result from using the alkalies caustic in this process; and a mixture of potash and soda answers much better than soda alone.

Simple Colours.

ing impregnated with the oleaginous liquor, is spread upon the grass to dry. But should the weather be rainy, as it would not do to allow the oleaginous liquid to be washed out by the rain, the goods are dried in the stove.

5. After the cloth has been dried in the stove, it is a second time impregnated with the oleaginous liquid described in No. 3, by means of the padding machine. It is then spread on the grass for some hours if the weather be favourable, and ultimately dried in the stove.

The impregnation with the oleaginous liquor, the exposure on the grass, and the stove drying, are repeated a third time. When the weather is rainy, which prevents exposure on the grass, and obliges the workmen to dry the cloth at once in the stove, the impregnation with the oleaginous liquor is sometimes repeated a fourth time.

Upon the sides of the tubs in which the oleaginous liquor is kept, a white solid crust gradually accumulates. This matter being examined, was found to consist almost entirely of phosphate of lime. It was doubtless derived from the sheep dung with which the saponaceous liquid was mixed.

6. The next process is to steep the cloth in a weak solution of pearl ash, of the specific gravity 1·0075 to 1·01, heated to the temperature of 120°. From this liquor it is wrung out and again dried.

7. A mixture is now made of the following substances:

1 gallon gallipoli oil,
3 gallons soda ley of specific gravity 1·06,
1 gallon caustic potash ley of specific gravity 1·04,

diluted with as much water as will make up the whole to twenty-two gallons. In this liquid, which is milky, like the preceding, and which contains an imperfect soap, the cloth used formerly to be tramped with the hand, and then wrung out. It is now soaked with the liquid by means of the padding machine, in the manner described under No. 3.

If the weather be fine, the cloth thus impregnated with the soap is exposed on the grass. It is then dried in the stove.

8. The above process (No. 7) is repeated thrice; and after each soaking in the saponaceous liquor, the cloth is exposed on the grass for some hours, and then dried in the stove.

9. The cloth, thus so many times soaked in the saponaceous liquor, is now steeped in a mixed ley of pearl ash and soda of the specific gravity from 1·01 to 1·0125, heated to the temperature of 120°. After being taken out of the steep, and allowed to drain for a few hours (taking care to preserve the liquor), the cloth is well washed. The object of this process is to remove any superfluous oil with which the cloth may be impregnated, the object being that all the oil adhering to the cloth should be in combination with an alkali. About half the alkali used in this process disappears during the steeping. The remaining liquor, which is about half as strong as at first, is reserved for future use. The cloth thus washed clean is dried in the stove.

The galling.

10. The preceding washing is necessary for the success of the next operation, called the *galling;* for the nutgall liquor will not be imbibed by the cloth unless it be thoroughly freed from all uncombined oil, which would give it a greasy feel. If the first steeping in alkali and washing has not fully accomplished this necessary object, they ought to be repeated.

For the galling, eighteen pounds of Aleppo galls are to be boiled for four or five hours in twenty-five gallons of water till it is reduced to about twenty gallons; and the liquid being now passed through a sieve, is sufficient for impregnating 100 lbs. of cloth with the requisite quantity of nutgalls. Of late years, sumach from Sicily has been substituted for nutgalls, thirty-three lbs. of sumach being considered as equivalent to eighteen lbs. of nutgalls. Sometimes a mixture of nine lbs. nutgalls and sixteen and a half lbs. of sumach is employed.

Through this decoction the cloth is either tramped by the hand, or it is passed and soaked in it by means of the padding machine. The temperature of the decoction should be from 80° to 100°. It is unnecessary to steep the cloth in the gall liquor; a complete soaking is all that is necessary. The cloth, thus soaked in a decoction of fustic, comes out dyed yellow, a colour which serves to improve the madder red by rendering it more lively.

The aluming.

11. The next process is to fix the alumina mordant upon the cloth. This step is essential, because without it the madder dye would not remain fixed in the cloth, but would be easily washed out. Accordingly the depth of the shade of red depends entirely upon the quantity of alumina fixed on the cotton. In a preceding part of this article we have stated the quantity of alumina fixed by this process upon the surface of a square yard of cloth.

In this country common alum is usually employed; but in many parts of the Continent they use acetate of alumina. The high price of that article prevents its employment in Britain. Acetate of alumina, however, is made in this country by the chemical manufacturers, and largely used by the calico-printers. It is made by mixing acetate of lime (obtained by saturating the acetic acid formed when wood is distilled with lime) with a solution of alum, and afterwards drawing off the clear liquor; or by mixing acetate of lead with solution of alum, though that process is more expensive.

Alum (as has been explained under the article ALUM) is a double salt, composed of

3 atoms sulphate of alumina,
1 atom sulphate of potash,
24 atoms water.

To form the alum liquor used by the Turkey-red dyers: To a solution of alum in water of the specific gravity 1·04 as much pearl ash, soda, or chalk is added as is sufficient to precipitate the alumina contained in the alum. Through this muddy liquor, which should have a temperature of from 100° to 120°, the cloth is passed and steeped for twelve hours. The alumina, in the state of extreme division which it has when thus newly precipitated, is readily imbibed by the cloth, and unites with the fibres of the cotton.

12. The cloth thus united to alumina is stove dried, and then washed out of the alum liquor.

13. These essential preliminary steps having been taken, the cloth is ready for being dyed.

The dyeing.

From one to three lbs. of madder reduced to the state of powder for every pound of cloth is employed, the quantity depending upon the shade of colour wanted. The cloth is entered into the boiler when the water is cold. It is brought to boil in one hour, and the boiling is continued for two hours. During the whole of this time the cloth is passed through the dyeing liquor by means of the winch.

For every twenty-five lbs. of cloth dyed, one gallon of bullock's blood is added. This is the quantity of cloth dyed at once in a boiler. This addition of blood is indispensable for obtaining a fine red colour Various attempts have been made to dispense with the use of blood in Turkey-red dyeing, but hitherto they have been unsuccessful. No satisfactory explanation of the way in which the blood acts has been given. For our own parts, we are disposed to consider the colouring matter of the blood as the useful ingredient. It is probably fixed upon the cloth to a certain extent, and by its fine scarlet tint it is obvious that it must improve the colour of madder red.

Simple Colours.

14. After the cloth has been thus dyed, it was formerly customary to steep it in a solution the same as that described in No. 7. This was called the *cuing* process. It is now generally dispensed with, and is unnecessary if the cloth has been well cleaned before the galling process. The object of it is merely to dissolve any greasy matter which may continue attached to the cloth, and to form a soap with it, which assists in the subsequent process.

The clearing.

15. Madder contains two colouring matters, a brown and a red. Both are fixed upon the cloth by the dyeing process. The consequence is, that the cloth has a dirty brownish-red colour, which is any thing but agreeable. Fortunately the brown colouring matter is not nearly so *fixed* upon the cloth as the red colouring matter. The next process, called the *clearing process*, is to get rid of the brown colouring matter. For this purpose the cloth is boiled from twelve to fourteen hours, in a mixture of five pounds of soda, eight pounds of soap, and sixteen to eighteen gallons of the residual liquor of No. 9, with a sufficient quantity of water. These quantities are supposed to be employed to clear a hundred pounds of cloth. By this process the brown colouring matter is almost wholly removed, and the cloth begins to assume the fine tint which distinguishes Turkey-red dyed cloth.

16. The next process serves not merely to remove the brown colouring matter more completely, but also to improve the shade of red. Five or six pounds of soap, and from sixteen to eighteen ounces of protochloride of tin, in crystals, are dissolved in water, in a globular boiler, into which the cloth is put. The boiler is then covered with a lid which fits close, and the boiling is conducted under the pressure of two atmospheres, or at the temperature of $250\frac{1}{2}°$. The boiler is furnished with a safety valve and a small conical pipe, the extremity of which has an aperture about $\frac{5}{16}$ths of an inch in diameter, from which there issues a constant stream of steam during the operation. We have given a section and elevation of this boiler in Plate CCXX. fig. 8 and 9, and in fig. 10 a plan of its top, and in fig. 11 of its lid. The use of the salt of tin is to give a shade of scarlet to the cloth. The oxide of tin seems to combine with the oleaginous acid of the soap, and this insoluble soap unites with the red colouring matter of the madder fixed upon the cloth, and improves the shade of colour.

17. After these processes, the cloth is spread out on the grass and exposed to the sun for a few days, which finishes the clearing. It is seldom that recourse is had to a bleaching liquor, consisting of a solution of chloride of lime in water, especially when a salt of lime is used in the cleaning process. When this method is employed, however, one gallon of the solution of chloride of lime, of the specific gravity 1·015, is mixed with twenty gallons of pure water. The cloth is immersed in this dilute solution from five to ten minutes, which is sufficient for completing the clearing.

Remarks on the processes.

Such are the different steps in fixing this beautiful and permanent colour, as practised in the principal works in Glasgow. Many attempts have been made to shorten these tedious processes, but hitherto these attempts have been unsuccessful. The impregnation with oil, or rather with soap, is essential, as is evident from this, that if one, two, or three of these operations be omitted, the red is inferior in proportion to the number of omissions.

Cloth bleached by chloride of lime does not produce a good red. Probably the fibres of the cotton wool are combined with lime, or rather sulphate of lime, which, by decomposing the oleaginous soap, prevents it from being deposited upon and combining with the cloth. But cloth bleached by the old process, namely, boiling in ley or soap, and exposing to the action of the sun, answers perfectly, and will produce as good a red as when unbleached cloth is used; but there would result no saving from bleaching the cloth in this way before commencing the impregnation with the oleaginous soap, because the bleaching is effected betwixt the oil operations by exposing the cloth on the grass.

The colour would be as good without the galls or sumach as with them. But there would be considerable difficulty in sufficiently impregnating the cloth with the solution of alum without its being previously passed through the gall decoction, and more particularly if the cloth be in the least degree greasy. The use of the galls, then, is to facilitate the fixation of the alumina upon the cloth.

Alumina is essential to the fixation of the colour; for without it the madder dye would be fugitive, and would disappear whenever the cloth was washed. The subsequent *clearing* operations would completely remove both the colouring matters of the madder, unless it were cleared along with a quantity of cloth that had received alumina, and been dyed a deep red. In that case the unalumed cloth will receive a little alumina from the alumed portion. This will serve to fix the colour; but as the quantity of alumina which in such a case is imbibed is very small, the red colour will be very pale. It is in this way that the two shades of red, the deep and the pale, which are often seen upon garments and furniture dyed Turkey red, are given. These two shades, by their contrast, frequently add considerably to the beauty of the pattern. The fustic, as well as the tin, probably serves to render the red colour more lively by the shade of yellow which they superinduce.

The three essential processes in the Turkey-red dyeing are, the impregnation with oleaginous soap, the impregnation with alumina, and the dyeing with madder. The last communicates the colour, the second fixes the colour, and the first gives beauty to the colour.

For the better understanding of the Turkey-red processes, we have got drawings made of the principal machinery used.

Figs. 1 and 2, Plate CCXIX., exhibit a section and plan of the *liquor tub*, in which the mixture of oil and alkali is put, with its agitators to prevent the oil from separating and swimming on the surface. From the liquor tub (which is placed in an upper room) the liquor passes by a tin pipe to the padding machine, represented in various ways in figs. 3, 4, and 5.

It consists essentially of a box for holding the liquor, through which the cloth passes; and afterwards it goes between two rollers, the distance between which regulates the quantity of liquor which the cloth retains.

a, is the lapper for folding the cloth.

b, a compound lever for regulating the pressure.

c, the box for containing the liquor.

d, a frame or *scrae* for laying the cloth on before it passes through the liquor.

e, pulleys for moving the lapper; and

f, the cylinders between which the cloth passes. They regulate, by their distance from each other, the quantity of liquor allowed to remain in the cloth.

Figs. 6 and 7 represent the elevation and plan of a *dyeing box* on the latest and most improved construction.

a, the winch for moving the cloth through the liquor while dyeing.

b, steam pipe for supplying the vessel with steam.

c, *c*, *c*, the dotted part, represents the valves through which the steam enters into the vessel.

d, *d*, *d*, *d*, divisions of the vessel for different pieces of cloth.

e, catch for stopping or setting on the winch at pleasure.

f, valve for regulating the quantity of steam admitted.

Simple Colours.

Figs. 8 and 9 represent a section and elevation of the clearing boiler. Fig. 10 represents exactly the mouth of this boiler, and fig. 11 the lid or cover. On the upper edge of this cover there is fixed all round a layer of hemp (a piece of flat rope). The lid is slipt into the inside of the boiler, and by the piece of rope it attaches itself exactly to the inside. The elasticity of the steam within presses it firmly against the inside rim of the mouth, and renders it quite steam-tight.

Scarlet with cochineal. The scarlet colour communicated to cotton by means of cochineal is far from being permanent; but if this colour is wished to be communicated to cotton, Dr Bancroft recommends to steep the cotton, previously moistened, for half an hour, in a diluted solution of murio-sulphate of tin, and then having wrung the cotton, to plunge it into water in which as much potash has been dissolved as will neutralize the acid adhering to the cotton, so that the oxide of tin may be more copiously fixed on the fibres of the cotton. The stuff being afterwards rinsed in water, may be dyed with cochineal and quercitron bark, in the proportion of four pounds of the former to two and a half or three pounds of the latter. A full bright colour is thus given to the cotton, which will bear slight washings with soap, and exposure to the air. Indeed the yellow part of the colour derived from quercitron bark will bear long boiling with soap, and will resist the action of acids.

Crimson. With the aluminous mordant, as it is usually applied by calico-printers for madder reds, cotton dyed with cochineal receives a beautiful crimson colour, which will bear several washings, and resist the weather for some time. It is not, however, to be considered as a fixed colour. Dr Bancroft is of opinion that the addition of a small portion of cochineal in dyeing madder reds upon the finer cottons, would be highly advantageous to the calico-printers. By this addition the madder reds are rendered more beautiful, and the fawn colour, or brownish-yellow hue, which injures these colours, would be thus overcome.[1]

Sect. II.—*Of Yellow.*

All the yellow dyes, as well as the red, require a mordant to fix them on the cloth; and the usual mordant employed is alumina. As in the last section, we shall in the first place give an account of the dyestuffs usually employed for giving a yellow colour to cloth, and then give a sketch of the methods employed for giving a yellow colour to wool, silk, cotton, and linen.

I.—*Description of the Dyestuffs.*

The principal colouring matters used in dyeing yellow are *weld*, *fustic*, *catechu*, *anotta*, and *quercitron*. We shall give a short account of these dyestuffs in succession.

Substances employed in dyeing yellow. Weld. 1. *Weld*, in French *gaud* or *vaud*, is the dried leaves and stems of the *reseda luteola*, a plant which grows wild in Britain, and in different European countries. Its leaves are long, narrow, and of a bright green, but the whole plant is made use of in the dyeing of yellow. There are two kinds of weld, cultivated and wild, the former of which is deemed more valuable than the latter, as it yields a much greater proportion of colouring matter. When this plant is fully ripe, it is pulled, dried, and bound up in bundles for the use of the dyer. The wild species grows higher and has a stronger stalk than that which is cultivated, by which the one may be readily distinguished from the other.

A decoction of this plant, if strong, has a brownish-yellow colour, and when diluted with water, it acquires a shade of green. The acids render this colour more pale, while alkalies, common salt, and sal ammoniac, render it deeper; and when sufficient quantities of these substances are dissolved in the decoction, a deep-yellow precipitate falls. A solution of alum or of protochloride of tin throws down a fine yellow lake; sulphate of iron occasions a black precipitate, and sulphate of copper a brownish-green precipitate.

Luteolin. Chevreul has discovered in weld a yellow colouring matter, to which he has given the name of *luteolin*. It may be sublimed, and in that case it crystallizes in needles, which are transparent, and have a pale-yellow colour. Luteolin dissolves in water, but the solution has little colour; yet silk or woollen previously impregnated with alumina, if passed through it, acquires a fine yellow colour. It is soluble in alcohol and ether. It combines with acids, but still more readily with bases. The compound which it forms with potash has a golden-yellow colour; but when exposed to the air it assumes first a shade of green, and then passes into brown. The compounds of luteolin with the other bases are easily obtained by double decomposition.

The yellow colour communicated by weld is more permanent than that communicated by quercitron or by old fustic.

Fustic. 2. *Fustic*[2] is the name given by the dyers in Great Britain to the wood of the *morus tinctoria*, a tree which grows in the West Indies, and probably also in South America. In France it is distinguished by the name of *bois jaune*. The wood is yellow, as its name imports, with orange veins. Ever since the discovery of America it has been used in dyeing, as appears from a paper in the Transactions of the Royal Society, of which Sir William Petty was the author. Its price is moderate, the colour it imparts is permanent, and it readily combines with indigo, which properties give it a claim to attention as a valuable ingredient in dyeing. Before it can be employed as a dyestuff, it must be cut into chips and put into a bag, that it may not fix in, and tear the stuff, to which it is to impart its colouring matter.

Properties. When a decoction of yellow wood or fustic is made very strong, the colour is of a reddish yellow, and when diluted it is of an orange yellow, which it readily yields to water. It becomes turbid by means of acids, its colour is of a pale yellow, and the greenish precipitate may be re-dissolved by alkalies. The sulphates of zinc, iron, and copper, as well as alum, throw down precipitates composed of the colouring matter and the different bases of the salts employed.

Morin. Chevreul discovered in fustic a yellow uncrystallizable colouring matter, to which he has given the name of *morin*. It restores the colour of turmeric paper reddened by lime. It is but little soluble in water, even when boiling hot. Alcohol is a better solvent of it than water, and ether still better than alcohol. When the alcoholic or ether solutions are evaporated, they deposite yellow crystals. The aqueous solution is rendered muddy by gelatine. The solutions of the fixed alkalies and alkaline earths give the aqueous solution a fine yellow colour,

[1] *Philosophy of Permanent Colours*, 317.

[2] The origin of the word *fustic* is not very well understood. The French applied the term *Fustet* to the *rhus cotinus* or *Venice sumach*, which yields fugitive and bad yellow. Bancroft supposes that *fustic* is merely a corruption of the word *fustet*. When the morus tinctoria was introduced, about a couple of centuries ago, being the wood of a large tree, it was called *old fustic*, while the rhus cotinus, being only a shrub, was called *young fustic*. Rhus cotinus being now hardly used by dyers, the term fustic has been assigned to the wood of the morus tinctoria.

Simple Colours.

without occasioning any precipitate. Alum causes it to assume a greenish-yellow colour. The sulphated peroxide of iron renders it green, and then throws down a precipitate. Concentrated sulphuric acid increases the intensity of the yellow colour, while nitric acid gives it a reddish shade, and renders it muddy. Boiling nitric acid converts it into oxalic acid. By combining with oxygen it seems to assume a red colour. Morin, when distilled, yields a liquid, which crystallizes as it cools, and furnishes a number of yellowish-brown needles. According to the experiments of George, boiling water extracts from fustic 0·15, and alcohol 0·09 of matter; and the wood is composed of

Lignin	74
Morin	9·1
Tannin	4
Gum	2
Resin	9
	98·1

3. *Catechu*, or *terra japonica*, comes from the East Indies, and is the inspissated decoction of certain plants containing tannin, but principally of the *areka nut*, the wood of *mimosa catechu*, the leaves of the *nauclea catechu*. Areka nuts, cut into small pieces, are sprinkled in an earthen vessel with water holding saltpetre in solution. A portion of the bark of kantai-babela (a species of mimosa) is added. The vessel is closed by a lid luted down with clay, that the temperature may be the higher. After an ebullition of two hours, the fire is gradually diminished during five or six hours. When the vessel is cold the areka nuts are taken out, and the decoction is evaporated down to the consistency of a syrup. It is then kneaded into small balls, and left to dry in the shade.

Constituents.

The principal constituents of catechu are tannin and extractive. The former may be thrown down by gelatine, the latter remains in solution. It has a reddish-brown colour and a sweetish taste. In India catechu is employed in dyeing and calico-printing. The colours which it gives are very various, depending upon the nature of the mordants employed along with it; but they are all very fixed. With verdigris and sal ammoniac the colour is brown; with protochloride of tin yellow; with perchloride of tin a brown, or, if nitrate of copper be added, a deep bronze; with nitrate of alumina a copper red; with nitrate of iron a deep brownish gray.

At the present day catechu is employed in this country both by the dyers and calico-printers, and it is very well entitled to their attention, both on account of its cheapness, and the permanency and variety of the colours which it gives.

4. *Anotta*, in French *rocou*, is a species of paste of a red colour, obtained from the berries of the *bixa orellana*, Lin. which is a native of America. The anotta of commerce is imported from America to Europe in cakes of two or three pounds weight, where it is prepared from the seeds of the tree mentioned above; but the Americans are said to be in possession of a species of anotta superior to that which they export, both for the brilliancy and permanency of the colour it imparts. They bruise the seeds with their hands moistened with oil, separating with a knife the paste as it is formed, and drying it in the sun; but the seeds are pounded with water when designed for sale, and allowed to undergo the process of fermentation.

According to John, the cakes of anotta are composed of twenty-eight parts of resin mixed with colouring matter, twenty parts of coloured extractive, twenty-six of gum, and twenty of lignin, mixed with an acid and an aromatic substance.

The colouring matter of anotta is but little soluble in water, though it communicates a yellow colour to that liquid. It is more soluble in alcohol, and tinges it orange. Ether dissolves it still better, and assumes also an orange colour. We obtain the colouring matter in a sufficiently pure state by evaporating the alcoholic solution to dryness, treating the residue with ether, and finally distilling off the ether. It is a reddish-brown substance, heavier than water, soft and adhesive. Even when exposed to a very low temperature, it does not become brittle. When heated it melts, and when sufficiently heated in an open vessel it takes fire and burns like a resin.

Its colouring matter.

We may likewise obtain the colouring matter of anotta by digesting it in a caustic alkaline solution, and then saturating the alkali by an acid. The colouring matter precipitates in orange flocks. Concentrated sulphuric acid gives anotta an indigo-blue colour; but in contact with air this colour soon passes into green, and then into violet brown. Cold nitric acid does not alter the colour of anotta but if the quantity of acid be small, the mixture assumes the consistence of a syrup, and detonates when slightly heated, leaving charcoal. Anotta gives an orange-red colour to oils, both fixed and volatile.

According to Chevreul, anotta contains two different colouring matters, the one yellow and the other red. The yellow colouring matter is soluble in water and alcohol, and slightly in ether; the red colouring matter is scarcely soluble in water, but it dissolves in alcohol and ether, communicating to these liquids an orange-red colour.

Anotta yields an orange precipitate with a solution of alum, and the sulphates of copper and iron produce effects of nearly a similar nature. With a solution of tin the precipitate is of a lemon colour, and slowly deposited.

It is employed both for dyeing silk and cotton, but the colours which it yields have little permanency.

Quercitron bark.

5. *Quercitron bark.*—Quercitron, as it is denominated by Dr Bancroft, is the *quercus nigra* of Linnæus, and is a large tree which grows spontaneously in North America. The bark of it yields a considerable quantity of colouring matter, which was first discovered by Dr Bancroft in the year 1784, in whom the use and application of it in dyeing were exclusively vested for a certain term of years by virtue of an act of parliament. To prepare it for use, the epidermis is taken off and pounded in a mill, the result of which process is a number of filaments and a fine light powder; but as these do not contain equal quantities of colouring matter, it will be proper to employ them in their natural proportions.

Quercitron bark contains a good deal of tannin, and a yellow colouring matter capable of being extracted by water. The aqueous solution, when evaporated to dryness, leaves a quantity of extract, amounting to eight per cent. of the weight of the bark employed. The tannin is that variety which forms a green precipitate with oxide of iron. Its presence is injurious to the beauty of the yellow colour, because it is precipitated by the same re-agents as the colouring matter itself, and of course communicates to it a shade of brown. To free the colouring matter from tannin, ox bladder steeped in water, and deprived of every thing soluble in cold water, is introduced into the quercitron infusion. With this substance the tannin gradually unites, and thus is removed from the solution. It may be thrown down also by a solution of gelatine.

When the infusion of quercitron is gently concentrated, the colouring matter is deposited in crystals, which have a pearly lustre as long as they continue suspended in the liquid. To this colouring matter Chevreul has given the name of *quercitrin*. It restores the yellow colour of turmeric paper reddened by an alkali. It is but little soluble in ether, more soluble in alcohol, and still more soluble in water. The aqueous solution is tinged orange by al-

Simple Colours.

kalies. The acetates of lead and copper, and the protochloride of tin, throw it down in yellow flocks. The sulphated peroxide of iron gives it an olive-green colour, and then precipitates it. Sulphuric acid dissolves quercitrin, the solution is orange with a shade of green, and is rendered muddy when mixed with water. When quercitrin is subjected to distillation, it yields, among other products, a liquid which speedily deposites yellow crystals possessing the characters of quercitrin.

Other substances.

Besides the substances already mentioned as employed in the dyeing of yellow, we may add saw-wort to the number (*serratula tinctoria*, Lin.), a plant which yields a colouring matter nearly similar to that of weld, and may of consequence be used as a proper substitute. Dyers' broom (*genista tinctoria*) produces a yellow of very indifferent nature, and is therefore only employed in dyeing stuffs of the coarsest kind. Tumeric (*curcuma longa*) is a native production both of the East and West Indies, and yields a more copious quantity of colouring matter than any other yellow dyestuff; but it will probably never be of any essential service in dyeing yellow, as no mordant has yet been discovered capable of giving permanency to its colour.

Chamomile (*anthemis tinctoria*) yields a faint yellow colour, the hue of which is not unpleasant, but is far from being durable, and even mordants are not capable of fixing it. Sulphate of lime, tartar, and alum, bid fairest for success.

Fenugreek (*trigonella fænugræcum*) yields seeds which, when ground, communicate to stuffs a pale yellow of tolerable durability; and the best mordants are found to be alum and muriate of soda, or common salt. American hiccory (*juglans alba*) is a tree, the bark of which yields a colouring matter in every respect resembling that of the *quercus nigra*, but in quantity greatly inferior. French berries (*rhamnus infectorius*) produce a tolerable yellow colour, but it is by no means permanent. When used in the process of dyeing, they are to be employed in the same manner as weld. According to Scheffer, a fine yellow colour may be imparted to silk, thread, and wool, by means of the leaves of the willow; but Bergman informs us that only the leaves of the sweet willow (*salix pentandra*) are proper for producing a permanent colour, as a few weeks' exposure to the sun extracts that which is produced by the colouring matter from the leaves of the common willow.

In Switzerland and in England the seeds of purple trefoil are sometimes employed in the art of dyeing, on which Vogler made a number of experiments, in order to ascertain what colours they would produce; and he found that a fine deep yellow was afforded by a bath made of a solution of these seeds with potash; that sulphuric acid yielded a light yellow, and sulphate of copper or blue vitriol a yellow inclining to green. M. Dizé informs us that the seeds of trefoil impart to wool a beautiful orange, and to silk a greenish yellow; and that while aluming is necessary in the process of dyeing with the seeds of trefoil, a solution of tin cannot be employed.

Many other vegetable substances are occasionally employed in dyeing yellow, but it seems useless to enumerate them. Saffron and turmeric yield exceedingly beautiful but fugitive yellows. The colouring matter of saffron (*crocus sativus*) is extremely rich; it has been subjected to a chemical examination, and distinguished by the name of *polychroite* by Bouillon La Grange and Vogler, to whom we are indebted for the first examination of it.

The finest and most fixed of all the yellows on cotton is chromate of lead. It is employed abundantly by the calico-printers, but scarcely by the dyers in general. On that account we think it better to reserve it till we come to that part of this article in which we propose to describe the processes followed by the calico-printers.

II.—*Of the Processes for dyeing Wool Yellow.*

With weld.

In dyeing woollen stuffs with weld, the mordants employed are alum and tartar, and by their means a pure, permanent yellow is obtained. The boiling is to be conducted in the usual way; and, according to Hellot, four ounces of alum to one ounce of tartar are to be employed. Other dyers, however, employ half as much tartar as alum. The colour is rendered paler, but more lively, by means of the tartar.

Preparation of the bath.

The bath is prepared by boiling the plant inclosed in a thin linen bag, and keeping it from rising by means of a wooden cross. Some boil it till it sinks to the bottom of the vessel; while others, after it is boiled, take it out and throw it away. From three to four pounds of weld, and sometimes less, are allowed for every pound of stuff; but the quantity must be regulated by the intensity of the shade desired. Some dyers add a small quantity of quicklime and ashes which are found to promote the extraction of the colouring matter. These substances at the same time heighten the colour, but render it less susceptible of resisting the action of acids.

For different shades

With other additions, and different management, different shades may be obtained. Thus lighter shades are produced by dyeing after deeper ones, adding water at each dipping, and keeping the bath at the boiling temperature. These shades, however, are less lively than when fresh baths are employed, with a suitable proportion of weld. The addition of common salt or sulphate of lime to the weld bath communicates a richer and deeper colour. With alum it is paler and more lively, with tartar still paler, and with sulphate of iron the shade inclines to brown. According to Scheffer, by boiling the stuff two hours, with one fourth of its weight of a solution of tin, and the same proportion of tartar, and then washing and boiling it with an equal weight of weld, a fine yellow is produced; but if the stuff be in the state of cloth, its internal texture is not penetrated. Poerner recommends a similar preparation as for dyeing scarlet, and by these means the colour is brighter, more permanent, and lighter.

With quercitron bark.

Dr Bancroft recommends the quercitron bark as one of the cheapest and best substances for dyeing wool yellow. The following is the simple process which he has proposed for its application. The bark is to be boiled up with about its weight, or one third more, of alum, in a suitable proportion of water, for about ten minutes. The stuff previously scoured is then to be immersed in the bath, taking care to give the higher colours first, and afterwards the paler straw colours. By this cheap and expeditious process, colours which are not wanted to be of a full or bright yellow may be obtained. The colour may be considerably heightened by passing the unrinsed stuff a few times through hot water, to which a little clean powdered chalk, in the proportion of about a pound and a half for each 100 lbs. of stuff, has been previously added. The bark, when used in dyeing, being first reduced to powder, should be tied up in a thin linen bag, and suspended in the liquor, so that it may be occasionally moved through it, to diffuse the colouring matter more equally.

Process for permanent colours.

But although the above method possesses the advantages of cheapness and expedition, and is fully sufficient for communicating pale yellows; to obtain fuller and more permanent colours, the common mode of preparation, by previously applying the aluminous mordant, ought to be preferred. The stuff, therefore, should be boiled for about one hour or one hour and a quarter, with one sixth or one eighth of its weight of alum dissolved in a proper pro-

Simple Colours.

portion of water. The stuff is then to be immersed, without being rinsed, into the dyeing bath, with clean hot water, and about the same quantity of powdered bark tied up in a bag as that of the alum employed in the preparation. The stuff is then to be turned as usual through the boiling liquor, until the colour appears to have acquired sufficient intensity. One pound of clean powdered chalk for every 100 lbs. of stuff is then to be mixed with the dyeing bath, and the operation continued for eight or ten minutes longer. This addition of the chalk raises and brightens the colour.

For different shades.

Orange Yellow.—To communicate a beautiful orange yellow to woollen stuffs, ten lbs. of quercitron bark, tied up in a bag, for every 100 lbs. of stuff, are to be put into the bath with hot water. At the end of six or eight minutes, an equal weight of murio-sulphate of tin is to be added, and the mixture well stirred for two or three minutes. The cloth, previously scoured, and completely wetted, is then immersed in the dyeing liquor, and briskly turned for a few minutes. By this process the colouring matter fixes on the cloth so quickly and equally, that after the liquor begins to boil, the highest yellow may be produced in less than fifteen minutes.

High shades of yellow, somewhat similar to those obtained from quercitron bark by the above process, are frequently given with young fustic (*rhus cotinus*, Lin.), and dyers' spirit, or nitro-muriate of tin; but this colour is much less beautiful and permanent, while it is more expensive, than what is obtained from the bark.

Bright Golden Yellow.—This colour is produced by employing ten pounds of bark for every 100 pounds of cloth, the bark being first boiled a few minutes, and then adding seven or eight pounds of murio-sulphate of tin, with about five pounds of alum. The cloth is to be dyed in the same manner as in the process for the orange yellow.

Bright yellows of less body are produced by employing a smaller proportion of bark, as well as by diminishing the quantity of murio-sulphate of tin and alum. And indeed every variety of shade of pure bright yellow may be given by varying the proportions of the ingredients.

For greenish yellow.

To produce the lively delicate green shade, which, for certain purposes, is greatly admired, the addition of tartar, with the other ingredients, only is necessary, and the tartar must be added in different proportions, according to the shade which is wanted. For a full bright yellow, delicately inclining to the greenish tinge, it will be proper to employ eight pounds of bark, six of murio-sulphate of tin, with six of alum, and four of tartar. An additional proportion of alum and tartar renders the yellow more delicate, and inclines it more to the green shade; but when this lively green shade is wanted in the greatest perfection, the ingredients must be used in equal proportions. The delicate green lemon yellows are seldom required to have much fulness or body. Ten pounds of bark, therefore, with an equal quantity of the other ingredients, are sufficient to dye three or four hundred pounds of stuffs.[1]

For pale green yellow.

To produce the exquisitely delicate and beautiful pale green shades, the surest method, Dr Bancroft observes, is to boil the bark with a small proportion of water, in a separate tin vessel, for six or eight minutes, and then to add the murio-sulphate of tin, alum, and tartar, and to boil them together for about fifteen minutes. A small quantity of this yellow liquor is then to be put into a dyeing vessel which has been previously supplied with water sufficiently heated. The mixture being properly stirred, the dyeing process is to be conducted in the usual way, and the yellow liquor, as it is wanted, gradually added from the first vessel. In this way the most delicate shades of lively green lemon yellows are dyed with ease and certainty. Weld is the only dyestuff from which similar shades of colour can be obtained; but it is four times more expensive. The yellows dyed from quercitron bark, Dr Bancroft adds, with murio-sulphate of tin and alum as mordants, do not exceed the expense of one penny for each pound of stuff, besides a considerable saving of time, labour, and fuel.[2]

Verdigris used for tartar.

A greenish shade may also be produced without tartar, by substituting verdigris dissolved in vinegar, along with the bark; but it is neither so permanent, nor so bright and delicate, as that produced by means of tartar. Sulphate of indigo also, in very small proportion, communicates a similar shade when it is employed with the bark, murio-sulphate of tin, and alum; but it is apt to take unequally on the stuff, and besides, in the language of the dyers, the colour has a tendency to *cast* or *fly* in the finishing.

Cochineal and madder employed.

Small proportions of cochineal, employed along with the bark and other ingredients, raise the colour to a beautiful orange, and even to an aurora. Madder may be also employed with the same view, for it heightens the yellow obtained from quercitron bark, although the colour thus obtained is inferior in beauty to that from cochineal. The madder may also be employed with weld for the same purpose.[3]

Colours from quercitron bark very durable.

The colours obtained from quercitron bark, by the processes which we have now described, are very durable. They resist the action of the air, of soap, and of acids. It is by the effects of alum, but especially of tartar, that these colours become so fixed as to remain permanent by exposure to the air. It is observed of the highest yellows, even when they approach to the orange, and which are best dyed either with muriate or murio-sulphate of tin and bark, that although they resist the action of soap and acids, they are apt to lose their lustre and become brown by the effect of the sun and air; but this also happens to yellows dyed with nitro-muriate of tin, both with the bark and with weld, but in a still greater degree with other yellow vegetable colouring matters. In some of these this defect is less easily obviated by alum and tartar, than it is in the yellow obtained from weld and quercitron bark.[4]

III.—*Of the Processes for dyeing Silk Yellow.*

With weld.

To dye silk a plain yellow colour, the only ingredient which was formerly employed was weld. The following is the process. The silk being previously scoured in the proportion of twenty pounds of soap to the hundred of stuff, and then alumed, and washed after the aluming, or, as it is called, *refreshed*, the bath is prepared with two pounds of weld for every pound of silk; and having boiled for fifteen minutes, it is to be passed into a vat through a sieve or cloth. When the temperature is such as the hand can bear, the silk is introduced and turned until it has acquired a uniform colour. While this operation is going on, the weld is to be boiled a second time in fresh water; one half of the first bath is taken out, and its place supplied with a fresh decoction. The temperature of the fresh bath may be a little higher than the former; but it is necessary to guard against too great a degree of heat, that the colouring matter already fixed may not be dissolved. The stuff is to be turned as before, and afterwards taken out of the bath. A quantity of soda is to be dissolved in a part of the second decoction, and a larger or smaller proportion of this solution is to be added to the

[1] Bancroft, 330. [2] *Ibid.* 333. [3] *Ibid.* 355. [4] *Ibid.* 334.

Simple Colours.

bath, according to the intensity of the shade required. When the silk has been turned a few times, a skain is wrung out, that it may be examined whether the colour be sufficiently full, and have the proper golden shade. To render the colour deeper, and to give it the gold cast, an addition of the alkaline solution is to be made to the bath, and to be repeated till the shade has acquired sufficient intensity. The alkaline solution may also be added along with the second decoction of the weld, observing the precaution that the temperature of the bath be never too great.

For a deeper colour.

For other shades.

To produce other shades of yellow, having more of a gold or jonquille colour, a quantity of anotta, proportioned to the shade required, is to be added to the bath along with the alkali. Lighter shades of yellow, such as pale lemon or Canary bird colour, are obtained by previously whitening the silk, and regulating the proportion of ingredients in the bath by the shade required. To communicate a yellow having a tinge of green, a little indigo is added to the bath, if the silk has not been previously azured. To prevent the intensity of the shade from being too great, the silk may be more slightly alumed than usual.

A cheaper process.

But, according to Dr Bancroft, the different shades of yellow obtained from weld may be given to silk with equal facility and beauty, and at a cheaper rate, by employing quercitron bark as a substitute. A quantity of bark powdered and enclosed in a bag, in proportion to the shade of colour wanted, as from one to two pounds for every twelve pounds of silk, is put into the dyeing vat while the water is cold. Heat is then applied; and when it has become rather more than blood warm, or of the temperature of 100°, the silk, having previously undergone the aluming process, is to be immersed and dyed in the usual way. If a deep shade is wanted, a small quantity of chalk or pearl-ashes may be added towards the end of the operation. To produce a more lively yellow, a small proportion of murio-sulphate of tin may be employed; but it should be cautiously used, as it is apt to diminish the lustre of the silk. To produce such a shade, the proportions of the ingredients may be four pounds of bark, three of alum, and two of murio-sulphate of tin. These are to be boiled with a proper quantity of water for ten or fifteen minutes; and the temperature of the liquid being so much reduced as the hand can bear it, the silk is immersed and dyed as usual, till it has acquired the proper colour. Care should be taken to keep the liquor constantly agitated, that the colouring matter may be equally diffused.[1]

For an orange colour.

To dye silk of an aurora or orange colour, after being properly scoured, it may be immersed in an alkaline solution of anotta, the strength of which is to be regulated by the shade required; and the temperature of the bath should be between tepid and boiling water. When the desired shade has been obtained, the silks are to be washed and twice beetled, to free them from the superfluous colouring matter, which would injure the beauty of the colour. When raw silk is to be dyed, that which is naturally white should be selected, and the bath should be nearly cold; for otherwise the alkali, by dissolving the gum of the silk, destroys its elasticity. Silk is dyed of an orange shade with anotta; but the stuffs must be reddened with vinegar, alum, or lemon juice. The acid, by saturating the alkali employed to dissolve the anotta, destroys the yellow shade produced by the alkali, and restores its natural colour, which inclines to a red. But although beautiful colours are obtained by this process, they do not possess any great degree of permanency.

Yellow dye from mushrooms.

Several kinds of mushrooms afford lively and durable yellow dyes. A bright shining dye of this description has been extracted from the *boletus hirsutus*, which commonly grows on walnut and apple trees. The colouring matter is contained both in the tubular part, and also in the parenchyma of the body of the mushroom. To extract the colouring matter, it is pounded in a mortar, and the liquor which is thus obtained is boiled for a quarter of an hour in water. An ounce of liquor is sufficient to communicate colouring matter to six pounds of water. After the liquor has been strained, the stuff to be dyed is immersed in it, and boiled for fifteen minutes. When silk is subjected to this process, after being dyed, it is made to pass through a bath of soft soap, by which it acquires a shining golden yellow colour, which has a near resemblance to the yellow of the silk employed to imitate embroidery in gold. This has been hitherto brought from China, and bears a very high price, the method of dyeing it being unknown in Europe. All kinds of stuff receive this colour; but it is less bright on linen and cotton, and seems to have the strongest affinity for silk. The use of mordants, it is supposed, would modify and improve it greatly.[2]

IV.—*Of the Processes for dyeing Cotton and Linen Yellow.*

Processes with weld.

The process which has been usually followed in dyeing cotton and linen yellow, is by scouring it in a bath prepared in a ley with the ashes of green wood. It is afterwards washed, dried, and alumed, with one fourth of its weight of alum. After twenty-four hours it is taken out of the aluming and dried, but without being washed. The cotton is then dyed in a weld bath, in the proportion of one pound and a quarter of weld for each pound of cotton, and turned in the bath till it has acquired the proper colour. After being taken out of the bath, it is soaked for an hour and a half in a solution of blue vitriol (sulphate of copper), in the proportion of one fourth of the weight of the cotton, and then immersed, without washing, for nearly an hour in a boiling solution of white soap, after which it is well washed and dried.

For a deeper yellow,

A deeper yellow is communicated to cotton by omitting the process of aluming, and employing two pounds and a half of weld for each pound of cotton. To this is added a dram of verdigris, mixed with part of the bath. The cotton is then to be dipped and worked till the colour become uniform It is then taken out of the bath, that a little solution of soda may be added, after which it is returned and kept for fifteen minutes. It is then wrung out and dried.

and other shades.

Other shades of yellow may be obtained by varying the proportion of ingredients. Thus a lemon colour is dyed by using only one pound of weld for every pound of cotton, and by diminishing the proportion of verdigris, or using alum as a substitute.[3]

Cheaper and more permanent colours.

But a better method, as it affords more permanent and more beautiful colours, and at a smaller expense, is recommended by Dr Bancroft. This is by the use of quercitron bark, and the calico-printers' aluminous mordant, or the sugar of lead. The following is the process which he proposes to employ for producing bright and durable yellow colours. One pound of sugar of lead and three pounds of alum are to be dissolved in a sufficient quantity of warm water. The cotton or linen, after being properly rinsed, is to be soaked in this mixture, heated to the temperature of 100°, for two hours. It is then taken out, moderately pressed over a vessel, to prevent the waste of the aluminous liquor. It is then dried in a stove heat, and after being again soaked in the aluminous solution, it is wrung

[1] Bancroft, 345.

[2] *Philosophical Magazine*, vol. 100.

[3] Berthollet, ii. 267.

Simple Colours.

out and dried a second time. Without being rinsed, it is to be barely wetted with lime water, and afterwards dried; and if a full, bright, and durable yellow is wanted, it may be necessary to soak the stuff in the diluted aluminous mordant, and, after drying, to wet it a second time with lime water. After it has been soaked for the last time, it should be well rinsed in clean water, to separate the loose particles of the mordant, which might injure the application of the colouring matter. By the use of the lime-water, a greater proportion of alumina combines with the stuff, besides the addition of a certain proportion of lime.

Dyeing bath.

In the preparation of the dyeing bath, from twelve to eighteen pounds of powdered quercitron bark are inclosed in a bag for every hundred pounds of the stuff, varying the proportion according to the intensity of the shade desired. The bark is put into the water while it is cold; and immediately after, the stuff is immersed and agitated or turned for an hour or an hour and a half, during which the water should be gradually heated, and the temperature raised to about 120°. At the end of this time the heat is increased, and the dyeing liquor brought to a boiling temperature; but at this temperature the stuff must remain in it only for a few minutes, because otherwise the yellow assumes a brownish shade. The stuff having thus acquired a sufficient colour, is taken out, rinsed, and dried.

Advantage of a diluted mordant.

Dr Bancroft observes, that when the aluminous mordant is employed without the addition of water, one soaking only, and an immersion in lime water, may be sufficient; but he thinks that greater advantage is derived from the application of a more diluted mordant at two different times, or even by the immersion of the stuff a greater number of times, alternately in the diluted aluminous mordant, and lime water, and drying it after each immersion. By this treatment he found that the colour always acquired more body and durability.

Nankeen yellow.

Chaptal has proposed a process for communicating to cotton a nankeen yellow, which, at the same time that it affords a durable colour, has the advantage of being cheap and simple. When cotton is immersed in a solution of any salt of iron, it has so strong an affinity for the oxide, that it decomposes the salt, combines with the iron, and assumes a yellow colour. The process recommended by Chaptal is the following: The cotton to be dyed is put into a cold solution of copperas (sulphate of iron), of the specific gravity 1·02. It is afterwards wrung out, and immediately immersed in a ley of potash of the specific gravity 1·01. This ley must have been previously saturated with a solution of alum. When the stuff has been kept for four or five hours in this bath, it may be taken out, washed, and dried. By varying the proportion of sulphate of iron, every variety of shade of nankeen yellow may be obtained.

By another process.

We shall lay before our readers another process for dyeing nankeen colour, which is proposed and followed by Mr Brewer, a practical dyer. It is as follows:—

"Mix as much sheep's dung in clear water as will make it appear of the colour of grass; and dissolve in clear water one pound of best white soap for every ten pounds of cotton yarn, or in that proportion for a greater or lesser quantity.

"Observe:—The tubs, boards, and poles, that are used in the following preparations must be made of deal; the boiling pan of either iron or copper.

First operation.—"Pour the soap liquor prepared as above into the boiling pan; strain the dung liquor through a sieve; add as much thereof to the soap liquor in the pan as will be sufficient to boil the yarn intended to be dyed, for five hours. When the liquors are well mixed in the pan, enter the yarn, light the fire under the pan, and bring the liquor to boil in about two hours, observing to increase the heat regularly during that period. Continue it boiling for three hours; then take the yarn out of the pan, wash it, wring it, and hang it in a shed on poles to dry. When dry, take it into a stove or other room where there is a fire; let it hang there until it be thoroughly dry.

N. B.—"The cotton yarn, when in the shed, should not be exposed either to the rain or sun. If it is, it will be unequally coloured when dyed.

Second operation.—"In this operation use only one half of the soap that was used in the last, and as much dung liquor (strained as before directed) as will be sufficient to cover the cotton yarn, when in the pan, about two inches. When these liquors are well mixed in the pan, enter the yarn, light the fire, and bring the liquor to boil in about one hour; then take the yarn out, wring it out without washing, and hang it to dry, as in the former operation.

Third operation.—"This operation the same as the second in every respect.

Fourth operation.—"For every ten pounds of yarn make a clear ley from half a pound of pot or pearl ashes. Pour the ley into the boiling pan, and add as much clear water as will be sufficient to boil the yarn for two hours; then enter the yarn, light the fire, and bring it to boil in about an hour. Continue it boiling about an hour, then take the yarn out, wash it very well in clear water, wring it, and hang it to dry, as in former operations.

N. B.—"This operation is to cleanse the yarn from any oleaginous matter that may remain in it after boiling in the soap and dung liquors.

Fifth operation.—"To every gallon of iron liquor[1] add half a pound of ruddle or red chalk (the last the best) well pulverized.

"Mix them well together, and let the liquor stand four hours, in order that the heavy particles may subside; then pour the clear liquor into the boiling-pan, and bring it to such a degree of heat as a person can well bear his hand in; divide the yarn into small parcels, about five hanks in each; soak each parcel or handful very well in the above liquor, wring it, and lay it down on a clean deal board. When all the yarn is handed through the liquor, the last handful must be taken up and soaked in the liquor a second time, and every other handful in succession, till the whole is gone through; then lay the yarn down in a tub, wherein there must be put a sufficient quantity of ley, made from pot or pearl ashes, as will cover it about six inches. Let it lie in this state about two hours, then hand it over in the ley, wring it, and lay it down on a clean board. If it does not appear sufficiently deep in colour, this operation must be repeated till it has acquired a sufficient degree of darkness of colour. This done, it must be hung to dry, as in former operations.

N. B.—"Any degree of red or yellow hue may be given to the yarn, by increasing or diminishing the quantity of ruddle or red chalk.

Sixth operation.—"For every ten pounds of yarn make a ley from half a pound of pot or pearl ashes; pour the clear ley into the boiling pan; add a sufficient quantity of water thereto, that will cover the yarn about four inches; light the fire, and enter the yarn when the liquor is a little warm; observe to keep it constantly under the liquor for two hours; increase the heat regularly till it come to a scald; then take the yarn out, wash it, and hang it to dry, as in former operations.

[1] Iron liquor is what the linen printers use.

Seventh operation.—" Make a sour liquor of oil of vitriol and water. The degree of acidity may be a little less than the juice of lemons; lay the yarn in it for about an hour, then take it out, wash it very well, and wring it; give it a second washing and wringing, and lay it upon a board.

N. B.—" This operation is to dissolve the metallic particles, and remove the ferruginous matter that remains on the surface of the thread after the fifth operation.

Eighth operation.—" For every ten pounds of yarn dissolve one pound of best white soap in clear water, and add as much water to this liquor in your boiling-pan as will be sufficient to boil the yarn for two hours. When these liquors are well mixed, light the fire, enter the yarn, and bring the liquor to boil in about an hour. Continue it boiling slowly an hour; take it out, wash it in clear water very well, and hang it to dry, as in former operations. When dry, it is ready for the weaver.

N. B.—" It appears to me, from experiments that I have made, that less than four operations in the preparation of the yarn will not be sufficient to cleanse the pores of the fibres of the cotton, and render the colour permanent."[1]

Process followed in the East.

A method of giving a very fixed yellow to cotton and linen is practised in the East. It is precisely similar to the plan followed in dyeing Turkey red. The cloth is first impregnated with the oleaginous soap. It is then passed through a decoction of nutgalls, or of some substance containing tannin. The aluminous mordant is then applied. After all these preliminary steps have been accomplished, the cloth is dyed in the usual way with quercitron bark. These complicated processes being precisely similar to those followed by the Turkey-red dyers, we refer the reader for particulars to the fourth division of the first section of the present chapter.

Such processes, however, are unnecessary in this country, because as permanent and beautiful a colour can be given at once to cotton by impregnating it with acetate or nitrate of lead, and then passing the cloth through a solution of bichromate of potash.

Sect. III.—*Of Blue.*

We shall follow the same method in giving an account of the blue dye, as we did when giving an account of the red and yellow dyes; that is to say, we shall first notice the dyestuffs, and then describe the processes followed by the dyers.

I.—*Description of the Dyestuffs.*

The only dyestuff used for giving a blue colour to cloth is *indigo*, a blue pigment obtained from various species of plants. The most common plant yielding indigo is the *Indigofera*, of which there are three species, the *tinctoria*, the *disperma*, and the *argentea*. The *nerium tinctorium*, or rose bay, a tree which is a native of India, also yields it. The method of procuring indigo from these plants, the nature and properties of indigo, and its composition, have been detailed in the article Chemistry in this Encyclopædia, to which therefore we refer the reader.

Constituents of indigo.

Mr Crum has shown that the atomic constituents of indigo are,

16 atoms carbon	12
4 atoms hydrogen	0·5
1 atom azote	1·75
2 atoms oxygen	2
	16·25

Indigo in its perfect state is insoluble in water and alcohol, and has not the property of combining with bases. But when deprived of one atom of oxygen, it assumes a yellow colour, and in that state is capable of combining with lime or potash, and doubtless with other bases, and of forming with them compounds which dissolve in water. When cloth to be dyed is dipt into the indigo vat, rendered soluble by being deprived of an atom of oxygen, and united to a base, it comes out stained yellow. But the basis of the indigo begins immediately to attract oxygen from the atmosphere, and to resume its blue colour. This causes the cloth speedily to become *green* by the mixture of yellow and blue, and finally to assume a deep-blue colour. No mordant is necessary, as there is a strong affinity between indigo and the fibres of the cloth.

Cerulin.

When indigo is digested in concentrated sulphuric acid it undergoes a remarkable change, being converted into a peculiar blue substance, with which the Saxon blue is dyed. To this substance Mr Crum, to whom we are indebted for the first accurate examination of it, has given the name of *cerulin.* Mr Crum has shown that it is a compound of one integrant particle of indigo, and four integrant particles of water.

The mixture of cerulin with sulphuric acid is semifluid, which requires a considerable quantity of water to dissolve it. When potash is added to this solution, a deep-blue precipitate falls, which is a compound of sulphate of potash and cerulin. To this compound Mr Crum has given the name of cerulio-sulphate of potash. All the neutral salts have the property of combining with cerulin, and of precipitating it from its aqueous solution.

Phenicin.

Mr Crum discovered that if the action of sulphuric acid on indigo be stopped at a certain point, a new substance is formed, different from cerulin. To this new substance he gave the name of *phenicin.* It may be obtained by the following process: Digest indigo in sulphuric acid diluted with thrice its weight of water. By this process the indigo is deprived of the greater part of its impurities. Mix one part of this purified indigo with seven or eight parts of concentrated sulphuric acid in a stoppered phial, and agitate the mixture occasionally till it becomes of a bottle-green colour. Then mix it with a large quantity of distilled water, and throw it upon a filter. By continuing to wash the filter, the liquid, which at first passes through colourless, becomes more and more blue, and after some time all the indigo which has been changed passes through. The colourless washings must be thrown away. The blue liquid contains the phenicin in solution, which, on the addition of chloride of potassium precipitates of a most beautiful reddish-purple colour, exactly similar to the colour of the vapour of indigo. Its solution is of a fine blue colour like cerulin, but when a neutral salt is added it is precipitated of a fine purple colour. Hence the origin of the term *phenicin.*[2] Mr Crum has shown that it is a compound of one integrant particle of indigo and two integrant particles of water.

Indigo is not confined to plants growing within the torrid zone. The *isatis tinctoria* and *isatis lusitanica*, plants which are cultivated in England and France, yield, when treated in the same way with the leaves of the indigofera, a little indigo; but the quantity is too small to make it worth while to employ these plants for the preparation of this valuable dyestuff. But those plants under the names of *pastel* or *woad* were formerly employed for dyeing blue in all parts of Europe; and it was to prevent any supposed injury to the cultivators of woad that the em-

[1] *Edinburgh Magazine*, xxii.

[2] From φοῖνιξ, *purple.*

Simple Colours.

ployment of indigo in dyeing was prohibited in Queen Elizabeth's time in England. The limitations of the use of indigo in France and Saxony were owing to the same cause. So little at that time were the first principles of political economy understood by the rulers of the different kingdoms of Europe.

Woad is still used by the dyers in some of their processes, but merely for the purpose of de-oxidyzing indigo, and thus rendering it soluble in water.

II.—*Methods of dyeing Wool Blue.*

Preparation of the vat.

The preparation for dyeing blue is made in a large wooden vessel or vat, which should be so constructed as to retain the heat, which is a matter of considerable importance in the process. The vat is therefore set up in a separate place from the coppers, and is sunk so far in the ground as to be only breast-high above it. Before the introduction of indigo, blue was dyed with woad, which furnished a permanent but not a deep colour; but a very rich blue is obtained by mixing indigo with the woad, and these are almost the only substances which are now employed for dyeing woollen stuffs. The proportions of these substances are varied by different dyers, and according to the shade which is required. The following is the account of the preparation of a vat, as it is given by Quatremere. Into a vat of about seven and a half feet deep, and five and a half in diameter, are thrown two balls of pastel or woad, which are previously broken, and together amount to about 400 pounds weight; thirty pounds of weld are boiled in a copper for three hours in a sufficient quantity of water to fill the vat. To this decoction are added twenty pounds of madder and a basket full of bran. The boiling is then continued half an hour longer. This bath is cooled with twenty buckets of water, and after it is settled, and the weld taken out, it is poured into the vat, which must be stirred with a rake all the time that it is running in, and for fifteen minutes longer. The vat is then covered up very hot, and allowed to stand for six hours, when it is uncovered, and raked again for thirty minutes. The same operation must be repeated every three hours. When the appearance of blue streaks is perceived on the surface of the vat, eight or nine pounds of quicklime are added; the colour then becomes of a deeper blue, and the vat exhales more pungent vapours. Immediately after the lime, or along with it, the indigo, which has been previously ground in a mill, with the smallest possible quantity of water, is put into the vat. The quantity is to be regulated by the intensity of the shade required. From ten to thirty pounds may be put into a vat such as we have now described. If on striking the vat with a rake a fine blue scum arises, no other previous preparation is required than to stir it with the rake twice in the space of six hours, to mix the ingredients completely. Great care should be taken not to expose the vat to the air, except during the time of stirring it. When that operation is finished, it is covered with a wooden lid, on which are spread thick cloths, to retain the heat as much as possible; but after all these precautions, at the end of eight or ten days it is greatly diminished, and is at last entirely dissipated, so that the liquor must be again heated, by pouring the greater part of the liquor of the vat into a copper under which a large fire is made. When the liquor has acquired a sufficient temperature, it is returned into the vat, and carefully covered up.

Accidents to which the vat is liable.

Vats of this description are sometimes liable to accidents. A vat is said to be repelled when, having previously afforded fine shades of blue, it appears black, without any blue streaks; and if it be stirred, the black colour becomes deeper; the vat at the same time exhales, instead of a sweetish smell, a pungent odour; and the stuff dyed in a vat in this state comes out of a dirty gray colour. These effects are ascribed to an excess of lime.

Means of obviating them,

Different means are employed to recover a repelled vat. Some are satisfied with merely reheating it, while others add tartar, bran, urine, or madder. Hellot recommends bran and madder as the best remedy. If the excess of lime be not very great, it is sufficient to leave it at rest five or six hours, putting in a quantity of bran and three or four pounds of madder, which are to be sprinkled on the surface, and then it is to be covered up, and after a certain interval to be tried again. But if the vat has been so far repelled as to afford a blue only when it is cold, it must be left at rest to recover, and sometimes must remain whole days without being stirred with the rake. When it begins to afford a tolerable pattern, the bath must be reheated. In general this revives the fermentation. The addition of bran or madder, or a basket or two of fresh woad, produces the same effect.

and remedying putrefaction.

This vat sometimes runs into the putrefactive process. When this happens, the colour of the vat becomes reddish, the paste rises from the bottom, and a fetid smell is exhaled. This accident is owing to a deficiency of lime, and it must be corrected by adding a fresh quantity. The vat is then to be raked; after two hours more lime is added, and the process of raking again performed. These operations are to be repeated till the vat is recovered.

Precautions in the use of lime.

Nothing requires more attention in treating a vat of this kind than the distribution of the lime, the principal use of which is to moderate the tendency to putrefaction, and to limit the fermentation to that degree which is necessary to deprive the indigo of its oxygen. If too much lime be added, the necessary fermentation is retarded; and if there be too little, the putrefactive process commences.

Dyeing process.

Two hours previous to the dyeing operation, the vat should be raked; and to prevent the stuff coming in contact with the sediment, which would produce inequalities in the colour, a cross of wood is introduced, The stuff is then to be completely wetted with pure water a little heated, and being wrung out, it is dipped into the vat, where it is moved about for a longer or a shorter time, according to the depth of shade required. During this operation, it is taken out occasionally to be exposed to the air, the action of which is necessary to change the green colour of the bath into a blue. Stuffs dyed blue in this manner must be carefully washed, to carry off the loose particles of colouring matter; and when the shade of blue is deep, they ought even to be cleansed by fulling with soap. This operation does not alter the colour.

What happens in vats of this kind is the separation of an atom of oxygen from the indigo by the action of the fermenting wood. The base of the indigo thus evolved unites to the quicklime, and this compound dissolving in the water, forms the dyestuff. The reason why the air must be so cautiously excluded is, that, by reviving the indigo, it precipitates it from the liquid, and thus deprives the vat of its colouring matter.

Instead of woad, and the other ingredients just mentioned, indigo is deprived of an atom of oxygen, and the base of it dissolved in water by a mixture of bran and potash. Orpiment is also occasionally employed, which has the property of absorbing an atom of oxygen from indigo, and rendering it capable of combining with a base, and of dissolving in water.

The indigo vat employed by the calico-printers is formed by mixing the indigo with the requisite quantity of sulphate of iron to reduce it to its base, and of quicklime to combine with the base evolved, and to cause it to dissolve in water. Such vats are made very deep. The surface, in consequence of exposure to the air, has a blue colour, the indigo being revived. But the liquor, at a little dis-

Simple Colours.

tance from the surface, has a yellow colour. This indeed is the case with all indigo vats. The green colour which they exhibit near the surface is merely the consequence of the mixture of revived indigo with the yellow coloured liquid.

Discovery of Saxon blue.

The colour which is obtained by dyeing with a solution of indigo in sulphuric acid is known under the name of *Saxon blue*, because the process was first carried on at Grossenhayn, in Saxony, by Counsellor Barth, who made the discovery about the year 1740. This discovery was for some time kept secret, and the method seems to have been originally very complicated. Alumina, antimony, and some other substances, were previously added to the sulphuric acid. These, however, are now omitted, and the indigo alone is dissolved in the acid.

For woollen stuffs.

To produce a Saxon blue colour on woollen stuffs, they are prepared with alum and tartar; and in proportion to the shade required, the quantity of solution of indigo put into the bath must be regulated. When a deep shade of Saxon blue is wanted, the stuff must be passed different times through vessels containing such a quantity of colouring matter as is sufficient to give light colours. In this way, by repeated applications, the colours become more uniform.

We are not aware that Prussian blue is employed as a dyeing material for wool; but it is used to a considerable extent in calico-printing, and has an exceedingly good effect when skilfully used. We shall notice its employment in a subsequent part of this article.

III.—*Processes for dyeing Silk Blue.*

With indigo.

Silk is dyed blue with indigo alone, without any proportion of woad. The proportion of indigo mentioned in the preparation of the indigo vat, and sometimes a larger proportion, is employed, with six pounds of bran and about twelve ounces of madder. According to Macquer, half a pound of madder for each pound of potash renders the vat greener, and produces a more fixed colour in the silk. When the vat is come to, it should be refreshed with two pounds of potash and three or four ounces of madder, and, after being raked, in the course of four hours it is fit for dyeing. The temperature should be so moderated that the hand may be held in it without uneasiness.

Preparation of the silk.

The silk, after being boiled with soap, in the proportion of thirty pounds of soap to a hundred of silk, and well cleaned by repeated beetlings in a stream of water, must be dyed in small portions, because it is apt to take on an uneven colour. When it has been turned once or oftener in the bath, it is wrung out and exposed to the air, that the green colour may change to a blue. When the change is complete, it is thrown into clear water, and afterwards wrung out. Silk dyed blue should be speedily dried. In damp weather and in winter it is necessary to conduct the drying in a chamber heated by a stove. The silk should be hung on a frame kept constantly in motion. To dye light shades, some dyers employ vats that are somewhat exhausted; but it ought to be observed that the colour thus obtained is less beautiful and less permanent than when fresh vats, containing a smaller quantity of indigo, are employed.

For Turkey blue.

Some addition is required to be made to the indigo, to give silk a deep blue. A previous preparation is necessary, by giving it another colour or ground. For the Turkey blue, which is the deepest, a strong bath of archil is first prepared. Cochineal is also sometimes used instead of archil, for the ground, to render the colour more permanent. A blue is given to silk by means of verdigris and logwood, but it possesses little durability. It might be rendered more permanent by giving it a lighter shade in this bath, then dipping it in a bath of archil, and finally in the indigo vat.

Dyeing raw silk.

When raw silk is to be dyed blue, such as is naturally white should be selected. Being previously soaked in water, it is put into the bath in separate hanks, as already directed for scoured silks; and as raw silk is found to combine more readily with the colouring matter, the scoured silk, when it can be conveniently done, should be first put into the bath. If archil, or any of the other ingredients which have been already mentioned, are required to give more intensity to the colour, the mode of application is the same as that directed for scoured silk.

IV.—*Processes for dyeing Cotton and Linen Blue.*

Preparation of the vat.

For dyeing cotton and linen blue, Pileur d'Apligny recommends a vat containing about 120 gallons. From six to eight pounds of indigo, reduced to powder, are boiled in a ley drawn off from a quantity of lime equal in weight to the indigo, and a quantity of potash double its weight. During the boiling, which is to be continued till the indigo is completely penetrated with the ley, the solution must be constantly stirred, to prevent the indigo from being injured by adhering to the bottom of the vessel.

During this process another quantity of quicklime, equal in weight to the indigo, is to be slaked. Twenty quarts of warm water are added, in which is to be dissolved a quantity of sulphate of iron equal to twice the weight of the lime. The solution being completed, it is poured into the vat, which is previously half filled with water. To this the solution of indigo is added, with that part of the ley which was not employed in the boiling. The vat must now be filled up to within two or three inches of the top. It must be raked twice or thrice a day till it is completely prepared, which is generally the case in forty-eight hours, and sometimes sooner, as it depends on the temperature of the atmosphere. A small proportion of bran, madder, and woad, is recommended by some to be added to such a vat as we have now described.

A simpler process.

The process which is followed at Rouen, and described by Quatremere, is simpler. The vats, which are constructed of a kind of flint, are coated within and without with fine cement, and are arranged in one or more parallel lines. Each vat contains four hogsheads of water. The indigo, to the amount of eighteen or twenty pounds, being macerated for a week in a caustic ley strong enough to bear an egg, is ground in a mill; three hogsheads and a half of water are put into the vat, and afterwards twenty pounds of lime. The lime being thoroughly slaked, the vat is raked, and thirty-six pounds of copperas are added; and when the solution is complete, the ground indigo is poured in through a sieve. It is raked seven or eight times the same day, and after being left at rest for thirty-six hours, it is in a state fit for dyeing.

Process on a larger scale.

In extensive manufactories it is necessary to have vats set at different times. In conducting the process of dyeing, the stuffs are first dipped in the most exhausted vat, and then regularly proceeding from the weakest to the strongest, if they have not previously attained the desired shade. The stuffs should remain in the bath only about five or six minutes, for in that time they combine with all the colouring matter they can take up. After the stuffs have been dipped in a vat, it should not be used again till it has been raked, and has stood at least twenty-four hours, unless it has been lately set, when a shorter period is sufficient.

After the stuffs have been dipped three or four times in a vat, it begins to change. It becomes black, and no blue or copper-coloured streaks are seen on the surface after raking it. It must then be renewed by adding four pounds of copperas with two of quicklime, after which it

Simple Colours.

must be raked twice. In this way a vat may be renewed three or four times; but the additional quantity of ingredients must be diminished as the strength of the vat is exhausted.[1]

Process of Bergman.

A vat which is still more simple and more easily prepared has been recommended by Bergman. The proportion of the ingredients which he has directed to be employed is the following. To three drachms of indigo reduced to powder, three drachms of copperas, and three of lime, add two pints of water. Let it be well raked, and in the course of a few hours it will be in a proper state for dyeing.

Haussmann's.

Haussmann employs a still smaller proportion of indigo. For 3000 lbs. of water he takes thirty-six lbs. of quicklime slaked in 200 lbs. of water, with which the indigo in the proportion of from ten to twenty lbs. well ground is to be mixed. He then dissolves thirty lbs. of copperas in 120 lbs. of hot water. The whole being left at rest for fifteen minutes, the vat is filled, and gently and constantly stirred. When a deeper shade is wanted, and particularly when linen is to be dyed, the proportion of indigo should be greater; but the shade depends very much on the time the stuffs remain in the vat, and the times it has been used. When the vat becomes turbid, the process of dyeing must be interrupted till it has been again raked, and the supernatant liquor become transparent. If the effects of the lime fail, a new quantity, fresh slaked, must be added; and if the iron cease to produce the effect on the indigo, a new portion must be also added, observing the precaution to have a greater quantity of lime than what is necessary to saturate the sulphuric acid. When the indigo seems to be exhausted, fresh portions ground in water are also to be added; the vat is to be raked several times, and allowed to settle, after which it is again fit for use. In this way Mr Haussmann informs us he preserved a vat for the space of two years; and had it not been for the accumulation of sediment, which prevented the stuffs from being immersed to a sufficient depth, it might have been continued in use for a much longer time. It is worth while to add, that Mr Haussmann found that a pattern of cloth dipped in water acidulated with sulphuric acid, immediately after it was taken out of the bath, became of a much deeper blue than a similar pattern exposed to the air, or another dipped in river water.

Another convenient and expeditious vat is mentioned by Bergman and described by Scheffer. Indigo reduced to fine powder, in the proportion of three drachms to a quart, is added to the strong ley of the soap boiler. After a few minutes, when the colouring matter is well penetrated by the ley, six drachms of coloured orpiment are to be added. In a few minutes after the bath has been well raked it becomes green, and the blue streaks appear on the surface. Heat is to be applied, when the operation of dyeing may commence.

The preparation employed for printing cottons is similar to the above bath, excepting in the proportions of orpiment and indigo, which are greater in the former; but these proportions are very different in different manufactories.

English blue.

The colour denominated *English blue* is produced by the solution of indigo in sulphuric acid, to which Bancroft gave the improper name of *sulphate of indigo*. To give silk this colour, it is first to be dyed a light blue; and, when taken out of this bath, it is dipped in hot water, washed in a stream, and left in a bath composed of the sulphate of indigo, to which a little of the solution of tin has been added, until the proper shade is obtained, or the bath is exhausted. Previous to its being put into this bath, it may be dipped in a solution of alum, in which it should remain only a very short time. Silk which has been dyed according to thir process is free from the reddish shade which it derives from the blue vat, as well as from the greenish cast of the Saxon blue.[2]

The sulphate of indigo has been hitherto only applied for the purpose of dyeing wool and silk. The affinity of indigo for vegetable substances is not sufficiently strong to effect the decomposition of the sulphate. It cannot, therefore, be employed with advantage in dyeing cotton and linen.

Sect. IV.—*Of Black.*

Juices of plants.

Though black, considered optically, is not a colour, but the absence of the power of reflecting light, it constitutes a very important colour in the estimation of the dyer.

I.—*Description of the Dyestuffs.*

There are few substances which have the property of producing a permanent black colour without any addition. The juice of some plants produces this effect on cotton and linen. A black colour is obtained from the juice of the *cashew nut*, which will not wash out, and even resists the process of boiling with soap or alkalies. The cashew nut of India is employed for marking linen. That of the West Indies (*anacardium occidentale*, Lin.) also yields a permanent dye, but the colour has a brownish shade. The juice of some other plants, as that of the toxicodendron, or sloes, affords a durable bluish black colour; but these substances cannot be obtained in sufficient quantity, even if they afforded colours equal to those produced by the common processes.

Tan, &c.

The principal substances which are employed to give a black colour are gallnuts, which contain the astringent principle or tan, and the red oxide of iron.[3] These have been described either in a preceding part of this article, or under the article Chemistry, to which therefore we refer the reader. The black colour is produced by the combination of the astringent principle with the oxide of iron, held in solution by an acid, and fixed on the stuff. When the particles are precipitated from the mixture of tan and a solution of iron, they have only a blue colour; but after they are exposed for some time to the air, and moistened with water, the colour becomes deeper, although the blue shade is still perceptible. After the particles are fixed on the stuff, the shade becomes much deeper.

Mordants necessary for black.

Logwood is not to be considered as affording a black dye, but is much employed to give a lustre to black colours. We have already described its nature and properties among the substances from which red colouring matters are obtained.

Black colours are rarely produced by a simple combination between the colouring matter and the stuff, but are usually fixed by means of mordants, as in the case of the black particles which are the result of a combination of

---

[1] Berthollet, ii. 90.

[2] *Ibid.* ii. 319.

[3] Oak bark has been recommended as a substitute for gallnuts in dyeing black, and particularly in dyeing hats; and it is said that the colour thus obtained is fuller, more beautiful and durable, while the operation is easier, and less liable to accident. It was first proposed in the year 1782, by Stephanopoli, a Corsican, and a surgeon in the French army. The examination of the process was referred by the French government to Macquer, who gave a favourable report of it; and afterwards to Berthollet, who gave a different opinion. The process has since been examined, and promises to be more economical and advantageous, especially for dyeing hats. (*Phil. Mag.* vi. 176.)

Simple Colours.

the astringent principle and the oxide of iron, held in solution by an acid. But when the particles are precipitated from the mixture of an astringent and a solution of iron, they have only a blue colour. By being exposed to the air, and moistened with water, the colour becomes deeper, although the blue shade is still perceptible. No fine black colour is ever obtained, unless the stuffs are freely exposed to the air. In dyeing black, therefore, the operations must be conducted at different intervals. Berthollet has observed that black stuffs, when brought in contact with oxygen gas, diminish its volume, so that some portion of it is absorbed.

II.—*Of the Processes for dyeing Woollen Black.*

Must be first dyed blue.

In dyeing woollen stuffs black, if a full and fine deep colour is wanted, it is necessary that they be previously dyed of a deep blue colour. To remove all the particles of colouring matter which happen to be loosely attached to the stuff, it should be washed in a river as soon as it is taken out of the vat, and afterwards cleansed at the fulling mill. After these preliminary processes, the stuffs are ready to receive the black colouring matter. The process of Hellot is the following.

Hellot's process.

For every hundred pounds of stuff, ten pounds of logwood, and ten pounds of galls reduced to powder, are put into a bag, and boiled in a middle-sized copper, with a sufficient quantity of water, for twelve hours. A third of this bath is put into another copper, along with two pounds of verdigris. The stuff is immersed in this bath, and continually stirred for two hours. The bath should be kept hot, but it ought not to boil. At the end of two hours the stuff is taken out, and a similar portion of the bath is put into the copper, with eight pounds of copperas (sulphate of iron). During the solution of the copperas the fire is diminished, and the bath is allowed to cool for half an hour stirring it well the whole time. The remainder of the bath is then to be added, and after making this addition, the bag containing the astringent matters should be strongly pressed, to separate the whole. A quantity of sumach, from fifteen to twenty pounds, is now to be added, and the bath is just raised to the boiling temperature; and when it has given one boil it is to be immediately stopped with a little cold water. A fresh quantity of sulphate of iron, to the amount of two pounds, is then added, and the stuff is kept in it for another hour, after which it is taken out, washed, and aired; it is again put into the copper, and constantly stirred for an hour. It is then carried to the river, well washed, and fulled. To soften the black colour, and make it more firm, another bath is prepared with weld. This is made to boil for a moment, and when it has cooled, the stuff is passed through it. By this process, which is indeed somewhat complicated, a beautiful black colour is produced.

Common process.

But the processes usually followed for dyeing black are more simple. Cloth which has been previously dyed blue is merely boiled in a vat of galls for two hours. It is then kept two hours, but without boiling, in the bath of logwood and sulphate of iron, and afterwards washed and fulled. According to Hellot's process, a bath is to be prepared of a pound and a half of yellow wood, five pounds of logwood, and ten pounds of sumach, which is the proportion of the ingredients for every fifteen yards of deep blue cloth; and the cloth having boiled in this bath for three hours, ten pounds of sulphate of iron are added; the cloth is allowed to remain for two hours longer, when it is taken out to be aired, after which it is again returned to the bath for an hour, and then washed and fulled.

A cheaper process.

When stuffs are to be dyed at a less expense, instead of the blue ground, a brown or root-coloured ground may be substituted. This brown or fawn colour is communicated by means of the root of the walnut tree, or green walnut peels. The stuffs are then to be dyed black, according to some of the processes already described.

Process of the English dyers.

The proportions of the ingredients employed by the English dyers are, for every hundred pounds of cloth previously dyed a deep blue, about five pounds of sulphate of iron, five pounds of galls, and thirty of logwood. The first step in the process is to gall the cloth, after which it is passed through the decoction of logwood, to which the sulphate of iron has been added.

Arbutus used for galls.

The leaves of the *arbutus uva ursi* have been recommended and employed as a substitute for galls. The leaves must be carefully dried, so that the green colour may be preserved. A hundred pounds of wool are boiled with sixteen pounds of sulphate of iron and eight of tartar for two hours. The day following the cloth is to be rinsed, as after aluming. A hundred and fifty pounds of the leaves of *uva ursi* are then to be boiled for two hours in water, and after being taken out, a small quantity of madder is to be added to the liquor, putting in the cloth at the same time, which is to remain about an hour and a half. It is then taken out and rinsed in water.[1] By this process, it is said, blue cloth receives a pretty good black, but white cloth becomes only of a deep brown. It is said, too, that the madder and tartar are useless ingredients.

Last operation.

After the different operations for dyeing the cloth have been finished, it is washed in a river, and fulled, till the water comes off clear and colourless. Soap suds are recommended by some in fulling fine cloths, but it is found difficult to free the cloth entirely from the soap. After the cloth has come from the fulling-mill, some propose to give it a dip in a bath of weld, by which it is said to be softened, and the colour better fixed; but, according to Lewis, this operation, which in other cases is of some advantage, is useless after the cloth has been treated with the soap suds.

III.—*Of the Processes for dyeing Silk Black.*

In communicating a black colour to silk, different operations are necessary, such as boiling, galling, repairing the bath, dyeing, and softening.

To give a deeper shade to silk, it is necessary to deprive it of the gummy substance to which its stiffness and elasticity are owing. This is done by boiling the silk four or five hours with one fifth its weight of white soap, and afterwards beetling and carefully washing it.

Galling.

In conducting the process of galling silk, three fourths of its weight of galls are to be boiled for three or four hours; but the proportion of galls must depend on their quality. After the boiling, the liquor is allowed to remain at rest for two hours; the silk is then put into the bath, and left there from twelve to thirty-six hours, when it is to be taken out, and washed in the river. But as silk is capable of combining with a great proportion of the astringent principle, or tan, from which it receives a considerable increase of weight, it is allowed to remain for a longer or shorter time, as the silk is required to have more or less additional weight. To communicate, therefore, to silk, what is called a *heavy* black, it is allowed to remain longer in the gall liquor: the process is repeated oftener, and the silk is also dipped in the dye a greater number of times.

Dyeing.

While silk is preparing for the process of dyeing, the bath is to be heated, and should be occasionally stirred, that the grounds which fall to the bottom may not acquire too much heat. It should always be kept under the boiling temperature. Gum and solution of iron are added in different proportions, according to the different processes.

[1] *Stockholm Trans.* 1753.

Simple Colours.

When the gum is dissolved, and the bath near the boiling temperature, it is left to settle for about an hour. The silk, which in general is previously divided into three parts, that each may be successively put into the bath, is immersed in it. Each part is then to be three times wrung, and after each wringing hung up to air. The silk being thus exposed to the action of the air, acquires a deeper shade. This operation being finished, the bath is again heated, with the addition of gum and sulphate of iron; and this is repeated two or three times, according as the black required is light or heavy. When the process of dyeing is finished, the silk is rinsed in a vessel with some cold water, by turning or shaking it over.

Softening.

Silk, after it has been taken out of the dye, is extremely harsh, to remove which it is subjected to the operation of softening. A solution of four or five pounds of soap for every hundred pounds of silk is poured through a cloth into a vessel of water. The solution being completed, the silk is immersed, and allowed to remain in it for about fifteen minutes; it is then to be wrung out and dried.

Dyeing raw silk.

When raw silk is to be dyed, that which has a natural yellow colour is preferred. The galling operation must be performed in the cold, if it be proposed to preserve the whole of the gum, and the elasticity which it gives to the silk; but if part only of the gum is wished to be preserved, the galling is to be performed in the warm bath.

The dyeing operation is also performed in the cold. All that is necessary is to add the sulphate of iron to the water in which the stuff is rinsed. By this simple process the black dye is communicated. It is then washed, once or twice beetled, and dried without wringing, that its elasticity may not be destroyed. Raw silk may be dyed by a more speedy process. After galling, it may be turned or shaken over in the cold bath; and thus, by alternately dipping and airing the stuff, the operation may be completed. It is then to be washed and dried, as in the former process.

A speedier process.

Improved process for velvet.

The method of dyeing velvet at Genoa, which has been simplified and improved in France, is thus described by Macquer. For every hundred pounds of silk, twenty pounds of Aleppo galls, reduced to powder, are boiled in a sufficient quantity of water for an hour. The bath is allowed to settle till the galls have fallen to the bottom; they are then taken out, and two pounds and a half of sulphuric acid, twelve pounds of iron filings, and twenty pounds of gum, are put into a copper vessel, or cullender, furnished with two handles. This vessel is immersed in the bath, and supported that it may not touch the bottom. The gum, which is allowed to dissolve for an hour, is to be occasionally stirred; and if it appear that the whole of the gum is dissolved, three or four pounds more are to be added. Excepting during the operation of dyeing, the cullender is to remain in the copper, which must be kept hot the whole time, but at a temperature below the boiling point. In galling the silk, one third of Aleppo galls is employed, and the stuff should remain six hours in the liquor the first time, and twelve hours the second. By frequent additions of sulphate of iron, and repeated immersions of the stuff, a fine black, according to Lewis, has been obtained. In the above process, the proportion of sulphate of iron is too small; and the gum, according to some, being carried off in the washing, may be considered as useless. Berthollet thinks, that although the quantity be excessive, it has some effect in keeping up the bath; and he adds, if it is to be diminished, it would be useful to add the sulphate of iron in separate portions during each interval.

Simple Colours.

Substitute for galls.

To diminish the quantity of galls, which are an expensive ingredient in dyeing silk black, other substances have been proposed as substitutes. With this view the following process is recommended.

The silk being boiled and washed, is immersed in a strong decoction of green walnut peels, and allowed to remain till the colouring matter of both is exhausted. It is then to be slightly wrung out, dried, and washed.[1] To give the silk a blue ground, logwood and verdigris are employed, in the proportion of one ounce of the latter for every pound of silk. The verdigris is dissolved in cold water, and the silk is allowed to remain two hours in this solution. It is then immersed in a strong decoction of logwood, slightly wrung out, dried, and afterwards washed at the river. The bath is prepared by macerating two pounds of galls and three of sumach in twenty-five gallons of water, over a slow fire, for twelve hours. The liquid being strained, three pounds of sulphate of iron and the same quantity of gum-arabic are to be dissolved in it. The silk is dipped in this solution at two different times; it is to remain in the bath two hours each time, and it must be aired and dried between each dip. After being twice beetled at the river, it is dipped a third time, and left in the bath four or five hours, after which it is to be dried, washed, and beetled, as before. The temperature of the bath should not exceed 120°. After the first dipping, it may be necessary to add half a pound of sulphate of iron, and an equal quantity of gum-arabic.

Silk which has been previously dyed blue with indigo, it is said, takes only a mealy black; but when it has been prepared with logwood and verdigris, it acquires a velvety lustre. A fine black may be obtained from green walnut peel; but the addition of logwood and verdigris renders a smaller quantity of sulphate of iron necessary, and this is of importance, because it is apt to weaken the silk. The only use of galls, according to some, is to increase the weight of the silk; for the purposes of dyeing, sumach is considered sufficient.[2]

IV.—*Of the Processes for dyeing Cotton and Linen Black.*

Must be previously dyed blue.

It is more difficult to communicate a fine black to linen or cotton than to silk or woollen stuffs. To succeed in producing a black colour of that degree of intensity which will resist soap, it is necessary to adopt particular processes. In dyeing animal matters black, as silk and wool, the best colours are obtained on those which have been previously dyed blue. This also is an essential preliminary process in dyeing linen and cotton black; for it is found that the process which succeeds best is first to give a deep blue grain to the cotton or linen.

Galling.

The first part of the process is the operation of galling. The stuffs, which have been previously dyed blue, wrung out, and dried, are kept twenty-four hours in the gall liquor, composed of four ounces of galls to every pound of thread. A bath is then prepared of a solution of iron in acetic acid. This solution is obtained by saturating the acid with oxide of iron. In France, vinegar, small beer, or small wine, is employed for this purpose. To promote the acid fermentation, rye meal, or some other substance, is added, and pieces of old iron are thrown into the liquid, which are allowed to remain for six weeks or two months, that the acid may be saturated with the iron. This solution, called *iron liquor* in this country, is prepared from fermented worts, to which old iron is added, as is described above. Five quarts of the iron liquor for every pound of stuffs are put into a vessel. In this the stuffs are wrought with the hand, pound by pound, for fifteen mi-

Dyeing.

[1] The decoction of walnut peels is prepared by boiling for fifteen minutes, after which it is taken from the fire. After it has subsided, the silk, which has been previously immersed in warm water, is dipped in it.

[2] Berthollet, ii. 20.

Simple Colours.

nutes; they are then wrung out and aired. This operation is to be again repeated, taking care to add a fresh quantity of the iron liquor, which should be carefully scummed, after which the stuffs are to be wrung out, aired, and washed at the river. In the next operation, a pound of alder bark for every pound of stuff is boiled in a sufficient quantity of water for an hour. One half of the bath which was employed in the galling, and about one half the quantity of sumach as of alder bark, are then added. The whole is boiled together for two hours, and strained through a sieve. When this liquid is cold, the stuffs are immersed, wrought pound by pound, and occasionally aired. They are afterwards put into the bath, and, after remaining for twenty-four hours, are wrung out and dried. The above is the process which, according to D'Apligny, is followed at Rouen for dyeing cotton and linen.

Another process.

The process followed at Manchester, which is described by Mr Wilson, is the following. For the operation of galling, galls or sumach are employed. The stuff is afterwards dyed in a bath consisting of a solution of iron in acetic acid. This bath is also frequently composed of alder bark and iron. After having passed through this bath, the stuff is dipped in a decoction of logwood, to which a small quantity of verdigris has been added. This process is to be repeated till a black of sufficient intensity is obtained, observing to wash and dry after each operation.

Preparation of solution of iron.

According to Guhliche, a solution of iron may be prepared by the following process. A pound of rice is to be boiled in twelve or fifteen quarts of water, till the whole is dissolved. A sufficient quantity of old iron made red hot, to reach half way to the surface of the liquor, is thrown into the solution. The vessel in which the solution is kept must be under cover, but exposed to the air and light, at least for a week. In another vessel, containing a quantity of warm vinegar equal to the solution of rice, an equal quantity of red-hot iron is to be put. This vessel must also be exposed in the same way to the air and light. After several days, the contents of both vessels are mixed together, and the mixture is to be exposed for a week to the open air, after which it is to be decanted and kept for use in a close vessel. To give a sufficient

Its application.

black to linen and cotton, it is only necessary, it is said, to steep them twenty-nine hours in this solution; and if it should appear that the liquor is exhausted of colouring matter, a fresh portion is to be employed. In this way a fine permanent black is obtained. According to the same author, this solution may be advantageously employed as a substitute for sulphate of iron, in dyeing silk and wool. But to give them a fine black, silk and woollen stuffs must be dipped in a decoction of logwood after they are taken from the bath.

Sect. V.—*Of Brown.*

The last of the simple colours is brown. This is also known under the name of *fawn* colour (*fauve*, Fr.). It is that brown colour which has a shade of yellow, and might perhaps be considered as a compound colour, although it is communicated to stuffs by one process.

I.—*Of the Substances employed in Dyeing Brown.*

Walnut peels.

The vegetable substances which are capable of inducing a fawn or brown colour on different stuffs are very numerous, but those chiefly employed for this purpose are walnut peels and sumach. The peels constitute the green covering of the nut; they are internally of a white colour, which is converted into brown or black by exposure to the air. The skin, when impregnated with the juice of walnut peels, becomes of a brown or almost black colour. When the inner part of the peel, taken fresh, is put into weak oxymuriatic acid, it assumes a brown colour. If the decoction of walnut peels be filtered and exposed to the air, its colour becomes of a deep brown; the pellicles on evaporation are almost black; the liquor detached from these yields a brown extract, completely soluble in water. The colouring particles are precipitated from a decoction of walnut peels by means of alcohol, and they are soluble in water. No apparent change is at first produced by a solution of potash; but it gradually becomes turbid, and the colour is deepened. A copious precipitate, of a fawn colour, approaching to an ash colour, is produced in a decoction of walnut peels, by means of a solution of tin, and the remaining liquor has a slightly yellow tinge.

Properties.

A decoction of walnut peels yields a small quantity of fawn-coloured precipitate by means of a solution of alum, and the liquor remains of the same colour. Sulphate of copper renders it slowly turbid, and throws down a small quantity of precipitate of a brownish-green colour, leaving the supernatant liquor of the same colour. Sulphate of iron deepens the colour; when diluted, the colour becomes brownish green, without the deposition of any sediment. Sulphate of zinc also deepens the colour, and produces no precipitate. The same properties are exhibited by a decoction of the walnut-tree wood, but the colouring matter is not obtained from it in such abundance as from the peels; and the bark may also be used with advantage in dyeing.

Advantages.

The affinity of the colouring matter of walnut peels for wool is very strong; and it readily imparts to it a durable colour, which even mordants do not seem capable of increasing, but they are generally understood to give it additional brightness. A lively and very rich colour is obtained with the assistance of alum. Walnut peels afford a great variety of pleasing shades; and as they require not the intervention of mordants, the softness of the wool is preserved, and the process of dyeing becomes both cheap and simple.

Preparation.

Walnut peels are not gathered till the nuts are completely ripe, when they are put into large casks, along with as much water as is sufficient to cover them. When used in dyeing at the Gobelins in Paris, Berthollet informs us, they are kept for upwards of a year, and very extensively used; but if not made use of till the end of two years, they yield a greater quantity of colouring matter, at which time their odour has become peculiarly disagreeable and fetid. The peels separated from the nuts before they arrive at maturity, may likewise be used in dyeing, but in this state they do not keep so long.

Sumach.

Sumach (*rhus coriaria*, Lin.) is a shrub produced naturally in Palestine, Syria, Portugal, and Spain, being carefully cultivated in the last two of these countries. Its shoots are annually cut down, dried, and reduced to powder in a mill, by which process they are prepared for the purposes of dyeing.

Properties.

The infusion of sumach, which is of a fawn colour with a greenish tinge, is changed into a brown by exposure to the air. A solution of potash has little action on the recent infusion of sumach; its colour is changed to yellow by the action of acids; the liquor becomes turbid by means of alum, a small quantity of precipitate being at the same time formed, and the supernatant liquor remaining yellow. A copious precipitate of a yellowish-green colour is thrown down by sulphate of copper, and the liquor remains clear. No change is speedily produced by muriate of soda (common salt), but it becomes rather turbid at the end of some hours, and its colour is rather clearer. Sulphate of copper produces a copious precipitate of a yellowish green, which after standing some hours changes to a brownish green; the supernatant liquor, which is slightly

Simple Colours.

yellow, remains clear. Sulphate of zinc renders the liquor turbid, darkens its colour, and produces a deep blue precipitate; but when the sulphate of zinc is pure, the precipitate, which is of a brownish fawn colour, is in very small quantity. Acetate of lead gives a copious precipitate of a yellowish colour; the supernatant liquor is of a clear yellow colour. No astringent has so strong a resemblance to galls as sumach; but the precipitate thrown down from an infusion of it by a solution of iron, is not so copious as that which is yielded by an equal quantity of galls, on which account sumach may be generally employed as a substitute for galls, only its quantity will require to be increased.

Bark of birch.

The bark of the birch tree (*betula alba*, Lin.) yields a decoction of a clear fawn colour, but it soon becomes turbid and brown. The addition of a solution of alum, in the open air, produces a copious yellow precipitate; a solution of tin gives also a copious precipitate of a clear yellow colour. With solutions of iron the decoction of the birch tree strikes a black colour, and it dissolves in considerable quantity the oxide of iron, but in smaller proportion than the decoction of walnut peels. On account of this property, it is employed in the preparation of black vats for dyeing thread.

Sandal wood.

Sanders or sandal wood (*Petrocarpus sachtalinus*) is also employed for the purpose of giving a fawn colour. There are three kinds of sandal wood, the white, the yellow, and the red. The last only, which is a compact heavy wood, brought from the Coromandel coast, is used in dyeing. By exposure to the air it becomes of a brown colour; when employed in dyeing, it is reduced to fine powder, and it yields a fawn colour with a brownish shade, inclining to red. But the colouring matter which it yields of itself is in small quantity, and it is said that it gives harshness to woollen stuffs. When it is mixed with other substances, as sumach, walnut peels, or galls, the quantity of colouring matter is increased; it gives a more durable colour, and produces considerable modifications in the colouring matter with which it is mixed. Sandal wood yields its colouring matter to brandy, or diluted alcohol, more readily than to water.

Soot.

Soot communicates to woollen stuffs a fawn or brown colour, of a lighter or deeper shade, in proportion to the quantity employed; but the colour is fading, and its affinity for wool is not great; and besides leaving a disagreeable smell, it renders the fibres harsh. In some manufactories it is employed for browning certain colours, and it produces shades which could not otherwise be easily obtained.

II.—*Of the Processes for dyeing Woollen, &c. a Fawn or Brown Colour.*

With walnut peels.

In dyeing with walnut peels, a quantity proportioned to the quantity of stuff, and the intensity of shade wanted, is boiled for fifteen minutes in a copper. All that is necessary in dyeing with this substance is, to moisten the cloth or yarn with warm water previous to its immersion in the copper, in which it is to be carefully stirred till it has acquired the proper shade. This is the process if the aluminous mordant is not employed. In dyeing cloth, it is usual to give the deepest shades first, and the lighter ones afterwards; but in dyeing woollen yarn, the light shades are given first, and the deeper ones afterwards. An additional quantity of peels is joined to each parcel.

Berthollet's experiments.

Berthollet made a number of experiments to ascertain the difference of colour obtained from the simple decoction of walnut peels, and the addition of metallic oxides as mordants. The oxide of tin, he found, yielded a clearer and brighter fawn colour than that of the simple decoction. The oxide of zinc produced a still clearer colour, inclining to ash or gray. The colour from oxide of lead had an orange cast, while that from oxide of iron was of a greenish brown.[1]

Compound Colours.

Dyeing with sumach.

A fawn colour, which has a shade of green, is obtained from sumach alone; but to cotton stuffs which have been impregnated with printers' mordant, or acetate of alumina, sumach communicates a good and durable yellow. Here, however, some precaution is necessary in the use of this substance for this purpose; for as the colouring matter is of so fixed a nature, the ground of the stuff cannot be bleached by exposure on the grass. This inconvenience is avoided by impregnating the whole of the stuff with different mordants, producing in this way a variety of colours, and leaving no part white.

With sandal wood.

Vogler employed the tincture of sanders wood for dyeing patterns of wool, silk, cotton, and linen, having previously impregnated them with a solution of tin, and afterwards washing and drying them. Sometimes he used the solution unmixed, and at other times added six or ten parts of water, and in whatever way he employed it he obtained a poppy colour. When the mordant employed was the solution of alum, the colour was a rich scarlet; with sulphate of copper it was a clear crimson, and with sulphate of iron a beautiful deep violet.[2]

CHAPTER V.

OF COMPOUND COLOURS.

Nature of compound colours.

A mixture of two colouring substances, it is well known, produces a very different shade from that of either of the uncombined colouring matters; hence compound colours are obtained, which are merely mixtures of simple colours. It would undoubtedly be a desirable thing to ascertain with accuracy the peculiar shade produced by the combination of two colouring matters; but these results can only be certainly known by experiment, because by the action of different substances in the bath they are subject to great variations in their effects, according to the affinities which are brought into action, and the new combinations which are formed. What is natural to colouring particles is not to be considered as a constituent part of compound colours, but only the difference of shade which they ought to assume with a particular mordant, or in a particular bath. The effects, therefore, of the chemical agents employed in these processes, and the result of different combinations, ought to be particularly attended to. It is in dyeing compound colours that skill and ingenuity are most conspicuous, and their application of greatest utility, to enable the dyer to vary his processes according to the shade desired, and at the same time to accomplish his operations by the shortest and cheapest means.

Great variety of shade.

As compound colours are obtained by the mixture of simple colours, very different shades will be obtained from different proportions of the simple colours; hence compound colours exhibit an indefinite variety of shade, and the processes by which they are produced are very numerous. It would extend this treatise to an unusual length were we to attempt to describe every variety of shade which is obtained from the mixture of simple colours. We shall therefore limit our observations to some of the principal

[1] *Elements of Dyeing*, ii. 296.

[2] *Crell. Ann.* 1790

Compound Colours.

compound colours, and an account of the processes by which they are obtained, leaving it to our readers, who have made themselves familiar with the principles already detailed, to vary these colours by employing different proportions and different combinations of simple colouring matters.

Compound colours have been usually divided into four classes, namely, green, purple, orange, and gray or drab colour. These are obtained from mixtures of the following simple colours:

1. Blue and yellow produce a green.
2. Red and blue produce a purple, &c.
3. Red and yellow produce orange.
4. Black and other colours produce gray, &c.

The following sections will be occupied in a short detail of the methods which are usually employed in producing these different compound colours.

Sect. I.—*Of the Mixture of Blue and Yellow, or Green.*

Various shades of green.

Green colours, from the great variety of shades which they exhibit, have been long known by different names, by which the intensity of shade is characterized, such as sea-green, apple-green, meadow or grass-green, pea-green, parrot-green, &c. Many plants afford a green colour, such as brome grass (*bromus secalinus*, Lin.) green berries of *rhamnus frangula*, wild chervil (*chærophyllum sylvestre*, Lin.), purple clover (*trifolium pratense*), common reed (*arundo phragmites*). These colours, however, do not possess sufficient permanency. According to D'Ambourney, indeed, a permanent green may be obtained from the fermented juice of the berries of the berry-bearing alder (*rhamnus frangula*). Having previously prepared the cloth with tartar, solution of nitrate of bismuth, and common salt, he added to the fermented juice of the berries, after it was warmed, a small proportion of acetate of lead; and in this bath he communicated to the cloth an intermediate shade between parrot and grass green. But it is usually from the mixture of blue and yellow that green is obtained; and it may be observed, that it requires much skill and experience, especially in giving light shades, to produce a colour which is uniform and entirely without spots.

I.—*Of the Processes for dyeing Woollen Stuffs Green.*

Common process.

To dye woollen green, either the yellow or the blue dye may be given to it first. But when the stuff is first dyed yellow, and in this state is introduced into the blue vat, part of the yellow colouring matter being dissolved in the vat, communicates to it a green colour, which renders it unfit for dyeing any other colour than green. To avoid this inconvenience, therefore, the blue colour is first given, and afterwards the yellow. It would be quite unnecessary to resume the account of any part of the processes for dyeing blue, which have been already detailed. It is proper, however, to add, that the intensity of the blue shade must be proportioned to the green, or to the depth of the green colour which is wished to be obtained. Thus, for instance, to produce a parrot green, a ground of sky blue is given, and for the green like that of a drake's neck, a deep blue is required. When the blue dye has been communicated, the yellow is afterwards given, according to some of the processes which have been already described for dyeing yellow. The proper ground being communicated to the cloths, they are washed in the fulling mill, and boiled as for the common process of welding; but when the shade is light, the proportion of salts should be less. Cloths which are to receive light shades are first boiled, and when these are taken out, tartar and alum are added in fresh portions till the cloths which are intended for the darkest shades are boiled. The process of welding is conducted in the same way as for dyeing yellow, with this difference, that a larger proportion of weld is employed, excepting for lighter shades, when the proportion must be smaller. In dyeing green, it is usual to have a succession of shades at the same time; the process is begun with the deepest and ends with the lightest. Between each dip there should be an interval of one half or three quarters of an hour, and at each interval water is added to the bath. It is the practice of some dyers to give each parcel two dips, beginning the first time with the deep shades, and the second with the lighter ones; but when this practice is followed, the time of immersion should be shortened. In dyeing very light shades, the bath should never be permitted to reach the boiling temperature. For deep greens, a browning is given with logwood and a small proportion of sulphate of iron.

Saxon green.

For some kinds of green, sulphate of indigo is employed; and in this case either the blue and yellow are dyed separately, or the whole of the ingredients are mixed together in the bath, and the whole process is finished at a single operation. The colour thus obtained has been distinguished by the name of *Saxon green*. The following is the process recommended by Dr Bancroft.

"The most beautiful Saxon green," says he, "may be produced very cheaply and expeditiously, by combining the lively yellow which results from quercitron bark, murio-sulphate of tin, and alum, with the blue afforded by indigo when dissolved in sulphuric acid, as for dyeing the Saxon blue.

"To produce this combination most advantageously, the dyer, for a full-bodied green, should put into the dyeing vessel after the rate of six or eight pounds of powdered bark in a bag for every 100 pounds weight of cloth, with only a small proportion of water as soon as it begins to grow warm; and when it begins to boil, he should add about six pounds of murio-sulphate of tin (with the usual precautions), and a few minutes after, about four pounds of alum. These having boiled together five or six minutes, cold water should be added, and the fire diminished so as to bring the heat of the liquor nearly down to what the hand is able to bear; and immediately after this, as much sulphate of indigo is to be added as will suffice to produce the shade of green intended to be dyed, taking care to mix it thoroughly with the first solution by stirring, &c.; and this being done, the cloth, previously scoured and moistened, should be expeditiously put into the liquor, and turned very briskly through it for a quarter of an hour, in order that the colour may apply itself equally to every part, which it will certainly do in this way with proper care. By these means, very full, even, and beautiful greens may generally be dyed in half an hour; and during this space it is best to keep the liquor at rather less than a boiling heat. Murio-sulphate of tin is infinitely preferable for this use to the dyer's spirit, because the latter consists chiefly of nitric acid, which, by its highly injurious action upon indigo, would render that part of the green colour very fugitive, as I have found by repeated trials. But no such effect can result from the murio-sulphate of tin, since the muriatic acid has no action upon indigo; and the sulphuric is that very acid which alone is proper to dissolve it for this use.

"Respecting the beauty of the colour thus produced, those who are acquainted with the unequalled lustre and brightness of the quercitron yellows, dyed with the tin basis, must necessarily conclude that the greens composed therewith will prove infinitely superior to any which can result from the dull muddy yellow of old fustic; and in point of expense it is certain that the bark, murio-sulphate of tin, and alum, necessary to dye a given quantity of cloth in this way will cost less than the much greater quantity

Compound Colours.

(six or eight times more) of fustic, with the alum necessary for dyeing it in the common way, the sulphate of indigo being the same in both cases. But in dyeing with the bark, the vessel is only to be filled and heated once, and the cloth, without any previous preparation, may be completely dyed in half an hour: whilst in the common way of producing Saxon greens, the copper is to be twice filled; and to this must be joined the fuel and labour of an hour and a half's boiling and turning the cloth in the course of preparation, besides nearly as much boiling in another vessel to extract the fustic; and after all, the dyeing process remains to be performed, which will be equal in time and trouble to the whole of the process for producing a Saxon green with the bark; so that this colour obtained from bark will not only prove superior in beauty, but in cheapness, to that dyed as usual with old fustic."[1]

II.—*Of the Processes for dyeing Silk Green.*

Preparation.

In giving silk a green colour, greater precaution is necessary, to preserve uniformity of colour, and to prevent spots and stripes. Silk which is intended to receive a green colour is scoured in the same way as for other colours; but for light shades the scouring must be as complete as for blue. Silk which is to be dyed green is first dyed yellow, and being well alumed, it is slightly washed at the river, and divided into small parcels, that it may receive the colouring matter uniformly, and then carefully turned in the weld bath. When the ground is supposed to have acquired a sufficient degree of intensity, a pattern is put into the blue vat to ascertain the proper shade. When this is the case, the silk is taken out of the bath, washed, and immersed in the blue vat. To produce a deeper colour, and at the same time to give variety of shade, a decoction of logwood, fustic, or anotta is added to the yellow bath, after the weld has been taken out. For very light shades, such as apple and sea green, it is scarcely necessary to add, that a weaker ground is to be given. For all light shades, except sea-green, the process is found to succeed better when the yellow is communicated by baths which have been already used; but these baths should not contain any logwood or fustic.

Saxon green.

Saxon green is produced by means of sulphate of indigo. This is a brighter but less durable colour than the former. This process is conducted by boiling as for welding, after which the cloth is washed. Fustic in chips is enclosed in a bag, put into the same bath, and boiled for an hour and a half, when it is taken out, and the bath allowed to cool till the hand can bear it. A pound and a quarter of sulphate of indigo for each piece of cloth of eighteen yards is added. The cloth is at first to be turned quickly, and afterwards more slowly, and it should be taken out before the bath boils. Some dyers put in only two thirds of the solution at first, and after two or three turns take out the cloth and add the other one third. By this means the colour is more uniform.

By one operation.

To produce Saxon green at one operation, the following process is recommended by Dr Bancroft. A bath is prepared of four pounds of quercitron bark, three pounds of alum, and two pounds of murio-sulphate of tin, with a sufficient quantity of water. The bath is boiled ten or fifteen minutes, and when the liquor is so far reduced in temperature as the hand can bear it, it is fit for dyeing. By adding different proportions of sulphate of indigo, various and beautiful shades of green may be obtained, and the colour thus produced is both cheap and uniform. Care should be taken to keep the bath constantly stirred, to prevent the colouring matter from subsiding. Those shades which are intended to incline most to the yellow should be dyed first; and by adding sulphate of indigo, the green having a shade of blue may be obtained. This process, Dr Bancroft observes, is the most commodious and certain for dyeing most beautiful Saxon greens upon silk.[2]

English green.

To produce English green, which is more beautiful than common green, and is said to be more durable than the Saxon green, Guhliche gives the following process. He first dyes the silk of a light blue in the cold vat already described, then soaks it in warm water, washes it in a stream, and dips it in a weak solution of alum. He then prepares a bath of sulphate of indigo, one ounce of solution of tin, with the tincture of French berries made with aceto-citric acid. The silk is kept in this bath till it has obtained the desired colour. It is then washed and dried in a shady place. Lighter shades may be dyed afterwards.[3]

III.—*Of the Processes for dyeing Cotton and Linen Green.*

Blue first given.

Cotton and linen, after being scoured in the usual way, are first dyed blue, and after being cleansed, they are dipped in the weld bath, to produce a green colour. The strength of the blue and yellow is proportioned to the shade of green which is wanted. But as it is difficult to give to cotton velvet a uniform colour in the blue vat, it is first dyed yellow with turmeric, and the process is completed by giving it a green with sulphate of indigo. The same result, however, will be obtained by commencing the process either with the yellow or the blue.

Process for cotton velvet.

The process which D'Apligny describes for dyeing cotton velvet, or cotton thread, a sea or apple green, in one bath, is the following. A quantity of verdigris is dissolved in vinegar, and the mixture is kept excluded from the air in the heat of a stove for fifteen days. A quantity of potash equal in weight to the verdigris employed is dissolved in water, and, four hours before dyeing, it is added to the solution of verdigris. The mixture is to be kept hot. One ounce of alum in five quarts of water for each pound of stuff being prepared, the cotton thread or velvet is soaked in this solution. It is then taken out, and the verdigris being added to the solution of alum, it is again introduced to be dyed.

Olive green

The different shades of olive green, and drake's neck green, are given to thread after it has received a blue ground, by galling it, and dipping it in a weaker or stronger bath of iron liquor, then in the weld bath, to which verdigris has been added, and afterwards in the bath with sulphate of copper. The colour is lastly to be brightened with soap.

Green from Prussian blue.

Cotton dyed with Prussian blue may be dyed green by previously aluming while it is still wet with the blue, and then dipping in a weld bath, the strength of which is proportioned to the shade required. The colour from weld is more lively than that obtained from fustic. But fustic, which gives a deeper shade than weld, and diminishes the brightness of the blue, is to be preferred when a green with an olive shade is wanted.

General remarks.

The shade of green given to any stuff, it is obvious, must vary according to the intensity of the blue shade, the strength of the yellow bath, and the nature of the yellow colouring matter employed. Yellow colours are rendered more intense by means of alkalies, sulphate of lime, and ammoniacal salts; but become fainter by means of acids, alum, and solutions of tin. In dyeing Saxon green the result will be different according to the process which is followed. The effects will be different by adding a yellow to a Saxon blue, from the process in which the sulphate of indigo is mixed with the yellow ingre-

[1] *Phil. of Perm. Col.* 336. [2] *Ibid.* 346. [3] Berthollet, ii. 319.

Compound Colours.

dients; because in the latter case the sulphuric acid has a considerable action on the colouring matter, and thus diminishes the intensity of the yellow. As the particles of indigo have a stronger affinity for the stuff than the yellow colouring matter, in dyeing a succession of shades in a bath in which both are mixed, the bath being first exhausted of the indigo, the last shades incline more to the yellow, on account of the predominance of the yellow colouring matter.

Sect. II.—*Of the Mixture of Red and Blue, or Purple, &c.*

By the mixture of red and blue, violet, purple, dove-colour, lilac, and a great variety of other shades, according to the proportion of the substances employed, or the predominance of the blue or the red, are produced. In stuffs which are to be dyed violet, a deeper blue must be given; for purple colours, the ground requires to be of a lighter blue; but in lilac and other light colours, it is necessary that both the blue and the red have a light shade.

I.—*Of dyeing Wool Violet, Purple, &c.*

In the attempts which have been made to communicate a violet or purple colour to a scarlet ground, according to the observations of Hellot, the colour is very unequal. It becomes therefore necessary to give the blue colour first; and for violets or purples, the shade of blue ought not to be deeper than that of sky blue. The stuff being dyed blue, is boiled with alum, and two fifths of tartar, and is afterwards dipped in a bath composed of nearly two thirds the quantity of cochineal required for scarlet, with the addition of tartar. The same process, indeed, as for dyeing scarlet, is followed. It is a common practice to dye these colours after the reddening for scarlet, making such additions of cochineal and tartar as the intensity of the shade may require.

Lilac, &c. For lighter shades, as lilacs, dove-colours, &c. the stuff may be dipped in the bath which has served for violet and purple, and is now somewhat exhausted, taking care to add a quantity of alum and tartar. For reddish shades, such as a peach-blossom, a small proportion of solution of tin is added. It may be observed in general, that although the proportion of cochineal is less in dyeing lighter shades, the quantity of tartar must not be diminished.

Cheaper and shorter process. To obtain the same colours, a shorter and less expensive process is recommended by Poerner. In this process he employs sulphate of indigo. He boils the stuff in a solution of alum, in the proportion of three ounces of the latter to one pound of the former, for an hour and a half, and afterwards allows it to remain in the liquid for a night after it has cooled. The dyeing bath is prepared with an ounce and a half of cochineal, and two ounces of tartar, which are boiled for three quarters of an hour: two ounces and a half of sulphate of indigo are then added, the whole is stirred, and boiled gently for fifteen minutes. The dyeing operation is conducted in the usual way, and a beautiful violet is thus obtained. To have all the variety of shades which are produced by the mixture of red and blue, the proportion of the sulphate of indigo is increased or diminished. It is sometimes increased to five ounces, and diminished to five drachms, for each pound of stuff. The quantity of cochineal is also varied, but when it is less than an ounce the colour is dull. Different proportions of tartar are also employed. To produce variety of shades, the stuff is also prepared with different proportions of solution of tin.

Purple from logwood. To communicate a purple colour to wool, as well as some other shades, logwood, with the addition of galls, has been employed. The stuff is previously dyed blue, and, to give a brown shade, sulphate of iron is used; but the colours thus obtained are not permanent. By the following process, described by Decroizille, a durable dye is produced by means of this wood. He dissolved tin in sulphuric acid, to which were added common salt, red acidulous tartrite of potash, and sulphate of copper; or it may be more conveniently done by making a solution of tin in a mixture of sulphuric acid, common salt, and water, to which are to be added the tartrite and sulphate in the state of powder. Of this mordant not less than 1500 quarts were made in twenty-four hours, in a leaden vessel to which a moderate heat was applied. A very lucrative trade was carried on for three years by Decroizille, who sold it at the rate of 1s. 3d. sterling per pound.

Process. If wool in the fleece is to be dyed, it will require a third of its weight of this mordant, while a fifth is a proportion sufficient for stuffs. A bath is prepared of such a degree of temperature as the hand can bear, with which the mordant is properly mixed, and the wool or stuff dipped in it and stirred; the same degree of temperature being kept up for two hours, and increased a little towards the end; after which it is taken out, aired, and well washed. A fresh bath of pure water is prepared at the same temperature, to which is added a sufficient quantity of the decoction of logwood; the stuff is then immersed, stirred, and the heat increased to the boiling temperature, which is to be continued for fifteen minutes, after which, the stuff being taken out, aired, and carefully rinsed, the process of dyeing is completed. If for every three pounds of wool one pound of decoction of logwood has been used, and a proportionate quantity for stuffs which require less, a fine violet colour is produced, to which a sufficient quantity of Brazil wood imparts the shade known in France by the name of *prune de Monsieur.*

Different shades from other substances. Logwood and Brazil, fustic and yellow wood, are colouring substances which may be fixed with advantage upon wool by means of this mordant. The colour communicated by the two first of these is liable to be changed in the fulling by the action of the soap or urine employed for that purpose; but this change, which is always produced by alkaline substances, is remedied by a slightly acid bath a little hot, called *brightening*, for which the sulphuric acid has the preference. The colour becomes as deep, and frequently much brighter than before the change. Wools which have been dyed by means of this mordant are said to admit of being spun into a finer and more beautiful thread than by the use of alum. If the use of sulphate of copper is omitted, more beautiful colours are produced by fustic and yellow wood, as well as by weld. An orange-red colour is communicated by madder, but not so deep as with a similar quantity of alum. When sulphate of copper is omitted, the wool is said to become much harsher, and the mordant thus prepared yields but indifferent colours with logwood, and in particular with Brazil wood. The use and carriage of this mordant are inconvenient, on account of the heavy sediment by which the vessel is half filled under a corrosive liquor, capable only of being kept in stone ware. These inconveniences may be remedied by the omission of the water in the receipt, which leaves only a paste more conveniently used, and the carriage of it two fifths cheaper.

Nature of the process. The above process is thus explained by Berthollet. The decomposition of the muriate of soda is effected by the action of the sulphuric acid; and the muriatic acid being thus disengaged, dissolves the tin, part of which is precipitated by means of the tartaric acid, producing the sediment already mentioned. The oxide of copper produces the blue with the colouring particles of the logwood; the violet is formed by the oxide of tin with the same wood,

Compound Colours.

and the red with the colouring matter of the Brazil wood. The same ingenious chemist farther observes, that as an excess of acid is retained in the liquor, it might probably be of advantage to employ acetate as a substitute for sulphate of copper, in which case the action of the free acid would be moderated. He thinks it would still be more advisable to make use of verdigris; because the uncombined part of the oxide of copper would in that case unite with the excess of acid, on which account a smaller quantity of acid would remain in the liquor; and probably the quantity of tartar might be diminished, as a smaller quantity of tin would thus be precipitated.[1]

II.—*Of dyeing Silk Violet or Purple.*

Two kinds of violet.

Silk is capable of receiving two kinds of violet colours, denominated the fine and the false, the latter of which is produced by means of archil or Brazil wood. When the fine violet colour is required, the silk must first be passed through cochineal, and dipped afterwards in the vat. The preparation and dyeing of the silk with cochineal are the same as for crimson, with the omission of tartar and solution of tin, by means of which the colour is heightened. The quantity of cochineal made use of is always proportioned to the required shade, whether it is more or less intense; but the usual proportion for a fine violet colour is two ounces of cochineal for each pound of silk. When the silk is dyed it is washed at the river, twice beetled, dipped in a vat more or less strong in proportion to the depth of the violet shade, and then washed and dried with precautions similar to those which all colours require that are dyed in the vat. If the violet is to have greater strength and beauty, it is usual to pass it through the archil bath; a practice which, though frequently abused, is not to be dispensed with for light shades, which would otherwise be too dull.

Purple.

When silk has been dyed with cochineal according to the above directions, only a very light shade is requisite for purple; the shades which are deepest are dipped in a weak vat, while dipping them in cold water is sufficient for such as are lighter, the water having been incorporated with a small quantity of the liquor of the vat, because in the vat itself, however weak it might be, they would acquire too deep a tinge of blue. In this manner are the light shades of this colour, such as gilly-flower, peach-blossom, &c. produced by diminishing the quantity of cochineal.

False violets.

There are various ways of imparting to silk what are denominated the false violets; but those which are most frequently used, and possessed of greatest beauty, are prepared with archil, the bath of which is, in point of strength, to be suited to the colour required. Having been beetled at the river after scouring, the silk is turned in the bath on the skein sticks; and when the colour is deemed sufficiently deep, a pattern is tried in the vat, to ascertain whether it takes the violet colour intended to be produced. If the shade is found to have acquired the proper depth, the silk is beetled at the river and dipped in the vat, in the same way as for the fine violet colours; and less either of the blue or of the archil colour is given, according as it is meant that the red or blue shade of the violet colour should predominate.

Process of Guhliche.

The process recommended by Guhliche for communicating a violet colour to silk is the following. A pound of silk is to be soaked in a bath of two ounces of alum and a like quantity of solution of tin, after having carefully poured off the sediment formed in the mixture. The dye-bath is prepared with two ounces of cochineal reduced to powder, with a drachm of tartar, and the remaining part of the bath, which has answered the purpose of a mordant, with the addition of a sufficient quantity of water. When slightly boiled, such a quantity of solution of indigo is added as may communicate to the bath a proper shade of violet; after which the silk is immersed, and boiled till it has acquired the intended shade. It is then wrung, washed in a stream, and, like every other delicate colour, must be dried in the shade. The light shades exhaust the bath. But it ought to be observed that this colour, which is said to be a beautiful violet, possesses but little durability, and is apt to assume a reddish tinge, owing to the colour of the indigo fading first.

Another.

A violet colour may be imparted to silks by immersing them in water impregnated with verdigris, as a substitute for aluming, and next giving them a bath of logwood, in which they assume a blue colour, which is converted to a violet, either by the addition of alum to the bath, or by dipping them in a weaker or stronger solution of that substance, which communicates a red colour to the particles of logwood. This violet possesses but a small degree of beauty, and little durability; but if alumed silk be immersed in a bath of Brazil wood, and next in a bath of archil, after washing it at the river, a colour is obtained possessing a much higher degree of beauty and intensity. The process described above for dyeing wool succeeds equally well, according to M. Decroizille, in communicating to silk a violet colour.

III.—*Of dyeing Cotton and Linen Violet.*

Common process

The most ordinary mode by which a violet colour is communicated to cotton and linen stuffs, is first to give them a blue ground in the vat, proportioned to the required shade, and to dry them. They are afterwards galled, in the proportion of three ounces of galls to a pound of stuff, and being left in this bath for twelve or fifteen hours, are wrung out and dried again. They are next passed through a decoction of logwood, and when thoroughly soaked and taken out, the bath receives an addition of two drachms of alum and one of dissolved verdigris for each pound of cotton or thread. The skeins are then dipped again on the skein sticks, and turned for about fifteen minutes, when they are taken out and aired. They are next immersed in the bath for fifteen minutes, taken out, and wrung. To complete the process, the vat employed is emptied; half of the decoction of logwood not formerly made use of is now poured in, with the addition of two drachms of alum, and the thread is again dipped in it till it has acquired the shade proposed, which must always regulate the strength or weakness of the decoction of logwood. This colour resists in a considerable degree the action of the air, but in point of permanency is much inferior to that which is obtained from the use of madder.

Sect. III.—*Of the Mixtures of Yellow and Red, or Orange.*

Orange is the usual result of a composition of yellow and red colours; but an almost endless variety of shades may be produced, according as we vary the proportion of the ingredients, and the particular nature of the yellow made use of. It is sometimes the practice of dyers to combine blue with yellow and red, the result of which is the colour denominated *olive*. Many varieties may be obtained from the use of weld, saw-wort, dyers-weed, and other yellows, and by employing tartar, alum, sulphate of zinc, or sulphate of copper, in the bath, or in the preparation of the cloth.

[1] Berthollet, ii. 340.

I.—*Of dyeing Wool Orange.*

Orange by the scarlet process.

By a process exactly the same as that which is followed in communicating to stuffs a scarlet colour, an orange may be given to wool; but the quantity of red must be diminished, and that of the yellow increased. If wool is dyed a red colour by means of madder, and afterwards yellow with weld, the resulting compound is a cinnamon colour, and the most proper mordant in this case is a mixture of alum and tartar. The shades may be varied at pleasure by substituting other yellow dyestuffs instead of weld, and by varying the proportions as circumstances may require. Wool may receive a reddish yellow colour by passing it through a madder bath, after it has undergone the usual process for yellow, which has already been described. The strength of the madder bath is always to be proportioned to the shade required. Brazil wood is sometimes employed with yellow substances, or mixed with cochineal and madder. Snuff, chestnut, musk, and other shades are produced by substituting walnut-tree root, walnut peels, or sumach, for weld.

II.—*Of Dyeing Silk Orange, &c.*

Marone, &c.

Logwood, Brazil wood, and fustic, communicate to silk a marone and cinnamon colour, together with all the intermediate shades. The silk is scoured in the usual manner, alumed, and a bath is prepared by mixing together decoctions of the three different woods mentioned above, made separately, varying the quantity of each according to the shade intended to be given; but the proportion of fustic should be greatest. The silk is turned in the bath on the skein sticks, and when it is taken out, if the colour be uniform, it is wrung and again dipped in a second bath of these three ingredients, according to the effect produced by the first, in order to obtain the shade required.

Olive.

The blue vat is not made use of when an olive colour is to be communicated to silk. After being alumed, it is dipped in a bath of weld, which is made very strong. To this is afterwards added the juice of logwood, with a small quantity of solution of alkali when the silk is dipped. This converts it into green, and gives the olive colour. It is dipped again in this bath till it has acquired the shade wanted.

To communicate to it the colour known by the name of *rotten olive*, fustic and logwood are added to the bath after welding, without any alkali. If the colour wanted is to incline more to a red, the addition of logwood alone is sufficient. A sort of reddish olive may likewise be obtained by dyeing the silk in a fustic bath, to which a greater or less quantity has been added of sulphate of iron and logwood.

III.—*Of dyeing Cotton and Linen Orange, &c.*

Cinnamon colour.

A cinnamon colour is communicated to thread and cotton by commencing the process for dyeing them with verdigris and weld; they are afterwards to be dipped in a solution of sulphate of iron, denominated by the French *bain d'assurage*, and then wrung out and dried. As soon as they are dried, they are galled in the proportion of three ounces to the pound of stuff; then dried again, alumed as for red colours, and maddered. After being washed and dried, they are put into hot soap suds, and turned till they have acquired a sufficient degree of brightness. It is the practice of some dyers to add to the aluming a decoction of fustic.

Olive

By boiling four parts of weld and one of potash in a sufficient quantity of water, M. d'Apligny informs us, a fine olive colour is communicated to cotton and thread. Brazil wood which has been steeped for a night is boiled separately with a small quantity of verdigris, and these solutions are mixed together in various proportions, according to the particular shade required. The thread or cotton is dipped in the compound solution in the usual way.

Compound Colours.

Sect. IV.—*Of the mixture of Black with other Colours.*

Brown.

The compound colours which are obtained from the mixture of black and other colours, are brown, gray, drab, &c. according to the nature and proportions of the simple colours employed.

I.—*Of dyeing Woollen Stuffs Brown, Gray, &c.*

To give a browning to cloth, as soon as it has been dyed, it is dipped in a solution of sulphate of iron, with the addition of an astringent, which makes a *black bath.* It is more common to mix a small quantity of solution of iron with a bath of water, adding more till the dyed stuff dipped in it has received the intended shade. Sulphate of iron is sometimes added to the dye bath; but by dipping the dyed stuff in a solution of this salt, the end is more easily attained. It is the usual practice of M. Poerner to soak the stuff in a solution of sulphate of iron, to which other ingredients are sometimes added; and after having taken it out of the mordant, it is dipped in the dye bath.

Coffee colour.

In order to obtain coffee and damascene colours, with other shades of browns of the common dye, the first method is adopted; a colour more or less deep is communicated to them, according to the shade intended to be obtained by the browning; and a bath is made of galls, sumach, and alder bark, with the addition of sulphate of iron. Those stuffs are first dipped to which the lightest shades are to be communicated, and when these are finished, the browner ones are dipped, a quantity of sulphate of iron being added for each operation, proportioned to the effect intended to be produced.

Gray.

Bluish grays are communicated to stuffs, according to Poerner, by the solution of indigo in sulphuric acid, combined with a mixture of decoction of galls and sulphate of iron, varying the shades according to the different quantities of these ingredients made use of. If to a bath composed of cochineal, fustic, and galls, sulphate of iron be added, other shades are obtained.

For marone, and such other colours as bear a strong resemblance to it, sanders and galls are employed, and sometimes a browning with the addition of logwood. If dyed in the remains of a cochineal bath, these colours may be made to incline to a crimson or purple; and the same effect is produced by adding a small quantity of madder or cochineal to the bath. A little tartar gives a greater degree of brightness to the colour. With a mixture of galls, fustic, and logwood, and a greater or smaller quantity of madder, with the addition of a little alum, those colours may be communicated to stuffs which are known by the name of *hazel.* Hazel

Puce colour.

M. Guhliche produces what is called a *puce* colour, by boiling for fifteen minutes a pound of woollen stuff with two ounces of alum, a certain proportion of vinegar and solution of iron, after which he leaves it in the mordant for twelve hours. He then makes a bath with the decoction of two ounces of white galls carefully poured off from the sediment, and mixed with four ounces of madder, in which, when it grows hot, the stuff is immersed, after being taken out of the mordant, allowing it to remain there, while the temperature is gradually increased, till the colour intended has been imparted to it; after which it is boiled for two minutes, washed, and dried in the sun. The colour thus obtained possesses a great degree of durability. It is of a deeper brown by the omission of the alum and vinegar in the mordant; and after these colours the lighter shades are dyed. Sumach may be employed as a substitute for

Compound Colours. half of the madder. Different brown colours, possessing considerable permanency, may likewise be produced by the use of Brazil and logwood, if more or less of a solution of iron be mixed with a decoction of these substances. The wool being previously alumed and galled, is dyed in it.

II.—*Of dyeing Silk with Mixtures of Black, &c.*

Purple violet. M. Guhliche imparts to silk a purple violet without a blue ground, with a mixture of one part of galls dissolved in white wine, with three parts of water, in which a pound of silk is macerated for twelve hours, soaked in a mordant made up of two ounces of alum, one ounce of solution of tin, and half an ounce of muriatic acid. After wringing the stuff, it is dyed in a bath composed of two ounces of cochineal and a small quantity of solution of iron, till the intended shade has been communicated; and for shades which are lighter, the residua of these baths are sufficient, either separately or mixed together. Madder may be used in the same way, macerating a pound of silk in a solution of alum mixed with an ounce of muriatic acid and a quantity of solution of iron. When the stuff is wrung out, it is dyed in a bath made of eight ounces of madder. When deeper colours are wanted, some of the solution of galls in white wine is mixed with the madder and cochineal baths.

Silk may be dyed in a bath made of equal parts of Brazil and logwood juice, adding a certain quantity of solution of iron after the stuff has been soaked in a solution of two ounces of alum and an ounce of muriatic acid. If solution of galls be added, the colour becomes deeper.

Brick colour. Colours resembling that of brick may be produced by immersing silk in an anotta bath, after preparing it with a solution of galls mixed with a certain quantity of solution of iron. By the mixture of Brazil, logwood, archil, and galls, and by a browning with sulphate of iron, a number of different shades are produced; but the whole of them have more or less a tendency to fade, although their brightness is very pleasing to the eye.

III.—*Of dyeing Cotton and Linen with Mixtures of Black, &c.*

With black cask. A permanent violet colour may be given to thread and cotton, when scoured in the ordinary way, by preparing a mordant with two quarts of the bath of what is called the *black cask*, and four quarts of water, for each pound of stuff, which is made to boil, and the scum is removed which forms on the surface, till it wholly disappears. The liquor is poured into a vat, and, when warm, four ounces of sulphate of copper and one ounce of nitre are dissolved in it. The skeins are left to soak in it for ten or twelve hours, wrung out, and dried. If it is required to produce a deep violet colour, two ounces of verdigris must be added to the bath; and if the nitre be omitted, the colour becomes still deeper by galling the thread more or less prior to its being put into the mordant. If the nitre be increased, and the sulphate of copper be diminished, the violet colour becomes more inclined to lilac. A number of various shades may be produced by different modifications of the mordants employed.

Marone colour. Cotton is galled, dipped, and wrought in the common way, when different shades of marone colour are wanted. To the bath employed must be added more or less of the liquor of the black cask. The cotton is then washed in a bath mixed with verdigris, next welded, and dyed to a fustic bath, to which a solution of soda and alum is sometimes added. When the cotton prepared in this manner has been thoroughly washed, it is next well maddered, dipped in a weak solution of sulphate of copper, and last of all in soap suds.

Hazel. For some hazel and snuff colours, a browning is communicated to stuffs by means of soot, after the welding and madder bath, to which galls and fustic have been added; sometimes soot is mixed with this bath, and a browning is likewise imparted by means of a solution of sulphate of iron; and for browning colours, walnut peels are sometimes employed as a substitute for solutions of iron. For such wools as are designed for the manufacture of tapestry they are very advantageous, because the colour is not changed into yellow by exposure to the air, as is the case in browning, which is imparted by means of iron, but remains a considerable time without any sensible change. The hue is indeed rather dull, but its goodness and very moderate price are sufficient to recommend a more extensive use of it for grave colours, which in common stuffs are sometimes fashionable.

CHAPTER VI.

OF CALICO-PRINTING.

Calico-Printing. Calico-printing is the art of communicating different colours to particular parts of the surface of cotton or linen cloth, while the rest of the cloth retains its white colour; or the whole of the cloth may be dyed one colour, as *red* or *blue*, except particular parts, to which some other colours, as yellow, orange, green, &c. are given. The process is not confined to linen and cotton cloth; it may be applied also to silk and woollen cloth; but as the nature of the processes is in all cases the same, it will answer our purpose sufficiently if we give a sketch of the methods followed by the *calico-printers*.

There is a curious passage in Pliny's Natural History, from which it is evident that calico-printing in his time (the first century) was understood and practised in Egypt. The following is a translation of this passage.

Practised by the ancients. "There exists in Egypt a wonderful method of dyeing. The white cloth is stained in various places, not with dye-stuffs, but with substances which have the property of absorbing *(fixing)* colours. These applications are not visible upon the cloth; but when the pieces are dipt into a hot caldron containing the dye, they are drawn out an instant after dyed. The remarkable circumstance is, that though there be only one dye in the vat, yet different colours appear on the cloth; nor can the colours be afterwards removed."[1] It is evident enough that the substances employed to stain the cloth, as Pliny expresses it, were different mordants, which served to fix the dye upon the cloth. Thus if we suppose certain parts of a piece of cotton cloth to be impregnated with alumina, and the cloth afterwards dyed with madder, after the clearing, those parts only impregnated with the mordant would retain their red colour, while the remaining parts will continue white.

The general opinion is, that this ingenious art originated in India, and from that country made its way into Egypt. Whether this notion be well or ill founded, it is certain that calico-printing was known and executed by the Indians at a very early period. Their colours were beautiful and fast, and the varieties of pattern and the number of colours which they understood to fix on different parts of the cloth gave to their printed calicoes a beauty and a value of no ordinary kind; but their processes are so tedious and so clumsy that they could be put in practice only where labour was exceedingly cheap.

[1] Plinii *Hist. Nat.* xxxv. 11.

Calico-Printing.

Introduced into Europe.

It is not more than a century and a half since calico-printing was transferred from India to Europe, and little more than a century since it became common in Great Britain. The nations with whom it has made the greatest progress are Switzerland, France (especially in Alsace), some parts of Germany, and Great Britain. In Europe the art has been in a great measure created anew. By the application of machinery, and by the light thrown on the processes by the progress of chemistry, the tedious methods of the Indians have been wonderfully simplified; and the processes are remarkable for the rapidity with which they are now executed, and for the beauty, fastness, and variety of the colours which are applied on the surface of cotton. So great have been these improvements, that at the present time in Manchester, a piece of calico can be printed in the short period of one minute; and the quantity of calicoes printed in Manchester in one year amounts to the extraordinary number of from 12,500,000 to 13,000,000.

The different processes to which the cotton cloth destined to be printed is subjected, are the following: singeing, bleaching, calendering, printing, washing, and finishing; or, in some instances, after having been printed, they are stoved, dunged, dyed, brightened, and finished.

The singeing is intended to remove the fibres of cotton which protrude on the surface of the cloth, and which is called "nap." This is done by passing the cloth rapidly over the surface of a red-hot iron plate, which burns off all the "nap" or protruding fibres of cotton without injuring the cloth. Of late years singeing has been effected by a very ingenious coal-gas apparatus, or by a mixture of hydrogen and oxide of carbon. But we need not dwell upon this preliminary process, because the *singeing* has been described already in this Encyclopædia under the article BLEACHING, to which we refer the reader.

We shall endeavour in this chapter to give a sketch of the different processes of calico-printing, such as they are at present practised by the most scientific printers in Lancashire, and in the neighbourhood of Glasgow.

Mousseline-de-laines.

Many of the calico-printers of the present day carry on a large trade in printing mousseline-de-laines, viz., fabrics which are composed of cotton and wool; but we shall not enter here into any special description of this branch of manufacture.

Methods of printing.

There are two modes of printing; namely, *block-printing* and *machine-printing*. The former has been practised from time immemorial; the latter is a modern invention, and originated after the introduction of the art of printing into Great Britain. The figure intended to be communicated to the cloth is cut out upon a block of sycamore, the parts which are to make the impression being left prominent, and the rest of the block cut away, just as practised for wood engravings. When the figure is too complicated, and the lines too fine, to admit of being cut in wood, it is made by means of small pieces of copper, which are very ingeniously driven into the block, and the interstices are filled up with felt.

Of late years several colours have been applied at once on the cloth by means of one block; and the machine used for this purpose is called a "toby," which consists of a box divided into several compartments filled with various colours, and which are in communication through tubes with bottles filled with the same colours; and by means of a gentle pressure the colouring fluid in each of the compartments of the machine is propelled through the felted cloth which covers each compartment. The block being pressed against the cloth, it takes the colour which is to be conveyed to the white calico by the block-printer.

Machine-printing.

Machine-printing is effected by one or several copper cylinders, of 3 feet 6 inches long, and about 6 inches in diameter, upon which the different figures to be given to the cloth are engraved. Each cylinder or roller is made to dip into a small box or trough containing the colour, discharge, mordant, or resist to be applied; and as the cylinder revolves and leaves the colour-trough, it is scraped by a steel blade called a "doctor," which takes off the excess of colour, and then it comes into contact with the white calico, passing between this roller and a larger one made of wood or cast-iron, and covered with felt, acting with pressure. By this means the exact figures on the engraved roller are printed on the cloth. To prevent the colours or mordants from dirtying or "running" into the whites, the printed pieces are immediately dried by passing them over tin cylinders, or flat cast-iron boxes, in which steam circulates. There are now machines in use having as many as 8 or 16 pairs of rollers, and which are technically called "8 or 16 colour machines," which implies that they are made to print 8 or 16 distinct colours successively on one piece of fabric. Another result of modern improvements is, that it only requires $1\frac{1}{2}$ minutes to print one piece, where it formerly required five minutes.

Perrotine machine.

On the Continent the intended figures are sometimes engraved upon a flat copper plate of about a square yard or more in size. Upon this plate the colour to be applied is spread. The plate is then pulled backwards, the excess of colour being removed by a "doctor," and the colour remaining on the engraving is then printed on the white cloth.

Whether the printing is applied by the block, the printing machine, or the perrotine, the treatment of the goods is nearly the same.

Most commonly the printing process consists merely in fixing mordants on the cloth, which is afterwards dyed in the common way, those parts only retaining the colour which have imbibed the mordant, while the other parts of the cloth remain white. Sometimes the substance called "a discharge" is applied to cloth already dyed, in order to remove the colour from certain portions of it which are either intended to remain white, or to receive some other colour afterwards.

Sometimes it is applied to cloth before it is dyed, in order to prevent the indigo, or any other colour, from being fixed on those parts to which it is applied, that they may remain white, or be afterwards made to receive other colours. Substances possessed of this property are called "resists."

Sometimes the cloth is mordanted with stannic acid, and the colours are then applied, and the whole submitted to the action of steam, and called "steamed goods." Finally, the printing process is frequently employed to communicate mordants and colouring matter at once to the cloth. Let us take a view of these different processes.

I.—*Mordants.*

The principal mordants employed by calico-printers are the following:—

How made.

1. *Alumina.*—The usual alumina mordant of the calico-printer is prepared by partly decomposing alum, held in solution by impure acetate of lime, commonly called pyrolignite of lime;[1] sulphate of lime precipitates, and aceto-sulphate of alumina is thus obtained. Red liquors thus prepared have a specific gravity of 1·08, and are composed as follows:—

Composition of four red Mordants per Gallon.

SUBSTANCES.	FORMULA. $Al^2O^3, So^3 + 2(C^4H^3O^3) + NH^3So^3\ HO$				FORMULA. $Al^2O^3, + 2So^3 + C^4H^3O^3 + NH^3, So^3, HO$		FORMULA. $Al^2O^3 + So^3, + 2(C^4H^3O^3)$	
	MORDANT A.		MORDANT B.		MORDANT C.		MORDANT D.	
	Grains.	oz. grs.	Grains.	oz. grs.	Grains.	oz. grs.	Grains.	oz. grs.
Alumina	1680 0	3 18	1830 0	4 19	1239 0	2 369	2164 4	4 416
Sulphuric Acid	2642 5	6 20	2800 0	6 178	3017 0	6 395	1664 6	3 323
Acetic Acid.....	3369 8	7 307	3970 0	8 70	1281 7	2 406	3679 2	8 179
Ammonia and Water........	674 1	1 236	910 0	2 35	693 1	1 215	...	...

[1] Pyrolignite of lime is obtained by neutralizing with lime impure vinegar obtained by the dry distillation of wood.

Calico-Printing.

In the manufacture of pyrolignite of alumina, or "red liquor," sulphate of alumina is frequently substituted for alum, and acetate of lead for pyrolignite of lime.

When cloth to be dyed *red or pink* is impregnated with this mordant, it is not thickened. When applied only to particular parts of the cloth by the block or the machine, it is thickened with flour or calcined farina, according to the nature of the style of work.

"Topical" colours.

2. *Perchloride of Tin.*—Perchloride of tin is very much used as a mordant. The colouring matter is previously mixed with it, and both are applied at once. Such applications are called "*topical" colours.* The mixture is allowed to dry on the cloth, which is then merely washed with water. Colours so applied are easily altered by light, soap, &c.

Hence a topical colour is one which is easily injured by exterior agents, and is commonly called, among printers, a "loose" colour. The colours produced in this way are pinks or reds, from peach or sapanwood; purples from logwood; yellows from quercitron bark or fustic; and greens from the last-mentioned dyes with the addition of Prussian blue.

Steam colours.

Perchloride of tin is much used in another process of calico-printing for producing what are technically known as "steam colours;" it is decomposed by an excess of caustic soda, and the peroxide of tin or stannic acid at first precipitated is re-dissolved, giving rise to stannate of soda.

The cloth is immersed in this liquid and dried, and the stannic acid is then precipitated upon the cloth by immersing it in a solution of sal-ammoniac or sulphate of magnesia, but most commonly in a solution of free sulphuric acid, and the pieces of calico are then washed and dried.

Some calico-printers use crystallized stannate of soda, dissolving it in water, and employing it as above described. The different colouring matters intended to be applied on such prepared cloth are generally mixed with a small proportion of sal-ammoniac, and sometimes with either salts of ammonia, salts of tin, or chlorate of potash, which are intended to give fixity and brilliancy to such colours. The colours are then thickened with starch and printed on the above-mentioned calico, and the whole is submitted to the action of steam. To effect this the calicoes are introduced into a square iron box called a "steam chest," and submitted to the influence of steam, a powerful oxidizing and fixing agent; or the printed cloths are rolled round a perforated roller and submitted to the same action. The pieces then only require to be well washed, dried, and finished, to be ready for the market.

The result of the combined action of moisture and heat is, that a combination takes place between the colouring principle and the peroxide of tin, or stannic acid, which renders the colouring matter insoluble. In this manner pinks, reds, purples, crimsons, yellows, oranges, blues, greens, browns, and drabs, are produced.

Oxides of iron;

3. *Oxides of Iron.*—These metallic oxides are much used as mordants, either in the state of protoxide or peroxide. The salt most employed is the impure pyrolignite of protoxide of iron, which is prepared either by decomposing green copperas with pyrolignite of lime, or by placing in large vats pyrolignous acid and old iron, when, after a few months, the iron, which is gradually oxidized, dissolves in the acid, and gives rise to pyrolignite of protoxide of iron.

how produced.

This valuable mordant is thickened with calcined farina,[1] and applied on the calico. After being exposed for a few days in a moist atmosphere, it loses a part of the acid, and becomes partially peroxidized. Pyrolignite of iron of the specific gravity of 1·05 gives a black with madder and several "tannin" substances. Various shades of purple are obtained by adding different proportions of water to the mordant previously to applying it to the cloth; and various shades of chocolates are produced by mixing this mordant with the alumina one previously described, and then dyeing also with madder. These are the principal mordants employed by the calico-printer. Several dyeing substances have so strong an affinity for calico that they require no mordant; this is the case with indigo, Prussian blue, safflower, peroxide of iron, sesquioxide of manganese, &c.

Purple.

Chocolate.

II.—*Substances used for Discharging Colours.*

Discharges

A discharge is a substance which has the property of removing a mordant, or destroying a colour so completely, that when the printed piece is properly washed no trace of either the mordant or the colour will be visible. In fact, the whites so produced will be as pure, or nearly so, as if no colour or mordant had been previously applied. And, as most colours are fixed on cloth either by means of mordants, or by oxidizing the colouring principle, hence the printers employ something that will dissolve the mordant in its normal state, or by deoxidizing it; but if no mordant be present, it will be by destroying the colouring matter through suroxidation or combustion, as is the case with chlorine, or with oxygen liberated from chromic acid. Therefore discharges employed are either acids, or substances having a strong oxidizing power.

their action.

1. *Citric Acid* is much used by printers to dissolve alumina and peroxide of iron, and thus to prevent the colours which these mordants would fix from remaining on the cloth. This discharge is obtained by using pure citric acid, or by evaporating lemon juice, and thickening it with gum-arabic, calcined starch, or farina for machine-printing; or with the same and pipe-clay for block-printing. It is occasionally assisted by bisulphate of potash or weak sulphuric acid.

Sometimes citric acid is printed on white cloth, and alumina or iron mordant, slightly thickened and dried immediately to prevent the swelling of the acid figures; at other times the mordants are first applied, and the acid printed over them.

In both cases the goods are afterwards passed through hot water containing cow's dung, and well washed before being dried. By these means all the mordant is removed from those parts on which the citric acid was applied, which, of course, remain white when the cloth is dried.

2. *Tartaric Acid,* thickened with gum, is applied by the block or printing machine to cloth previously dyed Turkey-red. It is then passed through an aqueous solution of bleaching powder, and the acid disengaging the chlorine, the red colour is discharged from those places to which it had been applied, while all the other parts of the cloth retain their red colour. Sometimes the Turkey-red calico is folded between metallic plates which are perforated with designs, and so arranged that each figure of the design corresponds through the pile of prints so folded. The whole is then submitted to pressure, and a chlorine liquor is forced by pressure to percolate through the mass, which destroys the red colour in all those parts where the perforated plates allowed the bleaching powder to circulate.

3. *Oxalic Acid*—To obtain white on indigo-blue "dips," the blue-dipped pieces of calico are printed with chromate of lead, and the pieces so prepared are passed through an

[1] Of late years gum arabic and tragacanth have been nearly entirely replaced by calcined farina, which is potato starch heated to a temperature of about 360° Fahrenheit, or until it has assumed a light buff colour and become soluble in cold water. "Purple gums" are the same, or wheat starch which has been mixed with a small percentage of weak nitric acid, and then a lower temperature is necessary to produce the conversion of the insoluble starch into a soluble gummy substance. "British gum" is a term applied to calcined wheat starch. "Flummery" is obtained in the manufacture of wheat starch, being found swimming as a scum on the surface. It is removed, drained by centrifugal force, and calcined.

Calico-Printing.

acid liquor composed of a solution of hydrochloric acid of a specific gravity of 1·050, and 1 ounce of oxalic acid per gallon. Chlorine is thus generated, and the blue indigo colouring matter, called indigotine, is destroyed in all those parts to which the chromate of lead was applied.

Protochloride of iron is sometimes used to discharge the manganese brown. This it does by depriving the oxide of manganese of a part of its oxygen, and thus renders it soluble; whilst the protoxide of iron, converted into a perchloride, deposits peroxide of iron on the cloth, which combines and produces the characteristic buff or orange colour of that oxide.

4. *Protochloride of tin*, when applied to cloth dyed brown by sesquioxide of manganese, immediately reduces it to the state of protoxide, and thus discharges the colour and leaves the parts white. If it be mixed with Brazil wood or cochineal, it discharges the manganese as before, but leaves a pink. When mixed with logwood, it leaves a purple, and with Prussian blue a blue. The protochloride of tin is used in a variety of ways in calico-printing to remove iron mordants, so as to prevent the colours fixing themselves in those parts which are intended to remain white.

The above organic acids, namely, citric, tartaric, and oxalic acids, are preferable to metallic discharges, as they not only remove the mordants which generally fix colours upon calico, but also because they leave no trace of their presence after they have fulfilled the objects for which they were employed; whilst, on the contrary, metallic discharges are apt to leave some sub-salt, which is easily produced when the water used by calico-printers is calcareous, and these traces of metallic salts are apt to dirty the whites.

III.—*Resist Pastes.*

Resists were first employed in China and India. They should possess the following general properties:—First, preventing effectually any colour or mordant from fixing on those parts of the cloth to which they have been previously applied, and at the same time of not injuring the colours which are to be subsequently employed. Secondly, resists should be of such a nature as to be easily removable by washing, after they have fulfilled their object.

Resists.

There are two distinct classes of reserves or resists, those which act by mechanically preventing the colour from reaching the cloth, and those which act chemically, by oxidizing the colour previously to its coming into contact with the fabric, and thus rendering it insoluble or incapable of fixing itself on the fibres of the fabric. A mixture of both these resists is often used.

Mechanical resists.

The resists which act in a purely mechanical manner, such as those composed of wax, resin, or tallow, are seldom resorted to, owing to the difficulty of ultimately removing them; but the use of pipe-clay, conjointly with a chemical resist, is very common. In "steam goods," mechanical resists are those chiefly used; they consist of arsenite or phosphate of lime, of phosphate of zinc and magnesia, or of acetate of lime and zinc.

1. *Blue resist* or *vitriol resist* consists of a mixture of sulphate, acetate, and sometimes nitrate of copper, and the solution is thickened with British gum, or calcined flummery, together with pipe-clay for the block, and flour for machine-printing. When the cloth on which this paste has been printed is dipped into an indigo vat, the indigo is oxidized before it reaches the surface of the cloth. (See BLUE.) After dyeing, the pieces are passed through weak sulphuric acid, not only to remove the oxide of copper, which has been precipitated, but also to fix the indigo on the calico, by liberating it entirely from its lime combination.

2. *Mild resist* consists of sulphate of zinc, flummery, and pipe-clay. It is used along with other colours which copper would injure, or which would be destroyed by immersion in sulphuric acid. It resists a pale-blue, and the removal of oxide of zinc afterwards by an acid is not necessary, as is the case when copper is employed.

3. *Red paste* consists of the alumina mordant above described, mixed with acetate of copper, and calcined British gum, or flummery and pipe-clay. It resists pale blues, and the alumina remains upon the portions of the cloth which are white, and which are to be afterwards dyed with madder to produce red, or with quercitron bark for yellow.

4. *Neutral resist* is a name given by calico-printers to a compound of lime juice,[1] sulphate of copper, British gum, and pipe-clay. It resists during a short dip in the indigo vat, and the lime juice gives it the property of remaining white when the piece is dyed in madder, even where the preceding alumina resist goes over it. This acid also prevents the lime of the blue indigo vats from precipitating copper upon the cloth, which would give it a deep-brown tinge in the madder beck.

5. *Chrome yellow resist* consists of a mixture of a salt of copper to resist the blue indigo vat, with a salt of lead to produce a chromate of lead, after having been dyed blue in the blue vat. (See *Blues.*)

These are the five principal resist pastes. There are a few others, but they will easily suggest themselves to those who understand the principles of chemistry.

"Conversion."

Besides the above methods, the process called "conversion," which has been discovered within the last few years, has proved a great acquisition to the calico-printer, as it enables him to increase the various effects which he may be desirous of producing on his prints. It consists in increasing or decreasing the tints of certain colours without affecting the whites; and this is effected by having a roller so disposed, that while one or two or more rollers are producing certain colours longitudinally, another roller will be printing transversely another colour, which in acting chemically on those printed longitudinally will alter their shades.

Instead of describing the method of printing mordants and colouring matters at once, or of applying "topical" colours, or of producing "steam colours," we think it will be better to make a few observations on each particular colour in succession, without distinguishing whether it is applied by dyeing or printing.

Reds and Pinks.

The most important dye stuff for producing red amongst calico-printers is madder. Goods which have received the alumina mordant as applied in figures, either by the machine or the block, are first hung, or "aged," as technically termed, for several days in large rooms. The purport of this operation is to allow the acetic acid to evaporate, and leave on the print a basic aceto-sulphate of alumina. The pieces are then passed through nearly boiling water, containing cow-dung, or a chemical substance, such as silicate or arseniate of soda, or a mixture called "Mercer's dung substitute." The pieces, after having been sufficiently "aged," are well washed and put into a dye-beck, containing water and madder; and the whole is gradually heated to 180° for two hours, and lastly, to boiling point for half an hour. The prints, having been kept constantly in motion during the above operation, and having assumed the required shades of pink and red, are washed and ready for a second series of operations, called "soaping" or clearing," which is effected by passing them for 25 minutes into a weak solution of soap, heated to about 185°, which substance has the property of removing the loose colours on the white parts, and of giving

[1] "Lime juice" is a commercial term applied to lemon juice, which is imported principally from Sicily, and from which also citric acid can be obtained.

brilliancy and fixity to the red and pink figures on the cloth. For certain styles of pinks, protochloride of tin is added to the soap. All madder colours require two soapings to give great brilliancy and vividness to the colours, and purity to the whites.

Of late years, madder has been nearly replaced in calico-printing by garancine[1] and garanceux, which have the property of yielding colours more brilliant than madder, although not so fast. But the chief reason why garancine has been substituted for madder is, because with it the prints, after they are dyed, require only a simple washing and no soaping to clear the whites.

Turkey red is one of the most beautiful and valuable styles of calico-printing, in consequence of the brilliancy of the colour and its durability. It is also obtained with madder, but the pieces previously to being dyed have to undergo a long series of operations, which consist in passing the pieces successively in Gallipoli oil and carbonate of soda, and hanging them in the air between each process. They are then passed into a weak solution of red mordant, and afterwards of gall-nuts, well washed, and dyed in madder. When this has been effected, the colours are brightened by being boiled, under pressure, in a solution of soap and chloride of tin.

When sapanwood or peachwood is used instead of madder or garancine, the mordant and method of dyeing are the same; the cloth, however, does not receive the same treatment after dyeing, and does not require it, because these colours are much more easily removed from the parts of the cloth which are destitute of mordant.

The chief employment of these dye-stuffs is in producing steam reds or pinks. To effect this, a decoction of these woods is mixed with chlorate of potash, nitrate of alumina, and thickened with wheat starch. This prepared colour is printed on calico which has been mordanted with stannic acid; and when dried it is ready to be introduced into a square iron box called a "steam-chest," and submitted to the action of an atmosphere of steam for 25 minutes, which has the property of fixing the colours on the cloth; or the printed calicoes are rolled round a perforated roller and submitted to the same influence. The pieces then only require to be well washed, dried, and finished, to be marketable.

Beautiful reds and pinks are produced by means of cochineal. The mordant is either alumina or oxides of tin, and the method of proceeding is similar to that already described for madder and garancine colours. Cochineal is also extensively employed to obtain these colours on steamed mousseline-de-laines.

Safflower cannot be applied to calico in figures, but it is frequently employed for giving numerous crimson or pink dyes to pieces of cloth. The safflower is first dipped into water containing carbonate of soda, which dissolves its colouring matter. The solution, freed from the fibrous part of the dye-stuff, is then saturated by impure citric acid, or lemon juice, otherwise lime juice. A piece of cloth immersed in this solution extracts the colouring matter from it, which is afterwards heightened by immersion in weak solution of cream of tartar. By this means a very beautiful but fugitive colour is communicated to calico.

Yellows and Oranges.

A fine yellow is produced by a very simple process, which was first introduced in calico-printing by Professor Thomson, which consisted in fixing on calico, especially blue indigo dips, a yellow or orange chromate of lead. To produce this well-known style, a reserve consisting of nitrate and sulphate of lead is printed, dried, and the pieces dyed in an indigo vat. They are then passed through weak sulphuric acid, and then into an alkaline chromate of potash, when orange chromate of lead designs are produced, or into a bichromate of potash, when yellow chromate of lead designs are raised.

Quercitron bark is also employed frequently to communicate a yellow colour to calicoes. The alumina mordant is first applied, and the cloth is passed in the dung-beck in the way described when giving an account of madder-dyeing. Quercitron bark yields its colouring matter at a lower temperature than madder; and the parts of the cloth to which no mordant has been applied remain tolerably white after the cloth has been washed in cold water.

Fustic is sometimes substituted for quercitron bark, but the yellow or orange colours which it produces are not so fast as those given by quercitron bark.

Persian berries.—A decoction of these berries constitutes likewise a yellow dye for calico-printers, and it may be employed in the same manner as the above substances, but generally it is used to produce steam yellows and oranges. For this purpose the decoction is mixed with oxalic acid, or a little acetate of alumina, and printed on calico prepared with stannic acid. For oranges the solution of Persian berries is mixed with chloride of tin in excess, and thickened with starch. The goods, after having been printed, are dried and steamed, and they only require washing in water.

Quercitron bark and fustic are sometimes used in cheap styles of prints as substitutes for Persian berries; but the yellows and oranges are rapidly injured by the atmosphere, which communicates to them a dirty brownish tint.

Buff.—To produce this colour the cloth is printed with a mixture of sulphate and pyrolignite of iron, or with nitro-sulphate of iron. After having had time to be partly oxidized and partly decomposed, it is washed in water; or if a stronger bath is wanted, it is raised in milk of lime till the protoxide of iron is converted into a sesquioxide. No mordant is required, as peroxide of iron has a strong affinity for cotton cloth. It is very easy to produce whites on such colour, all that is necessary being to print a discharge composed of oxalic and citric acids, which dissolve the hydrate of sesquioxide of iron, and leave those parts of the calico thus treated free of colour. Buff colours are also produced by printing an alkaline solution of annotto on calico prepared with stannic acid, and submitting it to the influence of steam.

Blue.

Not only the most ancient but also the most general means of obtaining blues on calicoes is by indigo, which is applied in various ways.

Indigo-blue dips.—This fine blue colour is produced by adding, in a vat capable of holding from 900 to 1000 gals. of water, 60 lbs. of finely ground indigo, to which is gradually added 140 lbs. of green copperas, or sulphate of protoxide of iron, together with 212 lbs. of slack lime. Owing to the lime removing the sulphuric acid from the salt of iron, the protoxide of that metal is liberated, and by its affinity for oxygen removes a part of the oxygen of the blue indigo, and thus transforms it into white indigo, which is soluble in the excess of lime employed in the operation. After the lapse of a few hours, the dye vat being ready, a piece of calico is hooked on a wooden frame and well stretched out; it is then dipped into the vat for 15 minutes, taken out and left exposed to the air for 5 minutes.

[1] Garancine is obtained by treating madder with weak sulphuric acid, and raising the whole to the boiling point for 2½ hours, then washing and submitting the charred mass to pressure. By this operation a chemical action ensues, and "alizarine," the colouring principle of madder, is produced, so that one part of garancine is equal to two parts of madder. Garanceux is prepared by a similar process, only commercial madder is replaced by madder which has been partly exhausted by having been previously employed for dyeing.

The piece of calico which is white when it comes out of the vat gradually becomes green, and then blue; owing to the oxygen of the air oxidizing the white indigo, transforming it into blue, which is insoluble in water, and fixed on the calico. The number of successive dips that the piece undergoes varies according to the various shades of blue which the printer requires. The pieces, after having been passed into a weak solution of sulphuric acid or "sours," which fixes the indigo thoroughly, only require to be well washed and dried.

To produce the well-known style of print which consists in a blue ground and white design, it is simply necessary to print the blue resist described above, passing the pieces in a vat containing lime, and then dyeing them in the above indigo vat. The pieces only require to be passed through vitriol, well washed and dried. We have also described the mode of obtaining oranges or yellows on such prints.

China blue.—This style of print is obtained by printing on the calico a mixture composed of pulverised indigo and sulphate of protoxide of iron, to which is sometimes added orpiment, and thickened with British gum. The pieces so printed are passed alternately, by means of rollers, first into a milk of lime, and then into a solution of sulphate of protoxide of iron; when there ensues one of the most interesting phenomena of calico-printing, for as fast as the blue indigo is reduced into white indigo, instead of being dissolved by the lime of the bath, it is retained with force through the molecular attraction of the fibre of the calico, and prevented leaving the cloth, until it is fixed by the exposure of the piece to the oxygen of the atmosphere. The pieces then only require to be passed into weak sulphuric acid, washed, and dried, in order to be completed.

Pencil blue is obtained by reducing blue into white indigo, by boiling it for several hours with protochloride of tin and alkali. When the indigo is well reduced, citrate of soda and starch are added; and after having carried the whole to the boiling-point, the calico is printed with it, passed into a milk of lime, washed, and dried.

Prussian blue may be applied to cloth in various ways. We shall mention some of the principal of these.

1. An iron mordant is first applied to the cloth, and allowed to remain untouched till the iron has had time to be partly peroxidized and become fixed. The pieces are then dipped into a solution of prussiate of potash, mixed with a little sulphuric acid, which acid liberates the prussic acid, which, in yielding its cyanogen to the iron of the oxides, produces cyanides of iron or Prussian blue. Sometimes the calico to be dyed is boiled for five hours in a solution of yellow prussiate, common salt, and chloride of tin, and afterwards into a second bath, containing sulphuric acid and alum; when Prussian blue is produced on the cloth, which only requires washing.

To produce white designs on such prints, it is usual to thicken with British gum a solution of caustic alkali, and to print it on all those parts of the cloth from which it is intended to discharge the colour. The pieces are then passed into a solution of oxalic or muriatic acid, well washed and dried.

2. *Prussian blue* is dissolved in muriatic acid, oxalic acid, perchloride of tin, or nitrate of iron, and the solution is applied to the cloth immediately in the usual way.

3. *Ferrocyanic acid* is printed upon cloth prepared with stannic acid, and decomposed under the influence of steam, in the ordinary steaming process; prussic acid escapes, and cyanides of iron, or Prussian blue, remains on the cloth. The blue is developed by exposure to the air, or by being passed through a weak solution of bleaching powder, or bichromate of potash.

4. Prussian blue is often obtained by printing prussiate of tin on prepared calico, and then submitting the print to the influence of steam.

Greens.

1. The fast green discovered by Mr James Thompson of Primrose Hill, near Clitheroe, Lancashire, and commonly known by the name of "Warwick's Green," is a mixture of the pencil blue already described and aluminate of potash. The mixture is thickened and applied in a similar way to the Prussian blue. The alumina is then precipitated from its alkaline solution, by being passed through a weak solution of sal-ammoniac or sulphate of magnesia. The cloth is then dyed yellow in quercitron bark. It is well known that blue and yellow form green. In this operation the alumina mordant can be replaced with advantage by oxide of tin.

2. The most common process followed to obtain green on prints, consists in printing, on prepared calico, prussiate of tin, together with Persian berries, and an alumina mordant, and subjecting such prints to the influence of steam. For producing a cheap style of prints, quercitron bark is often substituted for Persian berries; but the greens thus produced, though cheaper, are not fast.

3. *Arsenites of copper*, or "Scheele's greens." There are several modes of producing these greens on calicoes. The one most commonly employed consists in passing the cloth in a mixture of salts of copper, then into a weak solution of caustic lye, and lastly into a solution of arsenious acid. To obtain green patterns, the pieces are passed into an arsenite of soda, and then the salts of copper are printed on all those parts where green patterns are required.

Blacks.

1. Various methods are employed by the calico-printers to produce a black upon cotton. An iron mordant of the specific gravity of 1·05 gives a black with madder. The same mordant, mixed with "red liquor," gives a black when the cloth is passed through a hot solution of logwood. Great fixity has been imparted of late years to this black, as well as that produced with shumac, by passing the dyed pieces through a weak solution of bichromate of potash, which, in suroxidizing the colouring matter, completely fixes it on the fibres of the calico. No process in calico-printing is easier than to produce white designs on black; it is sufficient to print a mixture of oxalic and tartaric acids, thickened with calcined farina or starch, and passing through water. By this means the colour is discharged, owing to the iron mordant being dissolved, and the loosened colour washed away. By passing such pieces into an alumina mordant, and then into a beck containing sapanwood or peachwood, a red is produced; with logwood a purple, or with quercitron bark or fustic a yellow. Of late years, madder extract has been printed on such discharged blacks.

2. A topical black is made from a decoction of gallnuts, mixed with nitrate of peroxide of iron. Another topical black is produced by mixing a decoction of logwood with a solution of protoxide of iron, or of pyrolignite of iron.

Lilacs and Purples.

These colours are communicated to cloth by printing a diluted solution of pyrolignite of iron, thickened with calcined farina. The cloth is then dyed in madder exactly as described for producing reds. Steam lilacs and purples are obtained by thickening logwood with alumina mordant, or red liquor, and printing this mixture on calico prepared with stannic acid, and then submitting such prints to the influence of steam. Cochineal is sometimes substituted for logwood on mousseline-de-laines. Topical lilacs and purples are procured by printing a logwood solution previously mixed with perchloride of tin containing a little salts of iron.

Chocolates.

Various shades of chocolate are produced, as above stated, by printing on calicoes as mordant a mixture of pyrolignites of alumina and iron, and dyeing, as also described, in a madder beck.

Browns.

1. Of late years, browns and wood colours have been obtained extensively, by employing either a solution of catechu made with vinegar or weak alkali, and mixing it with salts of copper, iron, or tin, according to the shades required; and with sal-ammoniac for steam colours. To give fixity to such colours, the pieces, after having been printed and steamed or dyed, are passed into a weak solution of bichromate of potash or milk of lime.

2. By far the most fixed brown is communicated to cotton by means of the sesquioxide of manganese; but this process of producing browns has almost fallen into desuetude.

Drab.

This colour is procured by printing the cloth with an iron mordant, and then dyeing it in quercitron bark or shumac.

Olive.

This colour is formed by printing a mixture of iron and alumina mordants, and dyeing in quercitron bark or shumac.

Dove.

A weak iron mordant dyed in cochineal, sapanwood, or peachwood.

Finishing Processes.

After the prints have undergone the various operations which we have described, there is still another which they have to undergo to give them a finish—prints in their rough and uneven state being unmarketable. Consequently, they are submitted to a series of processes, whose object is to give to the fabrics such an appearance as will please the eye of the buyer, and obtain a better price in the market. All the finishing processes have one common end, namely, to fill up the interstices which exist between the fabrics, and thus give to the calico a more substantial and glossy appearance; and this is effected by filling the cloth with boiled starch, farina, or sour flour, which is obtained from wheat flour which has been allowed to ferment. To these are often added large quantities of sulphates of lime or baryta. To give a compact and glossy appearance to the surface of the cloth, it is passed between heated rollers under pressure; and according to the heat and pressure applied, so is the degree of lustre imparted to the fabric.

At other times the calico-printer gives little or no lustre to his fabrics; and in such cases the buyer, if he intends the goods for a foreign market, submits them himself to a process called "calendering," which consists in passing the pieces, either dried or slightly moistened, between heated rollers, and under high pressure. See Calender. (F.C.C.)

DYER, Sir James (1511–1582), an eminent English lawyer, who was at one time speaker of the House of Commons, and was afterwards chief judge of the court of common pleas in the reign of Elizabeth. He published a large collection of Reports, and several law tracts, which have been eulogized both by Coke and Camden.

Dyer, *John*, an English poet, the son of Robert Dyer, a Welsh solicitor of great ability, was born in 1700. He received his education at Westminster school under the care of Dr Freind, and was then called home to be instructed in his father's profession. His genius, however, soon led him to abandon the study of law; for besides his early taste for poetry, he had a passion no less strong for the arts of design, and determined to make painting his profession. With this view, having studied some time under a master, he became, as he himself narrates, an itinerant painter, and wandered about South Wales. About 1727 he printed *Grongar Hill*. Being probably dissatisfied with his own proficiency, he made the tour of Italy, where, besides the usual study of the remains of antiquity, and the works of the great masters, he frequently spent whole days sketching the picturesque scenery in the neighbourhood of Rome and Florence. Images drawn from thence naturally transferred themselves into his poetical compositions. The principal beauties of *The Ruins of Rome* are perhaps of this kind; and the description of various landscapes in *The Fleece* have been particularly admired. On his return to England he published *The Ruins of Rome,* 1740; but soon found that he could not relish a town life, nor submit to the assiduity required in his profession. Having been advised by his friends to enter into holy orders, he was ordained by the Bishop of Lincoln, and had a degree conferred on him.

About the same time he married a lady of Coleshill, named Ensor, "whose grandmother," says he, "was a Shakspeare, descended from a brother of every body's Shakspeare." His ecclesiastical provision was for a long time but slender. His first patron, Mr Harper, gave him, in 1741, Calthorpe, in Leicestershire, of L.80 a-year, on which he lived ten years; and in April 1751 he exchanged it for Belchford, in Lincolnshire, of L.75, which was given him by Lord Chancellor Hardwicke. His circumstances afterwards began to be more favourable. In 1752 Sir John Heathcoate gave him Coningsby, of L.140 a-year; and, in 1756, when he received the honorary degree of LL.B., he obtained from the chancellor, Kirby-on-Bane, of L.110. In 1757 he published *The Fleece*, his chief poetical work, of which Dr Johnson relates this ludicrous story. Dodsley the bookseller was one day mentioning it to a critical visitor, with more expectation of success than the other could easily admit. In the conversation the author's age was asked; and being represented as advanced in life, "He will," said the critic, "be buried in woollen." He did not indeed long outlive that publication, nor enjoy the increase of his preferments; for a consumptive disorder, with which he had long struggled, carried him off in 1758.

DYLE, a river of Belgium. See Belgium.

DYNAMETER, an instrument for ascertaining the magnifying power of telescopes, consists of a small tube with a transparent plate accurately divided. It is fixed to the tube of the telescope, in order to measure the diameter of the image of the eye-glass.

DYNAMICS.

Dynamics. Definition.

1. This name marks that department of physico-mathematical science which contains the abstract doctrine of *moving forces;* that is, whatever necessarily results from the relations of our ideas of motion, and of the immediate causes of its production and changes.

Object of dynamics is change of that condition of a thing which we call its *motion.*

2. All *changes* of motion are considered by us as the indications, the characteristics, and the measures of changing causes. This is a physical law of human thought, and therefore a principle to which we may refer, and from which we must derive all our knowledge of those causes. When we appeal to our own thoughts or feelings, we do not find in ourselves any disposition to refer mere existence to any cause, although the beginning of existence certainly produces this reference in an instant. Had we always observed the universe in motion, it does not appear that we should have ascribed it to a cause, till the observation of relative rest, or something leading to it, had enabled us to separate, by abstraction, the notion of matter from that of motion. We might then perceive that rest is not incompatible with matter; and we might even observe, by means of relative motions, that absolute rest might be produced by the concourse of equal and opposite motions. But all this requires reflection and reasoning, whereas we are now speaking of the first suggestions of our minds.

3. We cannot have any notion of motion *in abstracto,* without considering it as a state or condition of existence which would remain if not changed by some cause. It is from changes alone, therefore, that we infer any agency in nature; and it is in these that we are to find all that we know of their causes.

Mechanical relation, what.

4. When we look around us, we cannot but observe that the motions of bodies have in most cases, if not always, some relation to the situation, the distance, and the discriminating qualities of other bodies. The motions of the moon have a palpable relation to the earth; the motions of the tides have as evident a relation to the moon; the motions of a piece of iron have a palpable dependence on a magnet. The vicinity of the one seems to be the occasion at least of the motions of the other. The causes of these motions have an evident connection with or dependence on the other body. We are even disposed to imagine that they are inherent in that body, and that it possesses certain qualities which are the causes of those modifications of motion in other bodies. These serve to distinguish some bodies from others, and may therefore be called *properties;* and since the condition of other bodies so evidently depends on them, these properties express very interesting relations of bodies, and are chiefly attended to in the enumeration of the circumstances which ascertain what we call the *nature* of any thing. We do not mean to say that these inferences are always just; nay, we know that many of them are ill founded; but they are real, and they serve abundantly for informing us what we may expect from any proposed situation of things. It is enough for us to know, that when a piece of iron is so and so situated in relation to a magnet, it will move in a certain manner.

This mutual relation of bodies is differently considered, according to the interest that we chance to take in the phenomenon. The cause of the approach of the iron to a magnet is generally ascribed to the magnet, which is said to attract the iron, because we commonly employ the magnet in order that these motions may take place. The similar approach of a stone to the earth is ascribed to the stone, and we say that it tends to the earth. In all probability the procedure of nature is the same in both; for they are observed in every instance to be mutual between the related bodies. As iron approaches a magnet, so the magnet approaches the iron. The same thing is observed in the motions of electrified bodies; also in the case of the stone and the earth. Therefore the cause of the motions may be conceived as inherent in either, or in both.

Force and Action are figurative terms when used in mechanism.

The qualities thus inherent in bodies constituting their mechanical relations, have been called the *mechanical affections of matter.* But they are more commonly named *powers* or *forces;* and the event which indicates their presence is considered as the effect and mark of their agency. The magnet is said to *act* on the iron, the earth is said to *act* on the stone; and the iron and the stone are said to *act* on the magnet and on the earth.

All this is figurative or metaphorical language. All languages have begun with social union, and have improved along with it. The first collections of words expressed the most familiar and the most interesting notions. In the process of social improvement, the number of words did not increase in the same proportion with the notions that became interesting and familiar in their turn: for it often happened that relations of certain ideas so much resembled the relations of certain other ideas, that the word expressing one of them served very well for expressing the other; because the dissimilar circumstances of the two cases prevented all chance of mistake. Thus we are said to *surmount* a difficulty, without attaching to the word the notion of *getting over* a steep hill. Languages are thus filled with figurative expressions.

But the analogy is not in the force, but in the effect.

5. *Power, Force,* and *Action,* are words which must have appeared in the language of the most simple people; because the notions of personal ability, strength, and exertion, are at once the most familiar and the most interesting that can have a place in the human mind. These terms, when used in their pure, primitive sense, express the notions of the power, force, and action of a sentient, active being. Such a being only is an agent. The exertion of his power or force is (exclusively) action; but the relation of cause and effect so much resembles in its results the relation between this force and the work performed, that the same term may be very intelligibly employed for both. Perhaps the only case of pure unfigurative action is that of the mind on the body. But as this is always with the design of producing some change on external bodies, we think only of them; the instrument or tool is overlooked, and we say that we act on the external body. Our *real* action therefore is but the first movement in a long train of successive events, and is but the remote cause of the interesting event. The resemblance to such actions is very strong indeed in many cases of mechanical phenomena. A man throws a ball by the motion of his arm. A spring impels a ball in the same manner by unbending. These two events resemble each other in every circumstance but the action of the mind on the corporeal organ; the rest of it is a train of pure mechanism. In general, because the ultimate results of the mutual influence of bodies on each other greatly resemble the ultimate results of our actions on bodies, we have not invented appropriated terms, but have contented ourselves with those already employed for expressing our own actions, the exertions of our own powers or forces. The relation of physical cause and effect is expressed metaphorically in the words which belong properly to the relation of agent and action. This has been attended by the usual consequences of poverty

of language, namely, ambiguity, and sometimes mistake, both in our reflections (which are generally carried on by mental discourse), our reasonings, and our conclusions. It is necessary to be on our guard against such mistakes; for they frequently amount to the confounding of things totally different. Many philosophers of great reputation, on no better foundation than this metaphorical language, have confounded the relations of activity and of causation, and even denied that there is any difference; and they have affirmed that there is the same invariable relation between the determinations of the will and the inducements that prompt them, as there is between any physical power and its effect. Others have maintained that the first mover in the mechanical operations, and indeed through the whole train of any complicated event, is a percipient and intending principle, in the same manner as in our actions. According to these philosophers, a particle of gravitating matter perceives its relation to every other particle in the universe, and determines its own motion according to fixed laws, in exact conformity to its situation. But the language, and even the actions of all men, show that they have a notion of the relation of an agent to the action, easily distinguishable (because all distinguish it) from the relation between the physical cause and its effect. This metaphorical language has affected the doctrines of mechanical philosophy, and has produced a dispute about some of its first principles; the only way to decide this dispute is to avoid most scrupulously all metaphorical language, though at the expense of much circumlocution.

Directions for the safe employment of this analogy.

6. When we speak of powers or forces as residing in a body, and the effect as produced by their exertion, the body, considered as possessing the power, is said to *act* on the other. A magnet is said to act on a piece of iron; a billiard ball in motion is said to act on one that is hit by it; but if we attempt to fix our attention on this action, as distinct both from the agent and the thing acted on, we find no object of contemplation; the exertion or procedure of nature in producing the effect does not come under our view. When we *speak* of the action as distinct from the agent, we find that it is not the action, properly speaking, but the act, that we speak of. In like manner the action of a mechanical power can be conceived only in the effect produced.

Action implies change; and mere motion is not action.

7. A man is not said to act unless he produces some effect. Thought is the act of the thinking principle; motion of the limb is the act of the mind on it. In mechanics also, there is action only in so far as there is mechanical effect produced. I must act violently in order to begin motion on a slide. I must exert force, and this force exerted produces motion. I conceive the production of motion in all cases as the exertion of force; but it requires no exertion to continue the motion along the slide; I am conscious of none; therefore I ought to infer that no force is necessary for the continuation of any motion. The continuation of motion is not the production of any new effect, but the permanency of an effect already produced. We indeed consider motion as the effect of an action; but there would be no effect if the body were not moving. Motion is not the action, but the effect of the action.

Pression, impulsion.

8. Mechanical actions have been usually classed under two heads. They are either *pressures* or *impulsions*. They are generally considered as of different kinds—the exertions of different powers. *Pressure* is supposed to differ essentially from *impulse*.

Instead of attempting to define, or describe, these two kinds of forces and actions, we shall just mention some instances. This will give us all the knowledge of their distinctions that we can acquire.

Examples of pression.

When a ball lies on a table, and I press it gently on one side, it moves toward the other side of the table. If I follow it with my finger, continuing my pressure, it accelerates continually in its motion. In like manner, when I press on the handle of a common kitchen jack, the fly *begins* to move. If I continue to urge or press round the handle, the fly accelerates continually, and may be brought into a state of very rapid motion. These motions are the effects of genuine pressure. The ball would be urged along the table in the same manner, and with a motion continually accelerated, by the unbending of a spring. Also, a spring coiled up round the axis of the handle of the jack would, by uncoiling itself, urge round the fly with a motion accelerating in the same way. The more I reflect on the pressure of my finger on the ball, and compare it with the effect of the spring on it, the more clearly do I see the perfect similarity; and I call these influences, exertions, or actions, by one name, *pressure*, taken from the most familiar instance of them.

Again, the very same motion may be produced in the ball or fly, by pulling the ball or the machine by means of a thread, to which a weight is suspended. As both are motions accelerated in the same manner, I call the influence or action of the thread on the ball or machine by the same name, *pressure*, and *weight* is considered as a pressing power. Indeed I feel the same compression from the real pressure of a man on my shoulders that I would feel from a load laid on them. But the weight in our example is acting by the intervention of the thread. By its pressure it is pulling at that part of the thread to which it is fastened; this part is pulling at the next by means of the force of cohesion; and this pulls at a third, and so on, till the most remote pulls at the ball or the machine. Thus may elasticity, weight, cohesion, and other forces, perform the office of a genuine power; and since their result is always a motion beginning from nothing, and accelerating by perceptible degrees to any velocity, this resemblance makes us call them by one familiar name.

But further, I see that if the thread be cut, the weight will fall with an accelerated motion, which will increase to any degree, if the fall be great enough. I ascribe this also to a pressing power acting on the weight. Nay, after a very little refinement, I consider this power as the cause of the body's weight; which word is but a distinguishing name for this particular instance of pressing power. Gravitation is therefore added to the list of pressures; and for similar reasons the attractions and repulsions of magnets or electric bodies may be added to the list; for they produce actual compressions of bodies placed between them, and they produce motions gradually accelerated, precisely as gravitation does. Therefore all these powers may be distinguished by this descriptive name, *pressures*, which, in strict language, belongs to one of them only.

Gravity, attractions, and repulsions, are considered as pressions.

Several writers, however, subdivide this great class into pressions and solicitations. Gravity is a solicitation *ab extra*, by which a body is urged downward. In like manner the forces of magnetism and electricity, and a vast variety of other attractions and repulsions, are called *solicitations*. We see little use for this distinction, and the term is too like an affection of mind.

Examples of impulsion.

9. *Impulsion* is exhibited when a ball in motion puts another ball into motion by hitting, or (to speak metaphorically) by striking it. The appearances here are very different. The body that is struck acquires, in the instant of impulse, a sensible quantity of motion, and sometimes a very rapid motion. This motion is neither accelerated nor retarded after the stroke, unless it be affected by some other force. It is also remarked that the rapidity of the motion depends, *inter alia*, on the previous velocity of the striking body. For instance, if a clay ball,

moving with any velocity, strike another equal ball which is at rest, the struck ball moves with half the velocity of the other. And it is farther remarkable that the striking body always loses as much motion as the struck body gains. This universal and remarkable fact seems to have given rise to a confused or indistinct notion of a sort of transference of motion from one body to another. The phraseology in general use on this subject expresses this in the most precise terms. The one ball is not said to cause or produce motion in the other, but to *communicate* motion to it; and the whole phenomenon is called the *communication of motion*. We call this an *indistinct* notion; for surely no one will say that he has any clear conception of it. We can form the most distinct notion of the communication of heat, or of the cause of heat: of the communication of saltness, sweetness, and a thousand other *things;* but we cannot conceive how part of that identical motion which was formerly in A, is now infused into B, being given up by A. It is in our attempt to form this notion that we find that motion is not a *thing*, not a substance which can exist independently, and is susceptible of actual transference. It appears in this case to be a state, or condition, or mode of existence, of which bodies are susceptible, which is producible, or (to speak without metaphor) causable, in bodies, and which is the effect and *characteristic* of *certain* natural qualities, properties, or powers. We are anxious to have our readers impressed with clear and precise notions on this subject, being confident that such, and only such, will carry them through some intricate paths of mechanical and philosophical research.

Communication of motion not a good expression.

Inherent force is the distinctive character of impulsion,

10. The remarkable circumstance in this phenomenon is, that a rapid motion, which requires for the effecting it the action of a pressing power, continued for a sensible, and frequently a long time, seems to be affected in an instant by impulsion. This has tended much to support the notion of the actual transference of something formerly possessed exclusively by the striking body, inhering in it, but separable, and now transfused into the body stricken. And now room is found for the employment of metaphor, both in thought and language. The *striking* body affects the body which it thus impels: it therefore possesses the *power* of impulsion, that is, of *communicating* motion. It possesses it only while it is in motion. This *power*, therefore, is the efficient distinguishing cause of its motion, and its only office must be the continuation of this motion. It is therefore called the *inherent force*, the force inherent in a moving body, VIS INSITA *corpori moto.* This force is transfused into the body impelled; and *therefore* the transference is instantaneous, and the impelled body continues its motion till it is changed by some other action. All this is at first sight very plausible; but a scrupulous attention to those feelings which have given rise to this metaphorical conception should have produced very different notions. I am conscious of exertion in order to begin motion on a slide; but if the ice be very smooth, I am conscious of no exertion in order to slide along. My power is felt only while I am conscious of exerting it; therefore I have no primitive feeling or notion of power while I am sliding along. I am certain that no exertion of power is necessary here. Nay, I find that I cannot think of my moving forward without effort otherwise than as a certain mode of my existence. Yet we imagine that the partizans of this opinion did really deduce it in some shape from their feelings. We must continue the *exertion* of walking in order to walk on; our power of walking must be continually exerted, otherwise we shall stop. But this is a very imperfect, incomplete, and careless observation. Walking is much more than mere continuance in progressive motion. It is a continually repeated lifting our body up a small height, and allowing it to come down again. This renewed ascent requires repeated exertion.

and said to be infinitely greater than pression.

11. We have other observations of importance yet to make on this force of moving bodies, but this is not the most proper occasion. Meanwhile we must remark, that the instantaneous production of rapid motion by impulse has induced the first mechanicians of Europe to maintain that the power or force of impulse is unsusceptible of any comparison with a pressing power. They have asserted that impulse is infinitely great when compared with pressure; not recollecting that they held them to be things totally disparate, that have no proportion more than weight and sweetness. But these gentlemen are perpetually enticed away from their creed by the similarity of the ultimate results of pressure and impulse. No person can find any difference between the motion of two balls moving equally swift, in the same direction, one of which is descending by gravity, and the other has derived its motion from a blow. This struggle of the mind to maintain its faith, and yet accommodate its doctrines to what we see, has occasioned some other curious forms of expression. Pressure is considered as an *effort* to produce motion. When a ball lies on a table, its weight, which they call a *power*, continually and repeatedly *endeavours* (mark the metaphorical word and thought) to move the ball downward. But these efforts are ineffectual. They say that this ineffectual power is *dead*, and call it a *vis mortua:* but the force of impulsion is called a *vis viva*, a living force. But this is very whimsical and very inaccurate. If the impelling ball falls perpendicularly on the other lying on the table, it will produce no motion, any more than gravity will; and if the table be annihilated, gravity becomes a *vis viva*.

Arguments indistinct and inconclusive.

We must now add, that in order to prove that impulse is infinitely greater than pressure, these mechanicians turn our attention to many familiar facts which plead strongly in their favour. A carpenter will drive a nail into a board with a very moderate blow of his hammer. This will require a pressure which seems many hundred times greater than the impelling effort of the carpenter. A very moderate blow will shiver into pieces a diamond which would carry the weight of a mountain. Seeing this prodigious superiority in the impulse, how shall they account for the production of motion by means of pressure; for this motion of the hammer might have been acquired by its falling from a height; nay, it is actually acquired by means of the continued pressure of the carpenter's arm. They consider it as the aggregate of an infinity of succeeding pressures in *every* instant of its continuance; so that the insignificant smallness of each effort is compensated by their inconceivable number.

No difference between pression and impulsion.

On the whole, we do not think that there is clear evidence that there are two kinds of mechanical force essentially different in their nature. It is virtually given up by those who say that impulse is infinitely greater than pressure. Nor is there any considerable advantage to be obtained by arranging the phenomenon under those two heads. We may perhaps find some method of explaining satisfactorily the remarkable difference that is really observed in the two modes of producing motion; namely, the gradual production of motion by acknowledged pressure, and the instantaneous production of it by impulse. Indeed we should not have taken up so much of our readers' attention with this subject, had it not been for some inferences that have been made from these premises, which meet us in our very entry on the consideration of first principles, and that are of extensive influence on the whole science of mechanical philosophy, and, indeed, on the whole study of nature.

Is impulsion the sole cause of motion?

12. Mechanicians are greatly divided in their opinion about the nature of the sole moving force in nature. Those whom we are now speaking of seem to think that all motion is produced by pressure; for when they consider impulse as equivalent to the aggregate of an infinity of repeated pressures, they undoubtedly suppose any pressure, however insignificant, as a moving force. But there is a party, both numerous and respectable, who maintain that impulsion is the sole cause of motion. We see bodies in motion, say they, and we see them impel others; and we see that this production of motion is regulated by such laws, that there is but one absolute quantity of motion in the universe which remains unalterably the same. It must therefore be transfused in the acts of collision. We also see, with clear evidence, in some cases, that motion can produce pressure. Euler adduces some very whimsical and complicated cases, in which an action precisely similar to pressure may be produced by motion. Thus, two balls connected by a thread may be so struck that they shall move forward, and at the same time wheel round. In this case the connecting thread will be stretched between them. Now, say the philosophers, since we see motion, and see that pressure may be produced by motion, it is preposterous to imagine that it is any thing else than a result of certain motions; and it is the business of a philosopher to inquire and discover what motions produce the pressures that we observe.

They then proceed to account for those pressing powers, or solicitations to motion, which we observe in the acceleration of falling bodies, the attractions of magnetism and electricity, and many other phenomena of this kind, where bodies are put in motion by the vicinity of other bodies, or, in the popular language, by the action of other bodies at a distance. To say that a magnet can act on a piece of remote iron, is to say that it can act *where* it is not, which is as absurd as to say that it can act *when* it is not. *Nihil movetur*, says Euler, *nisi a contiguo et moto.*

How does it produce pressure?

The bulk of these philosophers are not very anxious about the way in which these motions are produced, nor do they fall upon such ingenious methods of producing pressure as the one already mentioned, which was adduced by Euler. The piece of iron, say they, is put in motion when brought into the neighbourhood of a magnet, because there is a stream of fluid issuing from one pole of the magnet, which circles round the magnet, and enters at the other pole. This stream impels the iron, and arranges it in certain determined positions, just as a stream of water would arrange the flote grass. In the same manner, there is a stream of fluid continually moving towards the centre of the earth, which impels all bodies in lines perpendicular to the surface; and so on with regard to other like phenomena. These motions are thus reduced to very simple cases by impulsion.

Incompatible with the rules of philosophising.

It is unnecessary to refute this doctrine at present: it is enough that it is contrary to all the dictates of common sense. To *suppose* an agent that we do not see, and for whose existence we have not the smallest argument; with equal propriety we might suppose ministering spirits, or any thing that we please.

Others maintain that pressure is the sole moving force.

13. Other philosophers are so dissatisfied with this notion of the production of pressure, that they, on the other hand, affirm that pressure is the only moving force in nature; not according to the popular notion of pressure, by the mutual contact of solid bodies, but that kind of pressure which has been called *solicitation*, such as the power of gravity. They affirm that there is no such thing as contact on instantaneous communication of motion by real collision. They say, and they prove it by very convincing facts, that the particles of solid bodies exert very strong repulsions to a small distance; and therefore, when they are brought by motion sufficiently near to another body, they repel it, and are equally repelled by it. Thus is motion produced in the other body, and their own motion is diminished. And they then show, by a scrupulous consideration of the state of the bodies while the one is advancing and the other retiring, in what manner the two bodies attain a common velocity, so that the quantity of motion before collision remains unchanged, the one body gaining as much as the other loses. They also show cases of such mutual action between bodies, where it is evident that they have never come into contact; and yet the result has been precisely similar to those cases where the motion appeared to be changed in an instant. Therefore they conclude that there is no such thing as instantaneous *communication*, or transfusion of motion, by contact in collision or impulse. The reason why previous motion of the impelling body is necessary, is not that it may have a *vis insita corpori moto*, a force inherent in it *by its being in motion*, but that it may continue to follow the impelled and retiring body, and exert on it a force inherent in itself, whether in motion or at rest. According to these philosophers, therefore, all moving forces are of that kind which has been named *solicitation*, such as gravity. We shall know it afterwards by the more familiar and descriptive name of *accelerating* or *retarding* force.

Action, resistance, re-action.

14. The exertions of mechanical forces are differently termed, according to the reference that we make to the result. If in boxing or wrestling I strike, or endeavour to throw my antagonist, I am said to *act;* but if I only parry his blows, or prevent him from throwing me, I am said to *resist.* This distinction is applied to the exertions of mechanical powers. When one body, A, changes the motion of another, B, we may consider the change in the motion of B either as the indication and measure of A's power of producing motion, or as the indication and measure of A's resistance to the being brought to rest, or having its motion any how changed. The distinction is not in the thing itself, but only in the reference that we are disposed, by other considerations, to make of its effect. They may be distinguished in the following manner: If a change of motion follow when one of the powers ceases to be exerted, that power is conceived as having resisted. The whole language on this subject is metaphorical. Resistance, effort, endeavour, &c. are words which cannot be employed in mechanical discussions without figure, because they all express notions which relate to sentient beings; and the unguarded indulgence of this figurative language has so much affected the imagination of philosophers, that many have almost animated all matter. Perhaps the word *reaction*, introduced by Newton, is the best term for expressing that mutual force which is perceived in all the operations of nature that we have investigated with success. As the magnet attracts iron, and in so doing is said to *act* on it; so the iron attracts the magnet, and may be said to *re-act* on it.

We need not suppose action at a distance. Tendency

15. With respect to the difficulty that has been objected to the opinion of those who maintain that all the mechanical phenomena are produced by the agency of attracting or repelling forces; namely, that this supposes the bodies to act on each other at a distance, however small those distances may be, which is thought to be absurd, we may observe, that we may ascribe the mutual approaches or recesses to tendencies to or from each other. What we call *the attraction of the magnet* may be considered as a tendency of the iron to the magnet, somewhat similar to the gravitation of a stone toward the earth. We surely (at least the unlearned) can and do conceive the iron to be affected by the magnet, *without thinking* of any intermedium. The thing is not therefore inconceivable, which is all that we know about absurdity; and we do not

Dynamics. know any thing about the nature or essence of matter which renders this tendency to the magnet impossible. That we do not see intuitively any reason why the iron should approach the magnet, must be granted; but this is not enough to entitle us to say that such a thing is impossible, or inconsistent with the nature of matter. It appears, therefore, to be very hasty and unwarrantable to suppose the impulse of an invisible fluid, of which we know nothing, and of the existence of which we have no proof. Nay, if it be true that bodies do not come into contact, even when one ball hits another, and drives it before it, this invisible fluid will not solve the difficulty, because the same difficulty occurs in the action of any particle of the fluid on the body. We are obliged to say that the production of motion without any *observed* contact, is a much more familiar phenomenon than the production of motion by impulsion. More motion has been produced in this way by the gravitation of a small stream of water, running ever since the creation, than by all the impulses in the world twice told. We do not mean by this to say, that the giving to this observed mutual relation between iron and a loadstone the name *tendency* makes it less absurd than when we say that the loadstone attracts the iron; it only makes it more conceivable. It suggests a very familiar analogy; but both are equally figurative expressions, at least as the word tendency is used at present. In the language of ancient Rome, there was no metaphor when Virgil's hero said, *Tendimus in Latium. Tendere versus solem* means, in plain Latin, to *approach the sun*. The safe way of conceiving the whole is to say that the condition of the iron depends on the vicinity of the magnet.

Attraction, repulsion, are figurative terms.

16. When the exertions of a mechanical power are observed to be always directed toward a body, that body is said to attract; but when the other body always moves off from it, it is said to repel. These also are metaphorical expressions. I attract a boat when I pull it toward me by a rope; this is purely *Attraction:* and it is pure, unfigurative *Repulsion*, when I push any body from me. The same words are applied to the mechanical phenomena, merely because they resemble the results of real attraction or repulsion. We must be much on our guard to avoid metaphor in our conceptions, and never allow those words to suggest to our mind any opinion about the *manner* in which the mechanical forces produce their effects. It is plain, that if the opinion of those who maintain the existence and action of the above-mentioned invisible fluid be just, there is nothing like attraction or repulsion in the universe. We must always recur to the simple phenomenon, the motion to or from the attracting or repelling body; for this is all we see, and generally all that we know.

Forces are conceived as measurable quantities.

17. We conceive one man to have twice the strength of another man, when we see that he can withstand the united effort of two others. Thus animal force is conceived as a quantity, made up of and measured by its own parts. But we doubt exceedingly whether this be an accurate conception. We have not a distinct notion of one strain added to another, though we have of their being joined or combined. We want words to express the difference of these two notions in our own minds, but we imagine that others perceive the same difference. We conceive clearly the addition of two lines or of two minutes; we can conceive them apart, and perceive their boundaries, common to both, where one ends and the other begins. We cannot conceive thus of two forces combined; yet we cannot say that two equal forces are *not* double of one of them. We measure them by the effects which they are known to produce. Yet there are not wanting many cases where the action of two men, equally strong, does not produce a double motion.

In like manner, we conceive all mechanical forces as measurable by their effects; and thus they are made the subjects of mathematical discussion. We talk of the proportions of gravity, magnetism, electricity, &c.; nay, we talk of the proportion of gravity to magnetism: yet these, considered in themselves, are disparate, and do not admit of any proportion; but they produce effects, some of which are measurable, and whose assumed measures are susceptible of comparison, being quantities of the same kind. Thus, one of the effects of gravity is the acceleration of motion in a falling body: magnetism will also accelerate the motion of a piece of iron; these two accelerations are comparable. But we cannot compare magnetism with heat, because we do not know any measurable effects of magnetism that are of the same kind with any effects of heat. Dynamics. How measured.

When we say that the gravitation of the moon is the 3600th part of the gravitation at the sea-shore, we mean that the fall of a stone in a second is 3600 times greater than the fall of the moon in the same time. But we also mean (and this expresses the proportion of the *tendency* of gravitation more purely), that if a stone, when hung on a spring steelyard, draw out the rod of the steelyard to the mark 3600, the same stone, taken up to the distance of the moon, will draw it out no farther than the mark 1. We also mean, that if the stone at the sea-shore draw out the rod to any mark, it will require 3600 such stones to draw it out to that mark when the trial is made at the distance of the moon. It is not, therefore, in consequence of any immediate perception of the proportion of the gravitation at the moon to that at the surface of the earth that we make such an assertion; but these motions, which we consider as its effects in these situations, being magnitudes of the same kind, are susceptible of comparison, and have a proportion which can be ascertained by observation. It is these proportions that we contemplate; although we speak of the proportions of the unseen causes, the forces, or endeavours to descend. It will be of material service to the reader to peruse the judicious and acute dissertation on *quantity* in the works of Dr Reid (vol. ii.), where he will see clearly how force, velocity, density, and many other magnitudes of very frequent occurrence in mechanical philosophy, may be made the subjects of mathematical discussion, by means of some of those proper quantities, measurable by their own parts, which are to be assumed as their measures. Pressures are measurable only by pressures. When we consider them as moving powers, we should be able to measure them by *any* moving powers, otherwise we cannot compare them; therefore it is not as pressures that we then measure them. This observation is momentous. By their effects.

One circumstance must be carefully attended to. That those assumed measures may be accurate, they must be invariably connected with the magnitudes which they are employed to measure, and so connected that the degrees of the one must change in the same manner with the degrees of the other. This is evident, and is granted by all. But we must also *know* this of the measure we employ; we must see this constant and precise relation. How can we know this? We do not perceive force as a separate existence, so as to see its proportions, and to see that these are the same with the proportions of the measures, in the same manner that Euclid sees the proportions of triangles and those of their bases, and that these proportions are the same when the triangles are of equal altitudes. How do we discover that to every magnitude which we call *force* is invariably attached a corresponding magnitude of acceleration or deflection? Clearly. In fact, the very existence of the force is an inference that we make from the observed acceleration; and the degree of

Dynamics.

the force is, in like manner, an inference from the observed magnitude of the acceleration. Our measures are therefore necessarily connected with the magnitudes which they measure, and their proportions are the same; because the one is always an inference from the other, both in species and in degree.

Dynamics is a demonstrative science.

18. It is now evident that these disquisitions are susceptible of mathematical accuracy. Having selected our measures, and observed certain mathematical relations of those measures, every inference that we can draw from the mathematical relations of the proportions of those representations is true of the proportions of the motions, and therefore of the proportions of the forces. And thus dynamics becomes a demonstrative science, one of the *disciplinæ accuratæ*.

19. But moving forces are considered as differing and in kind; that is, in direction. We assign to the force the direction of the observed change of motion, which is not only the indication, but also the characteristic, of the changing force. We call it an *accelerating*, *retarding*, *deflecting force*, according as we observe the motion to be accelerated, retarded, or deflected.

These denominations show us incontestably that we have no knowledge of the forces different from our knowledge of the effects. The denominations are all either descriptive of the effects, as when we call them accelerating, penetrating, protrusive, attractive, or repulsive forces; or they are names of reference to the substances in which the accelerating, protrusive, &c. forces are supposed to be inherent, as when we call them *magnetism*, *electricity*, *corpuscular*, &c.

Forces are discovered by their opposition to other forces.

20. When I struggle with another, and feel, that in order to prevent being thrown, I must exert force, I learn that my antagonist is exerting force. This motion is transferred to matter; and when a moving power which is *known* to operate produces no motion, we conceive it to be opposed by another equal force, the existence, agency, and intensity of which is detected and measured by these means. The quiescent state of the body is considered as a change on the state of things that would have been exhibited in consequence of the known action of one power, had this other power not acted; and this change is considered as the indication, characteristic, and measure, of another power, detected in this way. Thus forces are recognised not only by the changes of motion which they produce, but also by the changes of motion which they prevent. The cohesion of matter in a string is inferred not only by its giving motion to a ball which I pull toward me by its intervention, but also by its suspending that ball, and hindering it from falling. I know that gravity is acting on the ball, which, however, does not fall. The solidity of a board is equally inferred from its stopping the ball which strikes it, and from the motion of the ball which it drives before it. In this way we learn that the particles of tangible matter cohere by means of moving forces, and that they resist compression with force; and in making this inference, we find that this corpuscular force exerted between the particles is mutual, opposite, and equal; for we must apply force equally to *a* or to *b*, in order to produce a separation or a compression. We learn their equality, by observing that no motion ensues while these mutual forces are known to act on the particles; that is, each is opposed by another force, which is neither inferior nor superior to it.

OF THE LAWS OF MOTION.

Such, then, being our notions of mechanical forces, the causes of the sensible changes of motion, there will result certain consequences from them, which may be called axioms or laws of motion. Some of these may be intuitive, offering themselves to the mind as soon as the notions which they involve are presented to it. Others may be as necessary results from the relations of these notions, but may not readily offer themselves without the mediation of axioms of the first class. We shall select those which are intuitive, and may be taken for the first principles of all discussions in mechanical philosophy.

First Law of Motion.

FIRST LAW OF MOTION.

Every body continues in a state of rest, or of uniform rectilineal motion, unless affected by some mechanical force.

21. This is a proposition, on the truth of which the whole science of mechanical philosophy ultimately depends. It is therefore to be established on the firmest foundation; and a solicitude on this head is the more justifiable, because the opinions of philosophers have been extremely different, both with respect to the truth of this law, and with respect to the foundation on which it is built. These opinions are, in general, very obscure and unsatisfactory; and, as is natural, they influence the discussions of those by whom they are held through the whole science. Although of contradictory opinions one only can be just, and it may appear sufficient that this one be established and uniformly applied; yet a short exposition, at least, of the rest is necessary, that the greatest part of the writings of the philosophers may be intelligible, and that we may avail ourselves of much valuable information contained in them, by being able to perceive the truth in the midst of their imperfect or erroneous conceptions of it.

Does continued motion indicate continued action?

22. It is not only the popular opinion that rest is the natural state of body, and that motion is something foreign to it, but it has been seriously maintained by the greatest part of those who are esteemed philosophers. They readily grant that matter will continue at rest unless some moving force act upon it. Nothing seems necessary for matter's remaining where it is, but its continuing to exist. But it is far otherwise, say they, with respect to matter in motion. Here the body is continually changing its relations to other things; therefore the continual agency of a changing cause is necessary (by the fundamental principle of all philosophical discussion), for there is here the continual production of an effect. They say that this metaphysical argument receives complete confirmation (if confirmation of an intuitive truth be necessary) from the most familiar observation. We see that all motions, however violent, terminate in rest, and that the continual exertion of some force is necessary for their continuance.

Whimsical notion of elemental minds.

23. These philosophers therefore assert, that the continual action of the moving cause is *essentially* necessary for the continuance of the motion; but they differ among themselves in their notions and opinions about this cause. Some maintain that all the motions in the universe are produced and continued by the immediate agency of Deity; others affirm, that in every particle of matter there is inherent a sort of mind, the φυσις and ὁσπερ ψυχη of Aristotle, which they call an *Elemental Mind*, which is the cause of *all* its motions and changes. An overweening reverence for Greek learning has had a great influence in reviving this doctrine of Aristotle. The Greek and Roman languages are affirmed to be more accurate expressions of human thought than the modern languages are. In those ancient languages, the verbs which express motion are employed both in the active and passive voice; whereas we have only the active verb *to move*, for expressing both the state of motion and the act of putting in motion. "The stone *moves* down the slope, and *moves* all the pebbles which lie in its way;" but in the ancient lan

First Law of Motion.

guages, the mere state of motion is always expressed by the passive or middle voice. The accurate conception of the speakers is therefore extolled. The state of motion is expressed as it ought to be, as the result of a continual action. Κινειται, *movetur*, is equivalent to "it is moved." According to these philosophers, every thing which *moves* is mind, and every thing that *is moved* is body.

The argument is futile, and it is false; for the modern languages are, in general, equally accurate in this instance: "*se mouvoir*," in French; "*sich bewegen*," in German; "*dvigatsu*," in Slavonic; are all passive or reflected. And the ancients said that "rain falls, water runs, smoke rises," just as we do. The ingenious author of *Ancient Metaphysics* has taken much pains to give us, at length, the procedures of those elementary minds in producing the ostensible phenomena of local motion; but it seems to be merely an abuse of language, and a very frivolous abuse. This elemental mind is known and characterised only by the effect which we ascribe to its action; that is, by the motions or changes of motions. Uniform and unexcepted experience shows us that these are regulated by laws as precise as those of mathematical truth. We consider nothing as more fixed and determined than the common laws of mechanism. There is nothing here that indicates any thing like spontaneity, intention, purpose; none of those marks by which mind was first brought into view; but they are very like the effects which we produce by the exertions of our corporeal forces; and we have accordingly given the name *force* to the causes of motion. It is surely much more apposite than the name mind, and conveys with much more readiness and perspicuity the very notions that we wish to convey.

Action not necessary for the continuance of motion.

24. We now wish to know what reason we have to think that the continual action of some cause is necessary for continuing matter in motion, or for thinking that rest is its natural state. If we pretend to draw any argument from the nature of matter, that matter must be known, as far as is necessary for being the foundation of argument. Its very existence is known only from observation; all our knowledge of it must therefore be derived from the same source.

If we take this way to come at the origin of this opinion, we shall find that experience gives us no authority for saying that rest is the natural condition of matter. We cannot say that we have ever seen a body at rest; this is evident to every person who allows the validity of the Newtonian philosophy, and the truth of the Copernican system of the sun and planets; all the parts of this system are in motion. Nay, it appears from many observations, that the sun, with his attending planets, is carried in a certain direction, with a velocity which is very great. We have no unquestionable authority for saying that any one of the stars is absolutely fixed; but we are *certain* that many of them are in motion. Rest is therefore so rare a condition of body, that we cannot say, from any experience, that it is its natural state.

25. It is easy, however, to see that it is from observation that this opinion has been derived; but the observation has been limited and careless. Our experiments in this sublunary world do indeed always require continued action of some moving force to continue the motion; and if this be not employed, we see the motions slacken every minute, and terminate in rest after no long period. Our first notions of sublunary bodies are indicated by their operation in cases where we have some interest. Perpetually seeing our own exertions necessary, we are led to consider matter as something not only naturally quiescent and inert, but sluggish, averse from motion, and prone to rest (we must be pardoned this metaphorical language, because we can find no other term). What is expressed by it, on this occasion, is precisely one of the erroneous or inadequate conceptions that are suggested to our thoughts by reason of the poverty of language. We animate matter in order to give it motion, and then we endow it with a sort of moral character in order to explain the appearance of those motions.

26. But more extended observation has made men gradually desert their first opinions, and at last allow that matter has no peculiar aptitude to rest. All the retardations that we *observe* have been discovered, one after another, to have a distinct reference to some external circumstances. The diminution of motion is always observed to be accompanied by the removal of obstacles, as when a ball moves through sand, or water, or air; or it is owing to opposite motions which are destroyed; to roughness of the path, or to friction, &c. We find that the more we can keep these things out of the way, the less are the motions diminished. A pendulum will vibrate but a short while in water; much longer in air; and in the exhausted receiver it will vibrate a whole day. We know that we cannot remove *all* obstacles; but we are led by such observations to conclude that, if they *could be completely removed*, our motions would continue for ever. And this conclusion is almost demonstrated by the motions of the heavenly bodies, to which we know of no obstacles, and which we really observe to retain their motions for many thousand years, without the smallest sensible diminution.

Inactivity of matter denied by Leibnitz.

27. Another set of philosophers maintain an opinion directly opposite to that of the inactivity of matter, and assert, that it is essentially active, and continually changing its state. Faint traces of this are to be found in the writings of Plato, Aristotle, and their commentators. Mr Leibnitz is the person who has treated this question most systematically and fully. He supposes every particle of matter to have a principle of individuality, which he therefore calls a *Monad*. This monad has a sort of *perception* of its situation in the universe, and of its relation to every other part of this universe. Lastly, he says that the monad acts on the material particle much in the same way that the soul of man acts on his body. It modifies the motion of the material atom (in conformity, however, to unalterable laws), producing all those modifications of motion that we observe. Matter, therefore, or at least particles of matter, are continually active, and continually changing their situation.

Monads, what.

This opinion ill founded.

It is quite unnecessary to enter on a formal confutation of Mr Leibnitz's system of monads, which differs very little from the system of elemental minds, and is equally whimsical and frivolous; because it only makes the unlearned reader stare, without giving him any information. Should it even be granted, it would not, any more than the action of animals, invalidate the general proposition which we are endeavouring to establish as the fundamental law of motion. Those powers of the monads, or of the elemental minds, are the causes of all the changes of motion; but the mere material particle is subject to the law, and requires the exertion of the monad in order to exhibit a change of motion.

28. A third sect of philosophers, at the head of which we may place Sir Isaac Newton, maintain the doctrine enounced in the proposition. But they differ much in respect of the foundation on which it is built.

Some philosophers deduce this law of motion from the want of a determining cause.

Some assert that this truth flows from the nature of the thing. If a body be at rest, and you assert that it will not remain at rest, it must move in some one direction. If it be in motion in any direction, and with any velocity, and do not continue its equable, rectilineal motion, it must either be accelerated or retarded; it must turn either to one side or to some other side. The event, whatever it be, is individual and determinate; but no cause which

First Law of Motion.

can determine it is supposed; therefore the determination cannot take place, and no change will happen in the condition of the body with respect to motion. It will continue at rest, or persevere in its rectilineal and equable motion.

But considerable objections may be made to this argument of *sufficient reason*, as it is called. In the immensity and perfect uniformity of space and time, there is no determining cause why the visible universe should exist in the place in which we see it rather than in another, or at this time rather than at another. Nay, the argument seems to beg the question. A cause of determination is required as essentially necessary—a determination may be without a cause, as well as a motion without a cause.

Others deduce it from experience.

29. Other philosophers, who maintain this doctrine, consider it merely as an experimental truth; and proofs of its universality are innumerable.

When a stone is thrown from the hand, we press it forward while in the hand, and let it go when the hand has acquired the greatest rapidity of motion that we can give it. The stone continues in that state of motion which it acquired gradually along with the hand. We can throw a stone much farther by means of a sling, because, by a very moderate motion of the hand, we can whirl the stone round till it acquire a very great velocity, and then we let go one of the strings, and the stone escapes, *by continuing* its rapid motion. We see it still more distinctly in shooting an arrow from a bow. The string presses hard on the notch of the arrow, and it yields to this pressure and goes forward. The string alone would go faster forward. It therefore *continues* to press the arrow forward, and accelerates its motion. This goes on till the bow is as much unbent as the string will allow. But the string is now a straight line. It came into this position with an accelerated motion, and it therefore goes a little beyond this position, but with a retarded motion, being checked by the bow. But there is nothing to check the arrow, therefore the arrow quits the string and flies away.

These are simple cases of perseverance in a state of motion, where the procedure of nature is so easily traced that we perceive it almost intuitively. It is no less clear in other phenomena which are more complicated; but it requires a little reflection to trace the process. We have often seen an equestrian showman ride a horse at a gallop, standing on the saddle, and stepping from it to the back of another horse that gallops alongside at the same rate; and he does this seemingly with as much ease as if the horses were standing still. The man has the same velocity with the horse that gallops under him, and keeps this velocity while he steps to the back of the other. If that other were standing still, the man would fly over his head. And if a man should step from the back of a horse that is standing still, to the back of another that gallops past him, he would be left behind. In the same manner, a slack-wire dancer tosses oranges from hand to hand while the wire is in full swing. The orange, swinging along with the hand, retains the velocity; and when in the air, follows the hand, and falls into it when it is in the opposite extremity of its swing. A ball dropped from the mast-head of a ship that is sailing briskly forward, falls at the foot of the mast. It retains the motion which it had while in the hand of the person who dropped it, and follows the mast during the whole of its fall.

We also have familiar instances of the perseverance of a body in a state of rest. When a vessel filled with water is drawn suddenly along the floor, the water dashes over the posterior side of the vessel. It is left behind. In the same manner, when a coach or boat is dragged forward, the persons in it find themselves strike against the hinder part of the carriage or boat. Properly speaking, it is the carriage that strikes on them. In like manner, if we lay a card on the tip of the finger, and a piece of money on the card, we may nick away the card, by hitting it neatly on its edge; but the piece of money will be left behind, lying on the tip of the finger. A ball will go through a wall and fly onward; but the wall is left behind. Buildings are thrown down by earthquakes; sometimes by being tossed from their foundations, but more generally by the ground on which they stand being hastily drawn sidewise from under them, &c.

Common experience insufficient.

30. But common experience seems insufficient for establishing this fundamental proposition of mechanical philosophy. We must, on the faith of the Copernican system, grant that we never saw a body at rest, or in uniform rectilineal motion; yet this seems absolutely necessary before we can say that we have established this proposition experimentally.

What we imagine, in our experiments, to be putting a body, formerly at rest, into motion, is, in fact, only changing a most rapid motion, not less, and probably much greater, than 90,000 feet per second. Suppose a cannon pointed east, and the bullet discharged at noon day with sixty times greater velocity than we have ever been able to give it: it would appear to set out with this unmeasurable velocity to the eastward, to be gradually retarded by the resistance of the air, and at last brought to rest by hitting the ground. But, by reason of the earth's motion round the sun, the fact is quite the reverse. Immediately before the discharge, the ball was moving to the westward with the velocity of 90,000 feet per second nearly. By the explosion of the powder, and its pressure on the ball, some of this motion is destroyed, and at the muzzle of the gun the ball is moving slower, and the cannon is hurried away from it to the westward. The air, which is also moving to the westward 90,000 feet in a second, gradually communicates motion to the ball, in the same manner as a hurricane would do. At last (the ball dropping all the while) some part of the ground hits the ball, and carries it along with it.

Other observations must therefore be resorted to, in order to obtain an experimental proof of this proposition; and such are to be found. Although we cannot measure the absolute motions of bodies, we can observe and measure accurately their relative motions, which are the differences of their absolute motions. Now, if we can show experimentally that bodies show equal tendencies to resist the augmentation and the diminution of their relative motions, they, *ipso facto*, show equal tendencies to resist the augmentation or diminution of their absolute motions. Therefore let two bodies, A and B, be put into such a situation that they cannot (by reason of their impenetrability, or the action of their mutual powers) persevere in their relative motions. The change produced on A is the effect and the measure of B's tendency to persevere in its former state; and therefore the proportion of these changes will show the proportion of their tendencies to maintain their former states. Therefore let the following experiment be made at noon.

Experiments proper for the purpose.

Let A, apparently moving westward three feet per second, hit the equal body B apparently at rest. Suppose, 1*st*, that A impels B forward without any diminution of its own velocity. This result would show that B manifests no tendency to maintain its motion unchanged, but that A retains its motion undiminished.

2*dly*, Suppose that A stops, and that B remains at rest. This would show that A does not resist a diminution of motion, but that B retains its motion unaugmented.

3*dly*, Suppose that both move westward with the velocity of one foot per second. The change on A is a diminution of velocity, amounting to two feet per second.

First Law of Motion.

This is the effect and the measure of B's tendency to maintain its velocity unaugmented. The change on B is an augmentation of one foot per second made on its velocity; and this is the measure of A's tendency to maintain its velocity undiminished. This tendency is but half of the former; and this result would show that the resistance to a diminution of velocity is but half of the resistance to augmentation. It is perhaps but one quarter, for the change on B has produced a double change on A.

4thly, Suppose that both move westward at the rate of one and a half foot per second. It is evident that their tendencies to maintain their states unchanged are now equal.

5thly, Suppose A = 2 B, and that both move, after the collision, two feet per second; B has received an addition of two feet per second to its former velocity. This is the effect and the measure of A's whole tendency to retain its motion undiminished. Half of this change on B measures the persevering tendency of the half of A; but A, which formerly moved with the apparent or relative velocity three, now moves (by the supposition) with the velocity two, having lost a velocity of one foot per second. Each half of A therefore has lost this velocity, and the whole loss of motion is two. Now this is the measure of B's tendency to maintain its former state unaugmented; and this is the same with the measure of A's tendency to maintain its own former state undiminished. The conclusion from such a result would therefore be, that bodies have equal tendencies to maintain their former states of motion without augmentation and without diminution.

What is supposed in the fourth and fifth cases is really the result of all the experiments which have been tried; and this law regulates all the changes of motion which are produced by the mutual actions of bodies in impulsions. This assertion is true without exception or qualification. Therefore it appears that bodies have no preferable tendency to rest, and that no fact can be adduced which should make us suppose that a motion once begun should suffer any diminution without the action of a changing cause.

But experience is not the proper foundation of an axiom.

But we must now observe, that this way of establishing the first law of motion is very imperfect, and altogether unfit for rendering it the fundamental principle of a whole and extensive science. It is subject to all the inaccuracy that is to be found in our best experiments; and it cannot be applied to cases where scrupulous accuracy is wanted, and where no experiment can be made.

Let us therefore examine the proposition by means of principles which contain the foundation of all our knowledge of active nature. These will, we imagine, give a decision of this question that is speedy and accurate; showing the proposition to be an axiom or intuitive consequence of the relations of those ideas which we have of motion, and of the causes of its production and changes.

Logical proof.

31. It has been fully demonstrated that the powers or forces of which we speak so much are never the immediate objects of our perception. Their very existence, their kind, and their degree, are instinctive inferences from the motions which we observe and class. It evidently follows from this experimental and universal truth, 1*st*, that where no change of motion is observed, no such inference is made, that is, no power is *supposed* to act. But whenever any change of motion is observed, the inference is made; that is, a power or force is supposed to have acted.

In the same form of logical conclusion, we must say that, 2*dly*, when no change of motion is *supposed* or thought of, no force is *supposed;* and that whenever we *suppose* a change of motion, we in fact, though not in terms, suppose a changing force. And, on the other hand, whenever we suppose the action of a changing force, we suppose the change of motion; for the action of this force, and the change of motion, is one and the same thing. We cannot think of the action without thinking of the indication of that action; that is, the change of motion. In the same manner, when we do not think of a changing force, or suppose that there is no action of a changing force, we in fact, though not in terms, suppose that there is no indication of this changing force; that is, that there is no change.

It is a law of human thought,

Whenever, therefore, we suppose that no mechanical force is acting on a body, we in fact suppose that the body continues in its former condition with respect to motion. If we suppose that nothing accelerates, or retards, or deflects the motion, we suppose that it is not accelerated, nor retarded, nor deflected. Hence follows the proposition in express terms—*We suppose that the body continues in its former state of rest or motion, unless we suppose that it is changed by some mechanical force.*

Thus it appears that this proposition is not a matter of experience or contingency, depending on the properties which it has pleased the Author of nature to bestow on body; it is to us a necessary truth. The proposition does not so much express any thing with regard to body, as it does the operations of our mind when contemplating body. It may perhaps be essential to body to move in some particular direction. It may be essential to body to stop as soon as the moving cause has ceased to act; or it may be essential to body to diminish its motion gradually, and finally come to rest. But this will not invalidate the truth of this proposition. These circumstances in the nature of body, which render those modifications of motion essentially necessary, are the causes of those modifications and in our study of nature they will be considered by us as changing forces, and will be known and called by that name. And if we should ever see a particle of matter in such a situation that it is affected by those essential properties alone, we shall, from observation of its motion, discover what those essential properties are.

and almost an identical proposition.

This law turns out at last to be little more than a tautological proposition; but mechanical philosophy, as we have defined it, requires no other sense of it; for even if we should suppose that body, of its own nature, is capable of changing its state, this change must be performed according to some law which characterizes the nature of body; and the knowledge of the law can be had in no other way than by observing the deviations from uniform rectilineal motion. It is therefore indifferent whether those changes are derived from the nature of the thing or from external causes; for, in order to consider the various motions of bodies, we must first consider this nature of matter as a mechanical affection of matter, operating in every instance; and thus we are brought back to the law enounced in this proposition. This becomes more certain when we reflect that the external causes (such as gravity or magnetism), which are acknowledged to operate changes of motion, are equally unknown to us with this essential original property of matter, and are, like it, nothing but inferences from the phenomena.

The above very diffuse discussions may appear superfluous to many readers, and even cumbersome; but we trust that the philosophical reader will excuse our anxiety on this head, when he reflects on the complicated, indistinct, and inaccurate notions commonly had of the subject. We may include Sir Isaac Newton in the number of those who have at least introduced modes of expression which mislead the minds of incautious persons, and suggest inadequate notions, incompatible with the pure doctrine of the proposition. Although in words they disclaim the doctrine that rest is the natural state of body, and that force is necessary for the continuation of its motion,

First Law of Motion.

yet in words they (and most of them in thought) likewise abet that doctrine: for they say that there resides in a moving body a *power* or *force*, by which it perseveres in its motion. They call it the *vis insita*, the *inherent force, of a moving body.* This is surely giving up the question: for if the motion is supposed to be continued in consequence of a force, that force is *supposed* to be exerted; and it is supposed that if it were not exerted, the motion would cease; and therefore the proposition must be false. Indeed it is sometimes expressed so as seemingly to ward off this objection. It is said that the body continues in uniform rectilineal motion, unless affected by some *external cause.* But this way of speaking obliges us, at first setting out in natural philosophy, to assert that gravity, magnetism, electricity, and a thousand other mechanical powers, are external to the matter which they put in motion. This is quite improper. It is the business of philosophy to discover whether they be external or not; and if we assert that they are, we have no principles of argumentation with those who deny it. It is this one thing that has filled the study of nature with all the jargon of ethers, and other invisible, intangible fluids, which has disgraced philosophy, and greatly retarded its progress.

Vis insita, inherent force, are improper terms in their usual acceptation.

32. We must observe, that the terms *vis insita*, inherent force, are very improper. There is no dispute among philosophers in calling every thing a force that produces a change of motion, and in inferring the action of such a force whenever we observe a change of motion. It is surely incongruous to give the same name to what has not this quality of producing a change, or to infer (or rather to suppose) the energy of a force when no change of motion is observed. This is one among many instances of the danger of mistake when we indulge in analogical discussions. All our language, at least, on this subject is analogous. I feel that in order to oppose animal force I must exert force. But I must exert force in order to oppose a body in motion; therefore I imagine that the moving body possesses force. A bent spring will drive a body forward by unbending; therefore I say that the spring exerts force. A moving body impels the body which it hits; therefore I say that the impelling body possesses and exerts force. I imagine farther, that it possesses force only by being in motion, or because it is in motion; because I do not find that a quiescent body will put another into motion by touching it. But we shall soon find this to be false in many, if not in all cases, and that the communication of motion depends on the mere vicinity, and not on the motion of the impelling body; yet we ascribe the exertion of the *vis insita* to the circumstance of the continued motion. We therefore conceive the force as arising from or as consisting in the impelling body's being in motion; and, with a very obscure and indistinct conception of the whole matter, we call it *the force by which the body preserves itself in motion.* Thus, taking it for granted that a force resides in the body, and being obliged to give it some office, this is the only one that we can think of.

33. But philosophers imagine that they perceive the necessity of the exertion of a force in order to the continuation of a motion. Motion (say they) is a continued action; the body is every instant in a new situation; there is the continual production of an effect, therefore the continual action of a cause.

Motion is not the continual production of an effect.

This, however, is a very inaccurate way of thinking. We have a distinct conception of motion; and we conceive that there is such a thing as a moving cause, which we distinguish from all other causes by the name *force.* It produces motion. If it does this, it produces the character of motion, which is a continual change of place. Motion is not action, but the effect of an action; and this action is as complete in the instant immediately succeeding the beginning of the motion as it is a minute after. The subsequent change of place is the continuation of an effect already produced. The *immediate* effect of the moving force is a *determination*, by which, if not hindered, the body would go on for ever from place to place. It is in this determination only that the state or condition of the body can differ from a state of rest; for in any instant the body does not describe any space, but has a determination by which it will describe a certain space uniformly in a certain time. Motion is a condition, a state, or mode of existence, and no more requires the continued agency of the moving cause than yellowness or roundness does. It requires some chemical agency to change the yellowness to greenness; and it requires a mechanical cause or a force to change this motion into rest. When we see a moving body stop short in an instant, or be gradually but quickly brought to rest, we never fail to speculate about a cause of this cessation or retardation. The case is no way different in itself although the retardation should be extremely slow. We should always attribute it to a cause. It requires a cause to put a body out of motion, as much as to put it into motion. This cause, if not external, must be found in the body itself; and it must have a self-determining power, and may as well be able to put itself into motion as out of it.

If this reasoning be not admitted, we do not see how any effect can be produced by any cause. Every effect supposes something *done;* and any thing done implies that the thing done may remain till it be *undone* by some other cause. Without this it would have no existence. If a moving cause did not produce continued motion by its instantaneous action, it could not produce it by any continuance of that action; because in no instant of that action does it produce continued motion.

We must therefore give up the opinion, that there resides in a moving body a force *by which it is kept in motion;* and we must find some other way of explaining that remarkable difference between a moving body and a body at rest, by which the first causes other bodies to move by hitting them, while the other does not do this by merely touching them. We shall see, with the clearest evidence, that motion is necessary in the impelling body, in order that it may permit the forces inherent in one or both bodies to continue this pressure long enough for producing a sensible or considerable motion. But these moving forces are inherent in bodies, whether they are in motion or at rest.

Communication of motion is an improper phrase;

34. The foregoing observations show us the impropriety of the phrase *communication of motion.* By thus reflecting on the notions that are involved in the general conception of one body being made to move by the impulse of another, we perceive that there is nothing individual transferred from the one body to the other. The determination to motion, indeed, existed only in the impelling body before collision; whereas, afterwards, both bodies are so conditioned or determined. But we can form no notion of the thing transferred. With the same metaphysical impropriety we speak of the communication of joy, of fever.

so is vis inertiæ.

35. Kepler introduced a term *inertia, vis inertiæ,* into mechanical philosophy; and it is now in constant use. But writers are very careless and vague in the notions which they affix to these terms. Kepler and Newton seem generally to employ it for expressing the fact, the perseverance of the body in its present state of motion or rest: but they also frequently express by it something like an indifference to motion or rest, *manifested by its requiring the same quantity of force to make an augmentation of its motion as to make an equal diminution of it.* The popular notion is

First Law of Motion.

like that which we have of actual resistance; and it always implies the notion of force *exerted* by the resisting body. We suppose this to be the exertion of the *vis insita*, or the *inherent force* of a body in motion. But we have the same notion of resistance from a body at rest which we set in motion. Now surely it is in direct contradiction to the common use of the word *force*, when we suppose resistance from a body at rest; yet *vis inertiæ* is a very common expression. Nor is it more absurd (and it is very absurd) to say, that a body maintains its state of rest by the exertion of a *vis inertiæ*, than to say that it maintains its state of motion by the exertion of an *inherent force.* We should avoid all such metaphorical expressions as *resistance, indifference, sluggishness*, or *proneness to rest* (which some express by *inertia*) because they seldom fail to make us indulge in metaphorical notions, and thus lead us to misconceive the *modus operandi*, or procedure of nature.

There is *no resistance whatever observed* in these phenomena, for the force employed always produces its *complete* effect. When I throw down a man, and find that I have employed no more force than was sufficient to throw down a similar and equal mass of dead matter, I know by this that he *has not* resisted; but I conclude that he *has* resisted if I have been obliged to employ much more force. There is therefore no resistance, properly so called, when the exerted force is observed to produce its full effect. To say that there *is* resistance, is therefore a real misconception of the way in which mechanical forces have operated in the collision of bodies. There is no more resistance in these cases than in any other natural changes of condition. We are guilty, however, of the same impropriety of language in other cases, where the cause of it is more evident. We say that colours in grain *resist* the action of soap and of the sun, but that Prussian blue does not. We all perceive that in this expression the word resistance is entirely figurative; and we should say that Prussian blue *resists* soap, if we are right in saying that a body resists any force employed to change its state of motion; for soap must be employed to discharge or change the colour, *and it does change it.* Force must be employed to change a motion, *and it does change it.* The impropriety, both of thought and language, is *plain* in the one case, and it is no less *real* in the other. Both of the terms *inherent force* and *inertia* may be used with safety for abbreviating language, if we be careful to employ them only for expressing *either the simple fact of persevering in the former state*, or *the necessity of employing a certain determinate force in order to change that state, and if we avoid all thought of resistance.*

Deviations from uniform rectilineal motion are the only indications of force.

36. From the whole of this discussion we learn that the deviations from uniform motions are the indications of the existence and agency of mechanical forces, and that they are the only indications. The indication is very simple—mere change of place; it can therefore indicate nothing but what is very simple, the something competent to the production of the very motion that we observe; and when two changes of motion are precisely similar, they indicate the same thing. Suppose a mariner's compass on the table, and that by a small tap with my finger I cause the needle to turn off from its quiescent position ten degrees. I can do the same thing by bringing a magnet near it, or by bringing an electrified body near it, or by the unbending of a fine spring pressing it aside, or by a puff of wind, or by several other methods. In all these cases the indication is the same; therefore the thing indicated is the same, namely, a certain intensity and direction of a moving power. How it operates, or in what manner it exists and exerts itself in these instances, outwardly so different, is not under consideration at present. Impulsiveness, intensity, and direction, are all the circumstances of resemblance by which the affections of matter are to be characterized; and it is to the discovery and determination of these alone that our attention is now to be directed. We are directed in this research by the

Second Law of Motion.

SECOND LAW OF MOTION.

Every change of motion is proportional to the force impressed, and is made in the direction of that force.

37. This law also may almost be considered as an identical proposition; for it is equivalent to saying that the changing force is to be measured by the change which it produces, and that the direction of this force is the direction of the change. Of this there can be no doubt, when we consider the force in no other sense than that of the cause of motion, paying no attention to the form or manner of its exertion. Thus, when a pellet of tow is shot from a pop-gun by the expansion of the air compressed by the rammer, or where it is shot from a toy pistol by the unbending of the coiled wire, or when it is nicked away by the thumb like a marble—if, in all these cases, it moves off in the same direction, and with the same velocity, we cannot consider or think of the force, or at least of its exertion, as any how different. Nay, when it is driven forward by the instantaneous percussion of a smart stroke, although the manner of producing this effect (if possible) is essentially different from what is conceived in the other cases, we must still think that the propelling force, considered as a propelling force, is one and the same. In short, this law of motion, as thus expressed by Sir Isaac Newton, is equivalent to saying, " that we take the changes of motion as the measures of the changing forces, and the direction of the change for the indication of the direction of the forces:" for no reflecting person can pretend to say that it is a deduction from the acknowledged principle, that effects are proportional to their causes. We do not affirm this law from having observed the proportion of the forces and the proportion of the changes, and that these proportions are the same; and from having observed that this has obtained through the whole extent of our study of nature. This would indeed establish it as a physical law, an universal fact; and it is, in fact, so established. But this does not establish it as a law of motion, according to our definition of that term; as a law of human thought, the result of the relations of our ideas, as an intuitive truth. The injudicious attempts of philosophers to prove it as a matter of observation, have occasioned the only dispute that has arisen in mechanical philosophy. It is well known that a bullet moving with double velocity penetrates four times as far. Many other similar facts corroborate this: and the philosophers observe, that four times the force has been expended to generate this double velocity in the bullet; it requires four times as much powder. In all the examples of this kind it would seem that the ratio of the forces employed has been very accurately ascertained; yet this is the invariable result. Philosophers, therefore, have concluded that moving forces are not proportional to the velocities which they produce, but to the squares of those velocities. It is a strong confirmation to see that the bodies in motion seem to possess forces in this very proportion, and produce effects in this proportion; penetrating four times as deep when the velocity is only twice as great, &c.

But if this be a just estimation, we cannot reconcile it to the concession of the same philosophers, who grant that the velocity is proportional to the force impressed, in the cases where we have no previous observation of the ratio of the forces, and of its equality to the ratio of the velocities. This is the case with gravity, which these

Second Law of Motion.

philosophers always measure by its accelerating power, or the velocity which it generates in a given time. And this cannot be refused by them; for cases occur where the force can be measured in the most natural manner by the actual pressure which it exerts. Gravity is thus measured by the pressure which a stone exerts on its supports. A weight which at Quito will pull out the rod of a spring steelyard to the mark 312, will pull it to 313 at Spitzbergen; and it is a fact, that a body will fall 313 inches at Spitzbergen in the same time that it falls 312 at Quito. Gravitation is the cause both of the pressure and the fall, and it is a matter of unexcepted observation that they have always the same ratio. The philosophers who have so strenuously maintained the other measure of forces are among the most eminent of those who have examined the motions produced by gravity, magnetism, electricity, &c.; and they never think of measuring those forces any other way than by the velocity. It is in this way that the whole of the celestial phenomena are explained in perfect uniformity with observation, and that the Newtonian philosophy is considered as a demonstrative science.

There must, therefore, be some defect in the principle on which the other measurement of forces is built, or in the method of applying it. Pressure is undoubtedly the immediate and natural measure of force; yet we know that four springs, or a bow four times as strong, give only a double velocity to an arrow.

The truth of our law rests on this only, that we assume the changes of motion as the measure of the changing forces, or at least as the measures of their exertions in producing motion. In fact, they are the measures only of a certain circumstance, in which the actions of very different natural powers may resemble each other, namely, the competency to produce motion. They do not, perhaps, measure their competency to produce heat, or even to bend springs. We can surely consider this apart from all other circumstances, and it is worthy of separate consideration. Let us see what can be, and what ought to be, deduced from this way of treating the subject.

Change of motion is itself a motion.

38. The motion of a body may certainly remain unchanged. If the direction and velocity remain the same, we perceive no circumstance in which its condition with respect to motion differs. Its change of place or situation can make no difference; for this is implied in the very circumstance of the bodies being in motion.

But if either the velocity or direction change, then surely is its mechanical condition no longer the same; a force has acted on it, either intrinsic or from without, either accelerating, or retarding, or deflecting it. Supposing the direction to remain the same, its difference of condition can consist in nothing but its difference of velocity. This is the only circumstance in which its condition can differ, as it passes through two different points of its rectilineal path. It is this determination by which the body will describe a certain determinate space uniformly in a given time, which defines its condition as a moving body; the changes of this determination are the measures of their own causes, and to those causes we have given the name *force*. Those causes may reside in other bodies, which may have other properties, characterized and measured by other effects. Pressure may be one of those properties, and may have its own measures; these may or may not have the same proportion with that property which is the cause of a change of velocity; and therefore changes of velocity may not be a measure of pressure. This is a question of fact, and requires observation and experience; but, in the mean time, velocity, and the change of velocity, is the measure of moving force and of changing force. When, therefore, the change of velocity is the same whatever the previous velocity may be, the changing force must be considered as the same. Therefore, finally, if the previous velocity is nothing, and consequently the change on that body is the very velocity or motion that it acquires, we must say, that the force which produces a certain change in the velocity of a moving body is the same with the force which would impart to a body at rest a velocity equal to this change or difference of velocity produced on the body already in motion.

39. This manner of estimating force is in perfect conformity to our most familiar notions on these subjects. We conceive the weight or downward pressure of a body as the cause of its motion downwards; and we conceive it as belonging to the body at all times, and in all places, whether falling, or rising upwards, or describing a parabola, or lying on a table; and, accordingly, we observe, that in every state of motion it receives equal changes of velocity in the same or an equal time, and all in the direction of its pressure.

40. All that we have now said of a change of velocity might be repeated of a change of direction. It is surely possible that the same change of direction may be made on any two motions. Let one of the motions be considered as growing continually slower, and terminating in rest. In every instant of this motion it is possible to make one and the same change on it. The same change may therefore be made at the very instant that the motion is at an end. In this case the change is the very motion which the body acquires from the changing force. Therefore, in this case also, we must say that a change of motion is itself a motion, and that it is the motion which the force would produce in a body that was previously at rest.

How ascertained and measured.

41. The result of these observations is evidently this, that we must ascertain, in every instance, what is the change of motion, and mark it by characters that are conspicuous and distinguishing; and this mark and measure of change must be a motion. Then we must say, that the changing force is that which would produce this motion in a body previously at rest. We must see how this is manifest as a motion in the difference between the former motion and the new motion; and, on the other hand, we must see how the motion produceable in a quiescent body may be so combined with a motion already existing as to exhibit a new motion, in which the agency of the changing force may appear.

Suppose a ship at anchor in a stream, while one man walks forward on the quarter deck at the rate of two miles per hour, another walks from stem to stern at the same rate, a third walks athwart ship, and a fourth stands still. Let the ship be supposed to cut or part her cable, and float down the stream at the rate of three miles per hour. We cannot conceive any difference in the change made on each man's motion in absolute space; but their motions are now exceedingly different from what they were: the first man, whom we may suppose to have been walking westward, is now moving eastward one mile per hour; the second is moving eastward four miles per hour, and the third is moving in an oblique direction, about three points north or south of due east. All have suffered the same change of condition with the man who had been standing still. He has now got a motion eastward three miles per hour. In this instance, we see very well the circumstance of sameness that obtains in the change of these four conditions. It is the motion of the ship which is blended with the other motions. But this circumstance is equally present whenever the same previous motions are changed into the same new motions. We must learn to expiscate this; which we shall do by considering the manner in which the motion of the ship is blended with each of the men's motions.

Second Law of Motion.

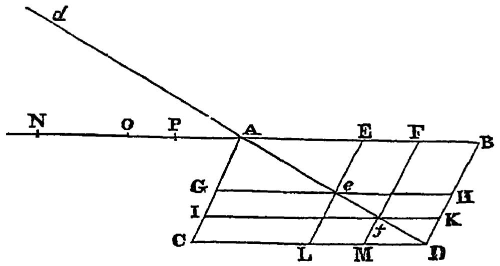
Composition of motion.

42. This kind of combination has been called the *composition of motion;* because, in every point of the motion really pursued, the two motions are to be found.

The fundamental theorem on this subject is this: Two uniform motions in the sides of a parallelogram compose an uniform motion in the diagonal.

Suppose that a point A (fig. 1) describes AB uniformly in some given time, while the line AB is carried uniformly along AC in the same time, keeping always parallel to its first position AB. The point A, by the combination of these motions, will describe AD, the diagonal of the parallelogram ABDC, uniformly in the same time.

Fig. 1.



For it is plain that the velocities in AB and AC are proportional to AB and AC, because they are uniformly described in the same time. When the point has got to E, the middle of AB, the line AB has got into the situation GH, half way between AB and CD, and the point E is in the place *e*, the middle of GH. Draw E*e*L parallel to AC. It is plain that the parallelograms ABDC and AE*e*G are similar; because AE and AG are the halves of AB and AC, and the angle at A is common to both. Therefore, by a proposition in the elements, they are about the same diagonal, and the point *e* is in the diagonal of AD. In like manner, it may be shown, that when A has described AF, three fourths of AB, the line AB will be in the situation IK; so that AI is three fourths of AC, and the point *f*, in which A is now found, is in the diagonal AD. It will be the same in whatever point of AB the describing point A be supposed to be found. The line AB will be on a similar point of AC, and the describing point will be in the diagonal AD.

Moreover, the motion in AD is uniform; for A*e* is described in the time of describing AE; that is, in half the time of describing AB, or in half the time of describing AD. In like manner, A*f* is described in three fourths of the time of describing AD, &c. &c.

Lastly, the velocity in the diagonal AD is to the velocity in either of the sides as AD is to that side. This is evident, because they are uniformly described in the same time.

This is justly called *a composition of the motions* AB *and* AC, as will appear by considering it in the following manner: Let the lines AB, AC be conceived as two material lines like wires. Let AB move uniformly from the situation AB into the situation CD, while AC moves uniformly into the situation BD. It is plain that their intersection will always be found on AD. The point *e*, for example, is a point common to both lines. Considered as a point of EL, it is then moving in the direction *e*H or AB; and considered as a point of GH, it is moving in the direction *e*L. Both of these motions are therefore blended in the motion of the intersection along AD. We can conceive a small ring at *e* embracing loosely both of the wires. This material ring will move in the diagonal, and *will really partake* of both motions.

Thus we see how the motion of the ship is actually blended with the motions of the three men; and the circumstance of sameness which is to be found in the four changes of motion is this motion of the ship, or of the man who was standing still. By composition with each of the three former motions, it produces each of the three new motions. Now, when each of two primitive motions is the same, and each of the new motions is the same, the change is surely the same. If one of the changes has been brought about by the actual composition of motions, we know precisely what that change is; and this informs us what the other is, in whatever way it was produced.

Hence we infer that,

Its mark and measure.

43. *When a motion is any how changed, the change is that motion which, when compounded with the former motion, will produce the new motion.* Now, because we assume the change as the measure and characteristic of the changing force, we must do so in the present instance; and we must say,

Changing force.

44. *That the changing force is that which will produce in a quiescent body the motion which, by composition with the former motion of a body, will produce the new motion.*

And, on the other hand,

Its effect.

When the motion of a body is changed by the action of any force, the new motion is that which is compounded of the former motion, and of the motion which the force would produce in a quiescent body.

Deflecting force.

When a force changes the direction of a motion, we see that its direction is transverse in some angle BAC; because a diagonal AD always supposes two sides. As we have distinguished any change of direction by the term *deflection*, we may call the transverse force a *deflecting force.*

In this way of estimating a change of motion, all the characters of both motions are preserved, and it expresses every circumstance of the change; the mere change of direction, or the angle BAD, is not enough, because the same force will make different angles of deflection, according to the velocity of the former motion, or according to its direction. But in this estimation the full effect of the deflecting force is seen; it is seen *as a motion;* for when half of the time is elapsed, the body is at *e* instead of E; when three fourths are elapsed it is at *f* instead of F; and at the end of the time it is at D instead of B. In short, the body has moved uniformly away from the points at which it would have arrived independent of the change; and this motion has been in the same direction, and at the same rate, as if it had moved from A to C by the changing force alone. Each force has produced its full effect; for when the body is at D, it is as far from AC as if the force AC had not acted on it; and it is as far from AB as it would have been by the action of AC alone.

For all these reasons, therefore, it is evident, that if we are to abide by our measure and character of force as a mere producer of motion, we have selected the proper characteristic and measure of a changing force; and our descriptions, in conformity to this selection, must be agreeable to the phenomena of nature, and retain the accuracy of geometrical procedure; because, on the other hand, the results which we deduce from the supposed influence of those forces are formed in the same mould. It is not even requisite that the real exertions of the natural forces, such as pressure of various kinds, &c. shall follow these rules; for their deviations will be considered as new forces, although they are only indications of the differences of the real forces from our hypothesis. We have obtained the precious advantage of mathematical investigation, by which we can examine the law of exertion which characterizes every force in nature.

45. On these principles we establish the following fundamental elementary proposition, of continual and indispensable use in all mechanical inquiries.

Second Law of Motion.

Fundamental theorem.

If a body or material particle be subjected at the same time to the action of two moving forces, each of which would separately cause it to describe the side of a parallelogram uniformly in a given time, the body will describe the diagonal uniformly in the same time.

For the body, whose motion AB was changed into AD, had gotten its motion by the action of some force. It was moving along NAB, and when it reached the point A, the force AC acted on it. The primitive motion is the same, or the body is in the same condition in every instant of the primitive motion. It may have acquired this motion when it was in N, or when at O, or any other point of NA. In all these cases, if AC act on it when it is in A, it will always describe AD; therefore it will describe AD when it acquires the primitive motion also in A; that is, if the two forces act on it at one and the same instant. The demonstration may be neatly expressed thus: The change induced by each force on the motion produced by the other is the motion which it would produce in the body if previously at rest. Therefore the motion resulting from joint action is the motion which is compounded of these two motions, or it is a motion in the diagonal of the parallelogram, of which these motions are the sides.

Composition of forces.

This is called the *composition of forces.* The forces which produce the motions along the sides of the parallelogram are called the *simple forces*, or the *constituent forces;* and the force which would alone produce the motion along the diagonal is called the *compound force*, the *resulting force*, the *equivalent force.*

46. On the other hand, the force which produces a motion along any line whatever may be conceived as resulting from the combined action of two or more forces. We may *know* or *observe* it to be so; as when we see a lighter dragged along a canal by two horses, one on each side. Each pulls the boat directly toward himself in the direction of the track-rope; the boat cannot go both ways, and its real motion, whatever it is, results from this combined action. This might be produced by a single force; for example, if the lighter be dragged along the canal by a rope from another lighter which precedes it, being dragged by one horse, aided by the helm of the foremost lighter. Here the real force is not the resulting, or the compound, but the equivalent force.

Resolution of forces.

This view of a motion mechanically produced is called the *resolution of forces.* The force in the diagonal is said to be *resolved* into the two forces, having the directions and velocities represented by the sides. This practice is of the most extensive and multifarious use in all mechanical disquisitions. It may frequently be exceedingly difficult to manage the complication of the many real forces which concur in producing a phenomenon; and by substituting others, whose combined effects are equivalent, our investigation may be much expedited. But more of this afterwards.

We must carefully remember, that when the motion AD is once begun, all composition is at an end, and the motion is a simple motion. The two determinations, by one of which the body would describe AB, and by the other of which it would describe AC, no longer *co-exist* in the body. This was the case only *in the instant*, in the very act of changing the motion AB into the motion BD; yet is the motion AD equivalent to a motion which is produced by the *actual composition* of two motions AB and AC; in which case the two motions co-exist in every point of AD.

Usual demonstration inconclusive.

47. Accordingly this is the way in which the composition of forces is usually illustrated, and thought to be demonstrated. A man is supposed (for instance) to walk uniformly from A to C on a sheet of ice, while the ice is carried uniformly along AB by the stream. The man's real motion is undoubtedly along AD; but this is by no means a demonstration that the instantaneous or short-lived action of two forces would produce that motion; the man must continue to exert force in order to walk; and the ice is dragged along by the stream. Some indeed express this proof in another way, saying, let a body describe AB, while the space in which this motion is performed is carried along AC. The ice may be carried along, and may, by friction or otherwise, drag the man along with it; but a space cannot be removed from one place to another, nor, if it could, would it take the man with it. Should a ship start suddenly forward while a man is walking across the deck, he would be left behind, and fall toward the stern. We must *suppose* a transverse force, and we must *suppose* the composition of this force without proof. This is no demonstration.

We apprehend, that the demonstration given above of this fundamental proposition is unexceptionable, when the terms force and deflection are used in the abstract sense which we have affixed to them. The only circumstance in it which can be the subject of discussion is, whether we have selected the proper measure and characteristic of a change of motion. We never met with any objection to it.

Objections to the demonstration of No. 45. It will not apply to pressures.

48. But some have still maintained that it does not evidently appear from these principles, that the motion which results from the joint action of two natural powers, whose known and measurable intensities have the same proportions with AB and BC, and which also exert themselves in those directions, will produce a motion having the direction and proportion of AD. They will not, if the velocities produced by these forces are not in the proportion of those intensities, but in the subduplicate ratio of them. Nay, they say that it is not so. If a body be impelled along AC by one spring, and along AB by two springs equally strong, it will not describe the diagonal of a parallelogram of which the side AB is double the side AC. They add, that an indefinite number of examples can be given where a body *does not* describe the diagonal of the parallelogram by the joint action of two forces, which separately would cause it to describe the sides. And lastly, they say that at any rate it does not appear evident to the mind, that two *incitements* to motion, having the directions and the same proportion of intensity with that of the sides of a parallelogram, actually generate a third, which is the immediate cause of the motion in the diagonal. An equivalent force is not the same with a resulting force.

49. Yet we see numberless cases of the composition of incitements to motion, and they seem as determinate and as susceptible of being combined by composition, as the things called moving forces, which are measured by the velocities. We see them actually so combined in a thousand instances, as in the example already given of a lighter dragged by two horses pulling in different directions. Experiment even shows, that this composition follows precisely the same rule as the composition of the forces which are measured by the velocities; for if the point A (fig. 1) be pulled by a thread or pressed by a spring in the direction AB, and by another in the direction AC, and if the pressures are proportional to AB and AC, then it will be withheld from moving, if it be pulled or pressed by a third force, acting in the direction A*d*, opposite to AD, the pressure being also proportional to AD. This force acting in the direction A*d*, would certainly withstand an equal force acting in the direction AD; therefore we must conclude that the two pressures AB and AC really generate a force AD. This uniform agreement shows that the composition is deducible from fixed principles; but it does not appear that it can be held as demonstrated by the arguments employed in the case of motions. A demonstration of the composition of pressures is farther

Second Law of Motion.

This composition is of more difficult investigation.

wanted, in order to render mechanics a demonstrative science.

Accordingly, philosophers of the first eminence have turned their attention to this problem. It is by no means easy; being so nearly allied to first principles, that it must be difficult to find axioms of greater simplicity by which it may be proved.

Mechanicians generally contented themselves with the solution given by Aristotle; but this is merely a composition of motions; indeed he does not give it for any thing else, and calls it συνθεσις των φυ ϙν. The first writer who appears to have considered it as different from the mere composition of motions, was the celebrated Dutch engineer Stevinus, in his work *on Sluices;* but his solution is obscure. It was sufficient, however, to convince Daniel Bernoulli of the necessity and the difficulty of the problem. He has given the first complete demonstration of it in the first volume of the commentaries of the Imperial Academy of Sciences at St Petersburg. It is extremely ingenious; but it is tedious and intricate, requiring a series of fifteen propositions to demonstrate that two pressures, having the directions and magnitudes of the sides of any parallelogram, compose a third, which has the direction and magnitude of its diagonal. His first proposition is, that *two equal pressures, acting at right angles, compose a third, in the direction of the diagonal of a square, and having to either of the other two the proportion of the diagonal of a square to its sides.*

M. d'Alembert has greatly simplified and improved this demonstration, by beginning with a case that is self-evident; namely, *if three equal forces are inclined to each other in equal angles of* 120°, *any one of them will balance the combined action of the other two.* Surely; for neither of them can prevail. Therefore *two* equal forces, inclined in an angle of 120°, produce a third, which has the direction and proportion of the diagonal of the rhombus; for this is equal and opposite to one of the three above mentioned. He then demonstrates the same thing of two equal forces inclined in *any* angle; and by a series of eight propositions more, demonstrates the general theorem. This dissertation is in the Memoirs of the Academy at Paris for 1769. He improves it still farther in a subsequent memoir.

Mr Riccati and Mr Fonsenex, in the Commentaries of me Academy of Turin, have given analytical demonstrations, which are also very ingenious and concise, but require acquaintance with the higher mathematics. There is another very ingenious demonstration in the *Journal des Sçavans* for June 1764, but too obscure for an elementary proposition. It is somewhat simplified by Belidor in his *Ingenieur François.* Frisius, in his *Cosmographia,* has given one, which is perhaps the best of all those that are easily comprehended without acquaintance with the higher mathematics; but we imagine that, although no one can doubt of the conclusion, it has not that intuitive evidence for every step of the process that seems necessary.

Composition of pressures.

50. We here offer another, composed by blending together the methods of Bernoulli and D'Alembert; and we imagine that no objection can be made to any step of it. We limit it entirely to pressures, and do not at all consider nor employ the motions which they may be supposed to produce.

(A.) If two equal and opposite pressures or incitements to motion act at once on a material particle, it suffers no change of motion; for if it yields in either direction by their joint action, one of the pressures prevails, and they are not equal.

Equal and opposite pressures are said to *balance* each other; and such as balance must be esteemed equal and opposite.

(B.) If a and b are two magnitudes of the same kind, proportional to the intensities of two pressures which act in the same direction, then the magnitude $a+b$ will measure the intensity of the pressure, which is equivalent, and may be called equal to the combined effort of the other two; for when we try to form a notion of pressure as a measurable magnitude, distinct from motion or any other effect of it, we find nothing that we can measure it by but another pressure. Nor have we any notion of a double or triple pressure different from a pressure that is equivalent to the joint effort of two or three equal pressures. A pressure a is accounted triple of a pressure b, if it balances three pressures, each equal to b, acting together. Therefore, in all proportions which can be expressed by numbers, we must acknowledge the legitimacy of this measurement; and it would surely be affectation to omit those which the mathematicians call *incommensurable.*

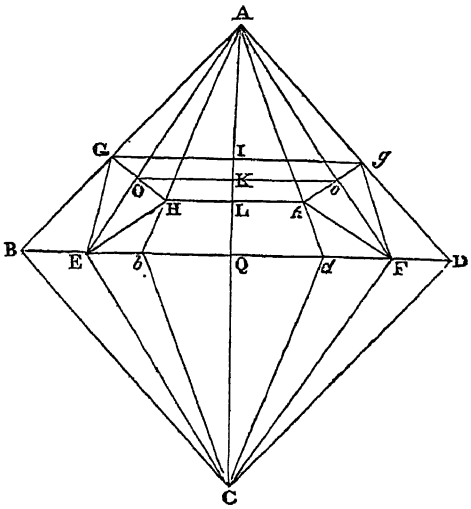
Second Law of Motion.

In like manner, the magnitude $a-b$ must be acknowledged to measure that pressure which arises from the joint action of two pressures a and b acting in opposite directions, of which a is the greatest.

(C.) Let ABCD and AbCd (fig. 2) be two rhombuses, which have the common diagonal AC. Let the angles BAb, DAd, be bisected by the straight lines AE and AF.

If there be drawn from the points E and F the lines EG, EH, Fg, Fh, making equal angles on each side of EA and FA, and if Gg, Hh be drawn, cutting the diagonal AC in I and L: then AI + AL will be greater or less than AQ, the half of AC, according as the angles GEH, gFh, are greater or less than GAH, gAh.

Fig. 2.



Draw GH, gh, cutting AE, AF, in O and o, and draw Oo, cutting AC in K.

Because the angles AEG and EAG are respectively equal to AEH and EAH, and AE is common to both triangles, the sides AG, GE, are respectively equal to AH, HE, and GH is perpendicular to AE, and is bisected in O; for the same reasons gh is bisected in o. Therefore the lines Gg, Oo, Hh, are parallel, and IL is bisected in K. Therefore AI + AL is equal to twice AK. Moreover, if the angle GEH be greater than GAH, AO is greater than EO, and AK is greater than KQ. Therefore AI + AL is greater than AQ; and if the angle GEH be less than GAH, AI + AL is less than AQ.

(D.) Two equal pressures, acting in the directions AB and AC (fig. 3), at right angles to each other, compose a pressure in the direction AD, which bisects the right angle; and its intensity is to the intensity of each of the constituent pressures as the diagonal of a square to one of the sides.

Second Law of Motion.

Fig. 3.

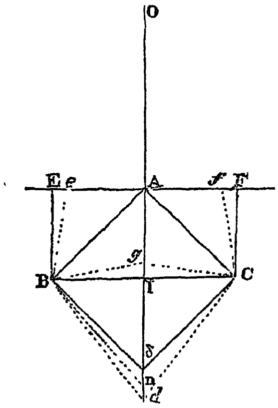


Fig. 4.

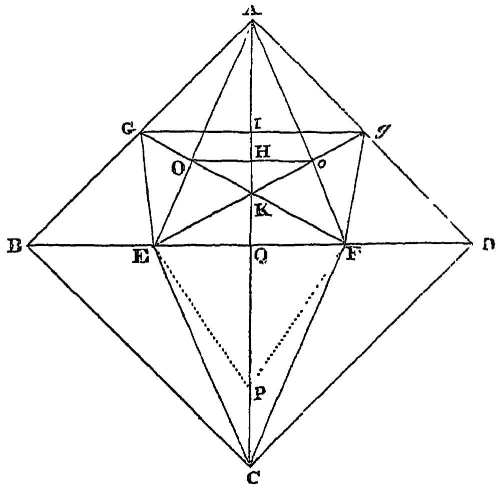


It is evident, that the direction of the pressure, generated by their joint action, will bisect the angle formed by their directions; because no reason can be assigned for the direction inclining more to one side than to the other.

In the next place, since a force in the direction AD does, in fact, arise from the joint action of the equal pressures AB and AC, the pressure AB may be conceived as arising from the joint action of two equal forces similarly inclined and proportioned to it. Draw EAF perpendicular to AD. One of these forces must be directed along AD, and the other along AE. In like manner, the pressure AC may arise from the joint action of a pressure in the direction AD, and an equal pressure in the direction AF. It is also plain that the pressures in the directions AE and AF, and the two pressures in the direction AD, must be all equal. And also, any one of them must have the same proportion to AB or to AC, that AB or AC has to the force in the direction AD, arising from their joint action.

Therefore, if it be said that AD does not measure the pressure arising from the joint action of AB and AC, let A*d*, greater than AD, be its just measure, and make A*d* : AB = AB : A*g* = AB : A*e*. Then A*g* and A*e* have the same inclination and proportion to AB that AB and AC have to A*d*. We determine, in like manner, two forces A*f* and A*g* as constituents of AC.

Now A*d* is equivalent to AB and AC, and AB is equivalent to A*e* and A*g*; and AC is equivalent to A*f* and A*g*. Therefore A*d* is equivalent to A*e*, A*f*, A*g*, and A*g*. But (A) A*e* and A*f* balance each other, or annihilate each other's effect; and there remain only the two forces or pressures A*g*, A*g*. Therefore (B) their measure is a magnitude equal to twice A*g*. But if A*d* be greater than the diagonal AD of the square, whose sides are AB and AC; then A*g* must be less than AI, the side of the square whose diagonal is AB. But twice A*g* is less than AD, and much less than A*d*. Therefore the measure of the equivalent of AB and AC cannot be a line A*d*, greater than AD. In like manner, it cannot be a line Aδ that is less than AD. Therefore it must be equal to AD, and the proposition is demonstrated.

(E.) *Cor.* Two equal forces, AB, AC, acting at right angles, will be balanced by a force AO, equal and opposite to AD, the diagonal of the square whose sides are AB and AC; for AO would balance AD, which is the equivalent of AB and AC.

(F.) Let AECF (fig. 4), be a rhombus, the acute angle of which, EAF, is half of a right angle. Two equal pressures, which have the directions and measures AE, AF, compose a pressure having the direction and measure AC, which is the diagonal of the rhombus.

It is evident, in the first place, that the compound force has the direction AC, which bisects the angle EAF. If AC be not its just measure, let it be AP less than AC. Let ABCD be a square described on the same diagonal, and make AP : AQ = AE : AO, = AF : A*o*. Draw KOG, K*og* perpendicular to AE, AF; draw GI*g*, OH*o*, EG, EK, F*g*, FK, PF, and PE.

The angles CAB and FAE are equal, each being half of a right angle. Also the figures AEPF and AGEK are similar; because AP : AQ = AE : AO. Therefore FA : AP = KA : AE, and EA : AP = GA : AE. Therefore, in the same manner that the forces AE, AF are affirmed to compose AP, the forces AG and AK may compose the force AE, and the forces A*g* and AK may compose the force AF. Therefore (B) the force AP is equivalent to the four forces AG, AK, A*g*, AK. But (D) AG and A*g* are the sides of a square, whose diagonal is equal to twice AI; and the two forces AK, AK are equal to, or are measured by, twice AK. Therefore the four forces AG, AK, A*g*, AK, are equivalent to 2 AI + 2 AK = 4 AH.

But because AP was supposed less than AC, the angle FPE is greater than FAE, and GEK is greater than GAK, AO is greater than OE, and AH is greater than HQ, and 2AH is greater than AQ; and therefore 4AH is greater than AC, and much greater than AP. Therefore AP is not the just measure of the force composed of AE and AF.

In like manner it is shown that AE and AF do not compose a force whose measure is greater than AC. It is therefore equal to AC; and the proposition is demonstrated.

(G.) By the same process it may be demonstrated, that if BAD be half a right angle, and EAF be the fourth of a right angle, two forces AE, AF will compose a force measured by AC. And the process may be repeated for a rhombus, whose acute angle is $\frac{1}{8}$th, $\frac{1}{16}$th, &c. of a right angle; that is, any portion of a right angle that is produced by continual bisection. Two forces, forming the sides of such a rhombus, compose a force measured by the diagonal.

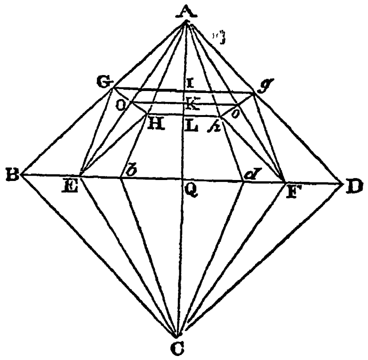
(H.) Let ABCD, A*b* C*d*, (fig. 5), be two rhombuses, formed by two consecutive bisections of a right angle. Let AECF be another rhombus, whose sides AE and AF bisect the angles BA*b* and DA*d*.

The two forces AE, AF, compose a force AC.

Bisect AE and AF in O and *o*. Draw the perpendiculars GOH, *goh*, and the lines GI*g*, OK*o*, HL*h*, and the lines EG, EH, F*g*, F*h*.

Second Law of Motion.

Fig. 5.



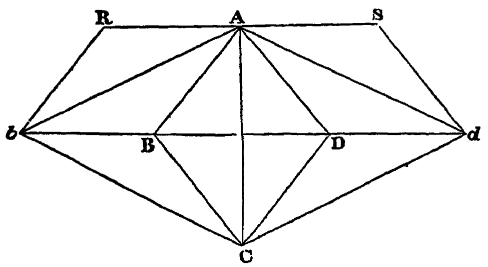
It is evident that AGEH and AgFh are rhombuses; because AO = OE, and Ao = oF. It is also plain, that since bAd is half of BAD, the angle GAH is half of bAd. It is therefore formed by a continual bisection of a right angle. Therefore (G) the forces AG, AH, compose a force AE; and Ag, Ah, compose the force AF. Therefore the forces AG, AH, Ag, Ah, acting together, are equivalent to the forces AE, AF, acting together. But AG, Ag compose a force = 2 AI; and the forces AH, Ah compose a force = 2 AL. Therefore the four forces acting together are equivalent to 2 AI + 2 AL, or to 4 AK. But because AO is $\frac{1}{2}$ AE, and the lines Gg, Oo, Hh, are evidently parallel, 4 AK is equal to 2 AQ, or to AC; and the proposition is demonstrated.

(I.) *Cor.* Let us now suppose that by continual bisection of a right angle we have obtained a very small angle a of a rhombus; and let us name the rhombus by the multiple of a, which forms its acute angle.

The proposition (G) is true of a, 2 a, 4 a, &c. The proposition (H) is true of 3 a. In like manner, because (G) is true of 4 a and 8 a, proposition (H) is true of 6 a; and because it is true of 4 a, 6 a, and 8 a, it is true of 5 a and 7 a. And so on continually till we have demonstrated it of every multiple of a that is less than a right angle.

(K.) Let RAS (fig. 6) be perpendicular to AC, and let ABCD be a rhombus, whose acute angle BAD is some multiple of 2 a that is less than a right angle. Let Ab, Cd be another rhombus, whose sides Ab, Ad bisect the angles RAB, SAD. Then the forces Ab, Ad compose a force AC.

Fig. 6.



Draw bR, dS parallel to BA, DA. It is evident that ARbB and ASdD are rhombuses, whose acute angles are multiples of a, that are each less than a right angle. Therefore (I) the forces AR and AB compose the force Ab and AS, AD compose Ad; but AR and AS annihilate each other's effect, and there remains only the forces AB, AD. Therefore Ab and Ad are equivalent to AB and AD, which compose the force AC; and the proposition is demonstrated.

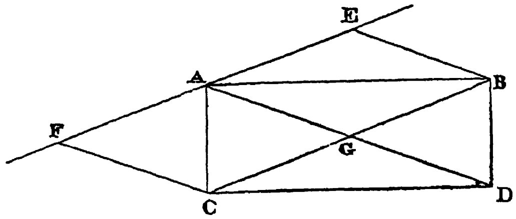
(L.) *Cor.* Thus is the corollary of last proposition extended to every rhombus, whose angle at A is some multiple of a less than two right angles. And since a may be taken less than any angle that can be named, the proposition may be considered as demonstrated of every rhombus; and we may say,—

Second Law of Motion.

(M.) *Two equal forces, inclined to each other in any angle, compose a force which is measured by the diagonal of the rhombus, whose sides are the measures of the constituent forces.*

(N.) Two forces AB, AC (fig. 7) having the direction and proportion of the sides of a rectangle, compose a force AD, having the direction and proportion of the diagonal.

Fig. 7.

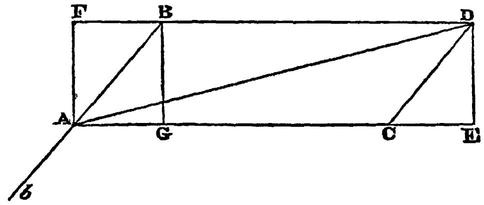


Draw the other diagonal CB, and draw EAF parallel to it: draw BE, CF parallel to DA.

AEBG is a rhombus; and therefore the forces AE and AG compose the force AB. AFCG is also a rhombus, and the force AC is equivalent to AF and AG. Therefore the forces AB and AC, acting together, are equivalent to the forces AE, AF, AG, and AG acting together, or to AE, AF, and AD acting together; but AE and AF annihilate each other's action, being opposite and equal (for each is equal to the half of BC). Therefore AB and AC acting together are equivalent to AD, or compose the force AD.

(O.) Two forces, which have the direction and proportions of AB, AC (fig. 8) the sides of any parallelogram, compose a force having the direction and proportion of the diagonal AD.

Fig. 8.



Draw AF perpendicular to BD, and BG and DE perpendicular to AC.

Then AFBG is a rectangle, as is also AFDE; and AG is equal to CE. Therefore (N) AB is equivalent to AF and AG. Therefore AB and AC acting together, are equivalent to AF, AG, and AC acting together; that is, to AF and AE acting together; that is (N) to AD; or the forces AB and AC compose the force AD.

51. Hence arises the most general proposition.

Composition of all incitements to motion.

If a material particle be urged at once by two pressures or incitements to motion, whose intensities are proportional to the sides of any parallelogram, and which act in the directions of those sides, it is affected in the same manner as if it were acted on by a single force, whose intensity is measured by the diagonal of the parallelogram, and which acts in its direction: Or, two pressures, having the direction and proportion of the sides of a parallelogram, generate a pressure having the direction and proportion of the diagonal.

52. Thus have we endeavoured to demonstrate from abstract principles the perfect similarity of the composition of pressures, and the composition of forces measured by the motions which they produce. We cannot help being of the opinion that a separate demonstration is indispen-

Second Law of Motion.

Seeming difference of the compositions of motion and of pressure disappear when carefully examined.

sably necessary. What may be fairly deduced from the one case cannot always be applied to the other. No composition of pressures can explain the change produced by a deflecting force on a motion already existing; for the changing pressure is the only one that exists, and there is none to be compounded with it. And, on the other hand, our notions and observations of the composition of motions will not explain the composition of pressures, unless we take it for granted that the pressures are proportional to the velocities; but this is perhaps a gratuitous assumption. At any rate, it is not an intuitive proposition; and we have mentioned some facts where it seems that they do not follow the same proportion. The pressure of four equal springs produces only a double velocity. It would appear, therefore, that there are circumstances which oblige us to say, that the *exertion* of pressure, as a cause of motion, is not (always at least) proportional to the real measurable pressure. We are therefore anxious to discover in what the difference consists; and in the mean time must allow, that the pressure exerted on a body at rest is different from its exertion in producing motion. We cannot indeed state any immediate comparison between pressure and motion, nor have we any clear conception of the connection between them. It is only by our own sensations of touch that we have any notion of pressure, and it is experience that teaches us that it always accompanies every cause of motion. We can, however, observe the proportions of pressures, and compare them with the proportions of motion. We very often observe them different; and therefore it was indispensably necessary to investigate the laws of combined pressure as we did the laws of combined motion in consequence of pressure. Yet we should err if we hastily asserted that pressures are not proportional to the motions which they produce; all that we are entitled to call in doubt is, whether the pressures in their exertion, while they actually produce motion, or changes of motion, continue to be the same as when they do not produce motion, being withstood or balanced by opposite pressures. Considered as causes of motion, we ought to think that they do not vary while they produce motion, and that the actual pressure, while it produces a double motion, is really double, although it may be quadruple when the body exerting it is made to act on a body that it cannot move. We are confirmed in this opinion by observing, that other facts show us, that even while producing motion, the pressure which we call quadruple, because we have measured it by four equal pressures balancing it, is really quadruple, considered as the cause of motion, and produces a quadruple motion. A bow which requires four times the force to draw it to any given extent, will communicate the same velocity to a bundle of four arrows that a bow four times more easily drawn communicates to one arrow, and will therefore produce a quadruple motion. Yet it will only produce a double velocity in the arrow that acquired a simple velocity from a bow having one fourth of the strength.

These discrepancies should excite the endeavours of mechanicians to investigate the laws observed in the action of pressures producing motion. Had this been done with care and with candour, we should not have had the great difference of opinion which still divides philosophers about the measures of moving forces. But a spirit of party, which had arisen from other causes, gave importance to what was at first only a difference of expression, and made the partizans of Mr Leibnitz avail themselves of the figurative language which has done so much harm in all the departments of philosophy. Notwithstanding all our caution, it is hardly possible to avoid metaphorical conceptions when we employ the language of metaphor. The abettors of the Leibnitzian measure of moving forces, or perhaps, to speak more properly, the abettors of the Leibnitzian measure of that force which is supposed to preserve bodies in their condition of motion, insist that the force which is exerted in producing any change of motion is greater in proportion as the motion changed is greater; and they give a very specious argument for their assertion. They appeal to the exertions which we ourselves make. Here we are conscious of the fact. Then they give similar examples of the action of bodies. A clay ball, moving six feet per second, will make the addition of one foot to the velocity of an equal clay ball that is already moving four feet per second in the same direction. But if this last ball be already moving ten feet per second, we must follow it with a velocity of twelve feet in order to increase its velocity one foot. But, without insisting on the numberless paralogisms and inconsistencies which this way of conceiving the matter would lead us into, it suffices to observe, that the phenomena give us abundant assurance that there has been the same exertion in both these cases. This acceleration is always accompanied by a compression of the balls, and the compression is the same in both. This compression is a very good measure of the force employed to produce it; and, in the present case, we need not even trouble ourselves with any rule for its measurement: for surely, when the compression is not different, but the same, the force exerted is the same. This is farther confirmed by observing, that it requires the same force to make the same pit, or to give the same motion, to a piece of clay lying on the table of a ship's cabin, whether the ship be sailing two miles or ten miles per hour.

Thus we see that there are strong reasons for believing, that the exertions of pressure in producing motion, or that the pressures *actually exerted*, are proportional to the changes of motion observed, and that they coincide in this respect with our abstract conceptions of moving forces.

But we have still better arguments. None of the Leibnitzians think of denying the equal exertions of gravity, or of any of those powers which they call *solicitations or accelerating forces.* They all admit that gravity, or any constant accelerating force, produces equal increments of velocity in equal times, and that a double gravity will produce a double increment in an equal time, and an equal increment in half of the time: and that a quadruple gravity will produce a double velocity in half the time. All these things are granted by them, and their writings are full of reasonings from this principle. Now, from the fact, acknowledged by the Leibnitzians, that the quadruple force of a bow gives a double velocity to the arrow, in every instant of its action, it indisputably follows, that it has acted on it only for half the time of the action of the four times weaker bow, which gives the arrow only half the velocity; and thus has the discrepancy between the effects of pressures and of our abstract moving forces entirely disappeared. For this circumstance of the difference in the time of acting will be found, on strict examination, in all the cases of the change of motion by pressures which we measure by their effects on a body at rest. When this and the appreciable changes of actual pressure, during the time of producing the motion, are taken into consideration, all difference vanishes, and the composition of pressures is in perfect harmony with the composition of motions, or of abstract moving forces. Dynamics is thus made a demonstrative science, and affords the opportunity of investigating, by observation and experiment, the nature of those mechanical powers which reside in bodies, and which appear to us under the form of pressure, inducing us to consider pressure as a cause of motion.

In this, however, we are rather inaccurate. Pressure is one of the sensible effects of that property which is also

Second Law of Motion.

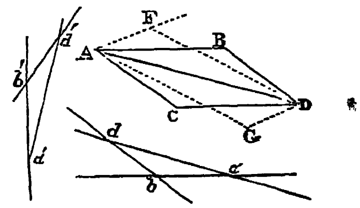
the cause of motion. It is not the pressure of a piece of lead, but its heaviness, that is the reason that it gives motion to a kitchen jack. Pressure is merely a generic name, borrowed from a similar instance, and given to moving forces, which have the same nature, but different names that serve to mark their connection with certain substances, in which they may be supposed to reside. Natural philosophy is almost entirely employed in examining the nature of these various pressures or accelerative forces; and the general doctrines of dynamics, by ascertaining what is common to them all, enable us to mark with precision what is characteristic of each.

General corollaries.

53. We have now advanced very far in this investigation; for we have obtained the criterion by which we learn the direction and the magnitude of every changing force; and, on the other hand, we see how to state what will be the effect of the exertion of any force that is known or suspected to act. All this we learn by the composition of forces; and the greatest part of mechanical disquisition consists in the application of this doctrine. For such reasons it merits minute consideration; and therefore we must point out some general conclusions from the properties of figure, which will greatly facilitate the use of the parallelogram of forces.

54. *First,* The constituent and the resulting forces, or the simple and compound forces, act in the same plane; for the sides and diagonal of a parallelogram are in one plane.

Fig. 9.



55. *Second,* The simple and the compound forces are proportional to the sides of any triangle which are parallel to their directions. For if any three lines, *ab*, *bd*, *ad*, be drawn parallel to AB, AC, and AD (fig. 9), they will form a triangle similar to the triangle ABD. For the same reasons they are proportional to the sides of a triangle *a'b'd*, which are respectively perpendicular to their directions.

56. *Third,* Therefore each is proportional to the sine of the opposite angle of this triangle; for the sides of any triangle are proportional to the sines of the opposite angles.

57. *Fourth,* Each is proportional to the sine of the angle contained by the directions of the other two; for AD is to AB as the sine of the angle ABD to the sine of the angle ADB. Now the sine of ABD is the same with the sine of BAC contained between the directions AB and AC, and the sine of ADB is the same with the sine of CAD; also AB is to AC, or BD, as the sine of ADB (or CAD) to the sine of BAD.

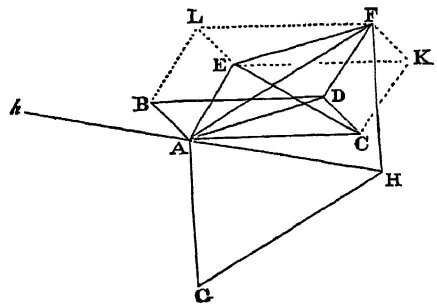
Some special uses of the parallelogram of forces.

58. We now proceed to the application of this fundamental proposition. And we observe, in the first place, that since AD may be the diagonal of an indefinite number of parallelograms, the motion or the pressure AD may result from the joint action of many pairs of forces. It may be produced by forces which would separately produce the motions AF and AG. This generally gives us the means of discovering the forces which concur in its production. If one of them, AB, is known in direction and intensity, the direction AC, parallel to BD, and the intensity, are discovered. Sometimes we know the directions of both. Then, by drawing the parallelogram or triangle, we learn their proportions. The force which deflects any motion AB into a motion AD, is had by simply drawing a line from the point B (to which the body would have moved from A in the time of really moving from A to D) to the point D. The deflecting force is such as would have caused the body move from B to D in the same time. And, in the same manner, we get the compound motion AD, which arises from any two simple motions AB and AC, by supposing both of the motions to be accomplished in succession. The final place of the body is the same, whether it moves along AD or along AB and BD in succession.

Equivalent of many forces.

59. This theorem is not limited to the composition of two motions or two forces only; for since the combined action of two forces puts the body into the same state as if their equivalent alone had acted on it, we may suppose this to have been the case, and then the action of a third force will produce a change on this equivalent motion. The resulting motion will be the same as if only this third force and the equivalent of the other two had acted on the body. Thus, in fig. 10, the three forces AB, AC, AE, may act at once on a particle of matter. Complete the parallelogram ABDC; the diagonal AD is the force which is generated by AB and AC. Complete the parallelogram AEFD; the diagonal AF is the force resulting from the combined action of the forces AB, AC, and AE. In like manner, completing the parallelogram AGHF, the diagonal AH is the force resulting from the combined action of AB, AC, AE, and AG, and so on of any number of forces.

Fig. 10.



This resulting force and the resulting motion may be much more expeditiously determined, in any degree of composition, by drawing lines in the proportion and direction of the forces in succession, each from the end of the preceding. Thus, draw AB, BD, DF, FH, and join AH; AH is the resulting force. The demonstration is evident.

60. It is to be noticed here, that in the composition of more than two forces, we are not limited to one plane. The force AD is in the same plane with AB and AC; but AE may be elevated above this plane, and AG may lie below it. AF is in the plane of AD and AE, and AH is in the plane of AF and AG.

Complete the parallelograms ABLE, ACKE, ELFK. It is evident that ABLFKCD is a parallelopiped, and that AF is one of its diagonals. Hence we derive a more general theorem of great use.

Three forces having the proportion and direction of the three sides of a parallelopiped, compose a force having the proportion and direction of the diagonal.

One force may balance many acting together.

61. Any number of forces acting together on one particle of matter are balanced by a force that is equal and opposite to their resulting force; for this force would balance their resulting force which is equivalent to them in action. When this is duly considered, we perceive that each force is then in equilibrio with the equivalent of all

Second Law of Motion.

the others; for a force can balance only what is equal and opposite to it. It appears very readily by the geometrical construction. If, instead of the circuit A, B, D, F, H, we take B, D, F, H, A, we have BA for the equivalent of the forces AC, AE, AG; but AB is equal and opposite to BA. Therefore the force AB is in equilibrio with the equivalent of all the others.

62. When any number of forces act on one particle of matter, and are in equilibrio, if they be considered as acting in parcels, the equivalents of these parcels are in equilibrio; for let the forces AB, AC, AE, AG, A*h*, be in equilibrio, and let them be considered in the two parcels AB, AC, and AE, AG, A*h*, then AD is the equivalent of AB, BD (or AC), and DA is the equivalent of DF, FH, HA (or A*h*): now AD and DA balance each other. This corollary enables us to simplify many intricate complications of force; it also enables us to draw accurate conclusions from very imperfect observations. In most of our practical discussions we know, or at least we attend to, a part only of the forces which are acting on a material particle; and in such cases we reason as if we saw the whole: yet is our mathematical reasoning good with respect to the equivalent of all the parcels which we are contemplating, and the equivalents of the smaller parcels of which it consists; and the neglected force, or parcel of forces, induces no error on our conclusions.

Expeditious methods for obtaining the resulting motion in complicated cases.

63. In the spontaneous phenomena of nature, the investigation and discovery of our ultimate object of search is frequently very difficult, on account of the multiplicity of directions and intensities of the operating forces or motions. We may generally facilitate the process, by substituting equivalent forces or motions acting in convenient directions. It is in this way that the navigator computes the ship's place with very little trouble, by substituting equivalent motions in the meridional and equatorial directions for the real oblique courses of the ship. Instead of setting down ten miles on a course, S. 36° 52′ W. he supposes that the ship has sailed eight miles due south, and six miles due west, which brings her near to the same place. Then, instead of fourteen miles south-west, he sets down ten miles south and ten miles west; and he proceeds in the same way for every other course and distance. He does this expeditiously by means of a traverse table, in which are ready calculated the meridional and equatorial sides of right-angled triangles, corresponding to every course and distance. Having done this for the course of a whole day, he adds all the southings into one sum, and all the westings into another; he considers these as forming the sides of a right-angled triangle; he looks for them, paired together, in his traverse table, and then notices what angle and what distance corresponds to this pair. This gives him the position and magnitude of the straight line joining the beginning and end of his day's work.

The miner proceeds in the same way when he takes the plan of subterraneous workings, measuring, as he goes along, and noticing the bearing of each line by the compass, and setting down, from his traverse table, the northing or southing, and the easting or westing, for each oblique line: but there is another circumstance which he must attend to, namely, the slope of the various drifts, galleries, and other workings. This he does by noting the rise or the dip of each sloping line. He adds all these into two sums, and taking the risings from the dips, he obtains the whole dip. Thus he learns how far the workings proceed to the north, how far to the east, and how far to the dip.

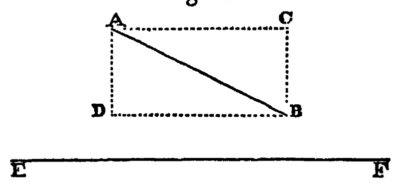
The reflecting reader will perceive that the line joining the two extremities of this progression will form the diagonal of a rectangular parallelopiped; one of whose sides lies north and south, the other lies east and west, and the third is right up and down.

The mechanician proceeds in the very same way in the investigation of the very complicated phenomena which frequently engage his attention. He considers every motion as compounded of three motions in some convenient directions, at right angles to each other. He also considers every force as resulting from the joint action of three forces, at right angles to each other, and takes the sum or difference of these in the same or opposite directions. From this process he obtains the three sides of a parallelopiped, and from these computes the position and magnitude of the diagonal. This is the motion or force resulting from the composition of all the partial ones.

Forces may be estimated by, or reduced to

This procedure is called the *estimation* or *reduction* of motions and forces.

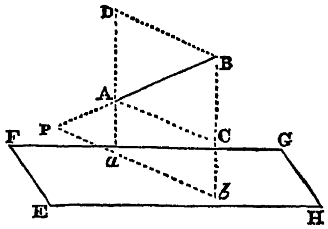
Fig. 11.



a given direction,

64. A motion or force AB (fig. 11) is said to be *estimated* in the direction EF, or to be *reduced* to this direction when it is conceived as compounded of the motions or forces AC, AD, one of which, AC, is parallel to EF, and the other, AD, is perpendicular to it. This expression is abundantly significant; for it is plain that the motion AD neither promotes nor hinders the progress along EF, and that AC expresses the whole progress in this direction.

Fig. 12.



or a given plane.

65. In like manner, a force AB (fig. 12) is said to be *estimated in*, or *reduced to*, a given plane EFGH, when it is conceived as resulting from the joint action of two forces AC, AD, one of which is parallel to a line *ab* drawn in that plane, and the other AD is perpendicular to it. The position of the line *ab* is determined by letting fall B*b* perpendicular to the plane, and drawing *b*P to the point P, in which BA meets the plane; then A*a* being drawn parallel to B*b*, will cut off *ba*, which is the reduction of the motion AB to the plane. Drawing AC parallel to *ab*, and completing the parallelogram ACBD, it is evident that the motion AB is equivalent to AD and AC, which is parallel to *ab*, and the three forces AB, AC, AD, are, as they should be, in one plane perpendicular to the plane EG.

Equilibrium of forces so estimated or reduced

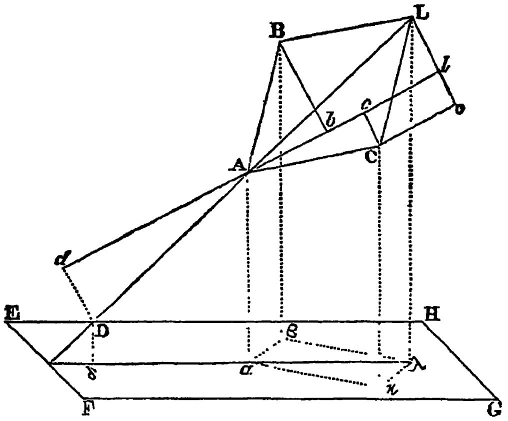
66. If three forces AB, AC, AD (fig. 13) are in equilibrio, and are reduced to any one direction *d*A*l*, or to one plane EFGH, the reduced forces are also in equilibrio.

First, let them be reduced to one direction *dl* by drawing the perpendiculars B*b*, C*c*, D*d*; make AL equal to AD, and join BL, CL, and draw the perpendiculars L*l*, C*c*; then, because the forces AB, AC, AD, are in equilibrio, ABLC must be a parallelogram, and AL is the force equivalent to AB and AC combined; then, because the lines D*d*, B*b*, C*c*, L*l*, are parallel, *d*A is equal to A*l*, and A*b* to C*o*, or to *cl*; therefore A*l* is equal to the sum of A*b* and A*c*, which are the reductions of AB and AC;

Second Law of Motion.

therefore dA is equal to the same sum, and in equilibrio with them.

Fig. 13.



Secondly, Let them be reduced to one plane, EFGH, and let $\alpha\beta$, αx, $\alpha\delta$, be the reduced forces. The lines $D\delta$, $A\alpha$, $B\beta$, Cx, $L\lambda$, are all parallel, being perpendicular to the plane; therefore the planes AB, $\beta\alpha$, and CL, λx, are parallel, and $\alpha\beta$, $x\lambda$, are parallel. For similar reasons, $\beta\lambda$, αx, are parallel; therefore $\alpha\beta\lambda x$ is a parallelogram. Also, because the lines $D\delta$, $A\alpha$, $L\lambda$, are parallel, and DA is equal to AL; therefore $\delta\alpha$ is equal to $\alpha\lambda$. But because $\alpha\beta\lambda x$ is a parallelogram, the forces $\alpha\beta$, αx, are equivalent to $\alpha\lambda$; and $\alpha\delta$ is equal and opposite to $\alpha\lambda$, and will balance it; and therefore will balance $\alpha\beta$ and αx, which are the reductions of AB and AC to the plane EFGH, while $\alpha\delta$ is the reduction of AD; therefore the proposition is demonstrated.

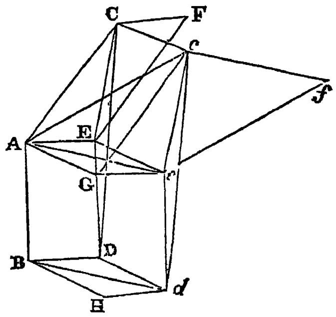
The most useful mode of reduction is to their co-ordinates.

The most usual and the most useful mode of reduction is to estimate all forces in the directions of three lines drawn from one point, at right angles to each other, like the three plane angles of a rectangular chest, forming the length, the breadth, and the depth of the chest. These are commonly called the three co-ordinates. The resulting force will be the diagonal of this parallelopiped. This process occurs in all disquisitions in which the mutual action of solids and fluids is considered, and when the oscillation or rotation of detached free bodies is the subject of discussion.

Relative motions of bodies not affected by any extraneous equal and parallel force.

67. The only other general theorem that remains to be deduced from this law of motion is, that if a number of bodies are moving in any manner whatever, and an equal force act on every particle of matter in the same or parallel directions, their relative motions will suffer no change;

Fig. 14.



for the motion of any body A (fig. 14), relative to another body B, which is also in motion, is compounded of the real motion of A, and the opposite to the real motion of B; for let A move uniformly from A to C, while B describes BD uniformly; draw AB, also draw AE equal and parallel to BD; join EC, DC, ED. The motion of A, relative to B, consists in its change of position and distance. Had A described AE, while B described BD, there would have been no change of relative place or distance; but A is now at C, and DC is its new direction and distance. The relative or apparent motion of A therefore is EC. Complete the parallelogram ACFE; it is plain that the motion EC is compounded of EF, which is equal and parallel to AC, the real motion of A, and of EA, the equal and opposite to BD, the real motion of B.

Now let the motions of A and B sustain the same change; let the equal and parallel motions AG, BH, be compounded with the motions AC and BD; or let forces act at once on A and B, in the parallel directions AG, BH, and with equal intensities; in either supposition, the resulting motions will be Ac, Bd, the diagonals of the parallelograms AGcC and BHdD. Construct the figure as before, and we see that the relative motion is now ec, and that it is the same with EC both in respect of magnitude and position.

Here we still see the constant analogy between the composition of motions and the composition of forces. In the first case, the relative motions of things are not changed, whatever common motion be compounded with them all; or, as it is usually but inaccurately expressed, although the space in which they move be carried along with any motion whatever. In the second case, the relative motions and actions are not changed by any external force, however great, when equally exerted on every particle in parallel directions.

Thus it is that the evolutions of a fleet in a uniform current are the same, and produced by the same means, as in still water. Thus it is that we walk about on the surface of this globe in the same manner as if it neither revolved round the sun, nor turned round its axis. Thus it is that the same strength of a bow will communicate a certain velocity to an arrow, whether it is shot east, or west, or north, or south. Thus it is that the mutual actions of sublunary bodies are the same, in whatever directions they are exerted, and notwithstanding the very great changes in their velocities by reason of the earth's rotation and orbital revolution. The real velocity of a body on the earth's equator is about 3000 feet per second greater at midnight than at mid-day. For at midnight the motion of rotation nearly conspires with the orbital motion, and at mid-day it nearly opposes it. The difference between the velocities at the beginning of January and the beginning of July is vastly greater. And at other times of the day, and other seasons of the year, both motions of the earth are transversely compounded with the easterly or westerly motion of an arrow or cannon bullet; yet we can observe no change in the effects of the mutual actions of bodies.

This affords a demonstration of the proportionality of moving forces to the motions produced by them.

68. This is an important observation, because it proves that forces are to be measured by no other scale than by the motions which they produce. We have had repeated occasions to mention the very different estimation of moving forces by Mr Leibnitz; and have shown how, by a very partial consideration of the action of those natural powers called *pressures*, he has attempted to prove that moving forces are proportional to the squares of the velocities; and we showed briefly in what manner a right consideration of what passes when motion is produced by measurable pressures, proves that the forces really exerted are as the velocities produced. But the most copious proof is had from the present observation, that, in fact, the mutual actions of bodies depend on their relative motions alone.

69. The Leibnitzian measure of moving force is altogether incompatible with the universal fact now mentioned,

Second Law of Motion.

and is incompatible with their proportionality to the squares of those motions.

viz. that the relative motions of bodies, resulting from their mutual actions, are not affected by any common motion, or the action of any equal and parallel force on both bodies; for this universal fact imports, that when two bodies are moving with equal velocities in the same direction, a force applied to one of them, so as to increase its velocity, gives it the same motion relative to the other, as if both bodies had been at rest. Here it is plain that the space described by the body in consequence of the primitive force, and of the force now added, is the sum of the spaces which each of them would generate in a body at rest. Therefore the forces are proportional to the velocities or changes of motion which they produce, and not to the squares of those velocities. This measure of forces, or the position that a force makes the same change on any velocity whatever, and the independence of the relative motions on any motion that is the same on all the bodies of a system, are counterparts of each other. Since this independence is a matter of observation in all terrestrial bodies, we are entitled to say that the powers which the Author of nature has imparted to natural bodies are no way different from what are competent to matter once called into existence. And it also follows from this, that we must always remain ignorant of the absolute motions of bodies. The fact that it has required the unremitted study of ages to discover even the relative motions of our solar system, is an argument to prove that the influence of this mechanical principle extends far beyond the limits of this sublunary world; nor has any phenomenon yet been exhibited which should lead us to imagine that it is not universal.

So Bernoulli's defence of this last opinion is without force.

When we have made use of these arguments with some zealous partizans of Mr Leibnitz's doctrine, they have answered, that if indeed this independence of the relative motions of terrestrial bodies were observed to obtain exactly, it would be a conclusive argument. But the motion with which all is carried along is so great in comparison with the motions which we can produce in our experiments, that the small additions or diminutions that we can make to the velocity of this common motion must observe very nearly the proportions of the additions or diminutions of their squares. The differences of the squares of 2, 3, and 4, are very unequal; but the differences of the squares of 9, 10, 11, are much nearer to the ratio of equality; and the differences of the squares of 1000001, 1000002, 1000003, do not sensibly deviate from this ratio. But it is not fact that we cannot produce motions which have a very sensible proportion to the common motion. The motion of a cannon ball discharged with one third of its weight of powder, is nearly equal to that of the rotation of the earth's equator. When, therefore, we discharge the ball eastward, we double its motion; when to the westward, we destroy it. Therefore, according to Leibnitz, the action in the first case is three times the action in the second. In the first case it changes the square of the velocity (which we may call 1) from 1 to 4; and, in the second, it changes it from 1 to 0. But, say the Leibnitzians, the velocity of rotation is but $\frac{1}{63}$ of the orbital velocity of the earth, and our observations of the velocities of cannon bullets are not sufficiently exact to ensure us against an error of $\frac{1}{31\frac{1}{2}}$. But the latter observations on the peculiar motions of the fixed stars concur in showing, that the sun, with his attending planets, are carried along with a very great motion, which, in all probability, has a sensible ratio to the orbital motion of the earth. This must make a prodigious change on the earth's absolute motion, according as her orbital motion conspires with, opposes, or crosses, this other motion; the earth may even be at absolute rest in some points of its orbit. Thus will the composition with the motions produced in our experiments be so varied that cases *must* occur when the difference of the results of the two measures of force will be very sensible.

But, further, they have not attended to the agreement of our experiments when the discharges of cannon are made in a direction transverse to that of the common motion. Here the immensity of the common motion, and the minuteness of our experimental velocities, can have no effect in diminishing the difference of the results of the two doctrines. This will appear distinctly to every reader who is much conversant in disquisitions of this kind; and it is in these more moderate motions that the complete independence of the relative motions on the common motions most accurately appears. Pendulum clocks and watches have been often executed which do not deviate from perfect equability of motion one part in 86,400. This could not be obtained in all directions of the oscillations, if the forces deviated from the ratio of the velocities one part in 86,400.

Perfect agreement of the abstract notion of force with all our accurate observations of the exertions of natural powers.

On the whole, we may consider it as established on the surest foundation, that the action of those powers of natural bodies which we call *pressures*, such as the force of springs, the exertions of animals, the cohesion of bodies, as well as the action of those other incitements to motion which we call *attractions* and *repulsions*, such as gravitation, magnetism, and electricity, is proportional to the change of velocity produced by it. And we must observe here, that this is not a mere mode of conception, the result of the laws of human thought, which cannot conceive a natural power as the cause of motion otherwise than by its producing motion, and which cannot conceive any degree of *moving* power different from the degree of the motion. This is the abstract doctrine, and is true whether the pressures are proportional to the velocities or to the squares of the velocities.

But we see further, that whatever is the pressure of a spring (for example) on a quiescent body, yet the pressure actually exerted in producing a double velocity is only double, and not quadruple, as our first imperfect observations make us imagine.

Newton's third law of motion is founded on experience alone, and is not a necessary truth.

70. Sir Isaac Newton has added another proposition to the number of laws of motion; namely, that *every action is accompanied by an equal and contrary re-action.* But in affirming this to be a law of nature, he only means that it is a universal fact: and he makes this affirmation on the authority of what he conceives to be a law of human thought; namely, that those qualities which we find in all bodies on which we can make experiments and observations, are to be considered as universal qualities of body. But we have limited the term *law of motion* to those consequences that necessarily flow from our notions of motion, of the causes of its production and changes. Now this third Newtonian proposition is not such a result. A magnet is said to act on a piece of iron, when, and only when, the vicinity of the magnet is observed to be accompanied by certain motions of the iron. But it by no means follows from this observation, that the presence of the iron shall be accompanied by any motion, or any change of state whatever of the magnet, or any appearance that can suggest the notion that the iron acts on the magnet. When this was observed, it was accounted a discovery. Newton *discovered* that the sun acts on the planets, and that the earth acts on the moon; and Kepler *discovered* that the moon re-acts on the earth. Newton had observed that the iron re-acts on the magnet; that the actions of electrified bodies were mutual; and that every action of sublunary bodies was, in fact, accompanied by an equal and contrary re-action. On the authority of his rule of philosophizing, he affirmed that the planets re-act on the sun, and that the sun is not at rest, but is continually agi-

Second Law of Motion.

tated by a small motion round the general centre of gravitation. He pointed out several consequences of this re-action. Astronomers examined the celestial motions more narrowly, and found that those consequences do really obtain, and disturb all the planetary motions. It is now found that this reciprocity of action obtains throughout the solar system with the utmost precision, and that the third Newtonian proposition is really a law of nature, although it is not a law of human thought. It is a discovery. The contrary involves no absurdity or contradiction. It would indeed be contrary to experience; but things might have been otherwise. It is conceivable and possible that a ball A shall strike another equal ball B, and carry it along with it, without any diminution of its velocity. The fact that the velocity of A is reduced to one half, is the indication of a force residing in B, which force changes the motion of A; and the intensity of this force is learned from the change which it produces. This is found to be equal to the change produced by A on B. And thus the re-action of B is *discovered* to be equal to the action of A.

It is highly probable that this universality and equality of re-action to action is the consequence of some general principle, which we may in time discover; meanwhile we are entitled to suppose it universal, and to reason from this topic in our disquisitions about the actions of bodies on each other.

Maupertuis, Leibnitz, and other philosophers, have entertained very inadequate opinions concerning the foundation of the laws of motion.

Although the celebrated philosophers of Europe have at last agreed in the reception of the two propositions so largely discussed by us as the laws of motion, they have differed exceedingly in their opinion about their origin and validity. Some asserted that they are entirely matters of experience, while others affirmed them to be necessary truths. The Royal Academy of Berlin made this question the subject of their prize dissertation in the year 1744. Mr Maupertuis, president of the academy, published a dissertation, in which he endeavoured to prove that they are necessary truths, only because *they are such as make the quantity of action the least possible*, an economy which is worthy of infinite wisdom, and therefore certainly directs the choice of the Author of nature. On this account alone are they necessary truths.

But this is not the way to consider a question of this kind. We know too little about infinite wisdom to be able to say, with Messrs Leibnitz and Maupertuis, that the Deity should or should not impress on bodies laws different from those which are essential to matter; and we are not to inquire whether God could or could not do this. We know from our own experience, that matter, when subjected to the action of intelligence, may be moved in a way extremely different from what it would follow if left to itself, and that its motions may either be regulated by fixed but contingent law, or may be without any constancy whatever, and vary in every instance. When we suppose the existence of matter and motion, a variety of truths are involved in the supposition, in the same manner as all the theorems in the third book of Euclid's *Elements* are involved in the conception of a circle and a straight line. Our first employment should be to evolve those truths. We can do this in no way but by first noticing the relations of the ideas that we have of the different objects of contemplation, and then following the laws of human thought in our judgments concerning those relations. This process of the mind is expressed in the train of a geometrical demonstration. The different parts or argumentations of this train are not the causes of our conclusions, but the means by which we form our judgment; not the reasons of the truth of our ultimate conclusion, but the steps by which we arrive at the knowledge of it. The young geometer generally thinks otherwise. But that this is the matter of fact, is plain from this, that more than one demonstration, and often very different, can be given of the same theorem. We must proceed in the same manner in the present question; and the first general truths which we find involved in the notions of matter, motion, and force, must be received as *necessary* truths. The steps by which we arrive at the discovery are the laws of human thought; and the expression of the discovery, involving both the truth itself, and the manner of conceiving it, is a necessary law of motion. There may be other facts, perhaps as general as any of those necessary laws, but which do not necessarily result from the relations of our notions of motion and of force. These are discovered by observation only, and they serve to characterize the forces which nature presents to our view. These facts are *contingent* laws of motion.

We apprehend that this method has been followed in treating this article. The first proposition, termed *a law of motion*, is only a more convenient way of expressing our contemplation of a motion in body as an effect of the general cause which we term *force*. The second proposition does nothing but express more distinctly the relation between this cause and its effect; it expresses what we mean by the magnitude and the kind of the cause. The proposition, stating the composition of forces, is but another form of the same law, better suited to the ordinary procedure in geometrical disquisitions.

These propositions might have completed the doctrines of dynamics; but it appears that, in order to the production of a material universe which should accomplish the purposes of the Creator, it was necessary that there be certain characteristic differences between the forces inherent in the various collections of matter which compose this universe. The facts or physical laws (for the above-mentioned laws are metaphysical) of motion may be different from those which would have been observed had matter been left entirely to itself. This difference may have introduced other laws of motion as necessarily resulting from the nature of the forces. We have occasionally mentioned some instances where this appears to obtain, but gave good reasons for affirming that a due examination of all circumstances which may be observed in the production or variation of motion by those forces, has demonstrated, that there are no such deviations from the two laws of motion already determined, but that all the mechanical powers of bodies, when considered merely as causes of motion, act agreeably to the same laws. Careful examination was, however, said to be necessary.

This examination must consist in distinctly noticing the circumstances that occur in the production of motion by any force whatever. It is by no means enough to state simply the intensity of the force and the direction of its exertion. If a force continue to act, it continues to vary the motion already produced. Should the force change its intensity or direction while it is acting, these circumstances must induce still farther changes in the motion; and it is not till all action has ceased that the motion is brought to its ostensible state, in which it is the object of our attention and our future discussions. Instances of the effects of such continued and such varied actions are to be seen in most of the phenomena of nature or art. The communication of motion by impulse is perhaps the only instance (very frequent indeed) that can be produced where this is not necessary; nay, we shall perhaps find reason to conclude that this instance is not an exception, and that even the communication of motion from one billiard ball to another is brought about by an action continued for some time, and greatly varied during that time. Much preparation is therefore necessary before we can apply the

Of Accelerated and Retarded Motions.

general laws of motion to the solution of most of the questions which come before us in the course even of our elementary disquisitions. We must lay down some general propositions which determine the results of the continued, and perhaps varied, actions of moving forces; and we must mark the different effects of the simple continuation of action, and also those of the variations in this continued action, both in respect of intensity and direction. The effect of a mere continuance of action must be an acceleration of the motion, or a retardation of it if the force continue to act in the opposite direction. The effect of the continued action of a transverse force must be a continual deflection, that is, a curvilineal motion. These must therefore now occupy our attention in their order.

OF ACCELERATED AND RETARDED MOTIONS.

Circumstantial exposition of our conception of the condition of a body in respect to motion.

71. All men can perceive that a stone dropped from the hand, or sliding down an uniform slope, has its motion continually accelerated, and that the motion of an arrow rising perpendicularly through the air is continually retarded; and they feel no difficulty in conceiving these changes of motion as the effects of the continual operation of their weight or heaviness. The falling stone is in a different condition in respect of motion in the beginning and end of its fall. In what respect do these states of the body differ? Only in respect to what we call its *velocity*. This is an affection of motion; it is an expression of the relation between the two notions or ideas which concur to form the idea of motion, namely, the space and the time. These are all the circumstances that we observe in a motion. Time elapses, and during its currency a space is described. The term *velocity* expresses the magnitude of the space, which corresponds to some unit of time. Thus the rate of a ship's motion is determined when we say that it is nine miles in an hour, or nine miles per hour. We sometimes say (but awkwardly) "the motion is at the rate or with the velocity of a mile in three days." It is most conveniently expressed by a number of some given units of length, which completely make up the line described during this unit of time. But the mechanicians express it in a way more general by a fraction, of which the numerator is a number of inches, feet, yards, fathoms, or miles, and the denominator is the number of seconds, minutes, or hours employed in moving along this line. This is a very proper expression; for when we speak of any velocity, and continue to reason from it, we conceive ourselves to speak of something that remains the same, in the different occasions of using the term. Now if the velocity be constant, it is indifferent how long the line may be, because the time of its description will be lengthened in the same proportion. Thus if 48 feet be described in 12 seconds, 36 feet will be described in 9 seconds, 16 feet will be described in 4 seconds, &c. Now $\frac{48}{12}$, $\frac{36}{9}$, and $\frac{16}{4}$, are fractions of equal value, being equal to $\frac{4}{1}$, or 4, that is, to the velocity of 4 feet per second. The value of this fraction, or the quotient of the number of the units of length, divided by the number of units of time, is the number of those units of length described uniformly in one unit of time.

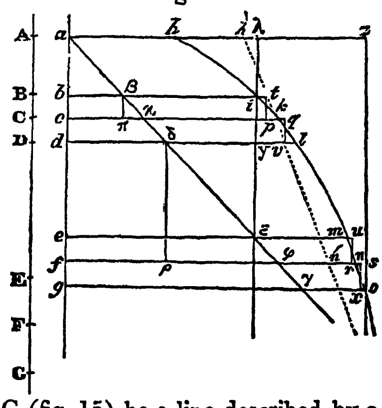
Magnitude of a velocity of which we

But how shall we determine the velocity in any instant or in any point of a motion that is continually changing? Suppose that a body has fallen 144 feet, and that we would ascertain its velocity in that point of its fall, or the velocity which it has in passing through that point. In the next second the body falls 112 feet farther. This cannot be the measure of the velocity at the beginning of the fourth or the end of the third second. It is too great. The fall during the preceding second was 80 feet. This is too small. The mean of these two, or $\frac{80+112}{2}, = \frac{192}{2} = 96$, is probably more exact. Due attention to the nature of this motion shows us that 96 is the proper measure, or that the motion at that instant is at the rate of 96 feet per second. But it is peculiar to this kind of motion that the half sum of the spaces described in two succeeding equal moments is the measure of the velocity in the middle instant. Therefore this method will not generally give an accurate measure. Yet it is indispensably necessary to obtain some accurate measure; for it is in this particular alone that the state of the body differs from its similar state in another instant. The difference of place makes no distinction; for if a body continue its motion unchanged, its condition in every different instant of time, or point of space, is unchanged, or the same. The change of place is not a change of motion, but is involved in the very conception of the continuation of the motion. The change of condition consists, therefore, in the change of velocity: therefore the change of velocity is the only indication and the only measure of the action (perhaps accumulated) of the changing force. It is therefore the chief object of our search; and accurate measures of velocity are absolutely necessary.

72. When the velocity changes continually, there can be no *actual* measure of it. In what then does the magnitude of a velocity consist, when there is no actual measure of it? It is a certain undescribable *determination*, by which, if not changed, a certain space *would* be uniformly described in a given unit of time. Thus we know, that if, when a stone has fallen sixteen feet, its motion be directed along a horizontal plane, without diminution, it will move on for ever at the rate of thirty-two feet per second. The space which would be thus described is not the velocity, but the measure of the velocity. But the proportions of those spaces, being the proportions of those measures, are the proportions of the velocities themselves. We may discover these proportions in the following manner.

Momentary proportion of velocities that are continually changing.

Fig. 15.



Fundamental requisite in all mechanical disquisitions.

Let ACG (fig. 15) be a line described by a body with a motion any how continually but gradually varied; and let it be required to determine the proportion of the velocity in any point C to the velocity in any other point F.

Axiom.—If A be to B in a ratio that is greater than any ratio less than that of C to D, but less than any ratio greater than that of C to D, then A is to B as C to D.

Take the straight line *acg* to represent the time of the body's motion along ACG, so that the points *a*, *c*, *f*, *g*, may represent the instants of time in which the body passes through the points A, C, F, G; and the portions *ac*, *cf*, *fg*, of the line *ag*, may represent the times employed in describing the portions AC, CF, FG; and therefore *ac* is to *af* as the time of describing AC to the time of describing AF.

Of Accelerated and Retarded Motions.

Moreover, let *hkno* be a line so related to the straight line *acfg*, by the perpendicular ordinates *ah*, *ck*, *fn*, *go*, that the areas *ackh*, *afnh*, *agoh*, may be proportional to the portions AC, AF, AG, of the line described by the moving body; and let this relation be true with respect to every point B, D, E, &c. and the corresponding points *b*, *d*, *e*, &c.

Then it is affirmed that *the velocity in the point* C *is to the velocity in the point* F *as ck is to fn.*

Let the equal lines *bc*, *cd*, *ef*, *fg*, represent equal moments of time, and let B, D, E, G, be the points through which the body is passing at the instants *b*, *d*, *e*, *g*. Then the areas *bikc*, *ckld*, *emnf*, *fnog*, will represent, and be proportional to, the spaces BC, CD, EF, FG, which are described during the moments *bc*, *cd*, *ef*, *fg*.

Draw *tp* parallel to *ag*, so as to make the rectangle *btpc* equal to the trapezium *bikc;* and draw the lines *qv*, *ur*, *sx*, in the same manner, so that each rectangle may be equal to its corresponding trapezium.

If the motions had been uniform during the moments *bc* and *fg*, that is, if the spaces BC and FG had been uniformly described, then the velocity in the point C would have been to the velocity in the point F as *cp* to *fs;* for since the rectangles *btpc* and *fsxg* are respectively equal to the trapeziums *bikc* and *fnog*, and since *bikc* is to *fnog* as BC is to FG, the rectangle *btpc* is to the rectangle *fsxg* as BC to FG. But because these two rectangles have equal altitudes *bc* and *fg*, they are to each other in the proportion of their bases *cp* and *gx*, or *cp* and *fs*. Therefore BC is to FG as *cp* to *fs*. But if BC and FG are uniformly described in equal times, they are proportional to the velocities of those uniform motions. Therefore *cp* is to *fs* as the velocity with which BC is uniformly described to the velocity with which FG is uniformly described in an equal time.

But the motion expressed by the figure is not uniform, because the line *hlo* recedes from the axis *ag*, and the areas, cut off by the parallel ordinates, increase in a greater proportion than the corresponding parts of the axis; that is, the spaces increase faster than the times; for the moments *bc*, *cd*, *ef*, *fg*, being all equal, it is evident that the corresponding slips of the area continually augment. The motion is swifter at the instant *c* than at the instant *b*, and the velocity at the instant *c* is *greater* than that with which the space BC would be uniformly described in the same time. For the same reason, the velocity at the instant *f* is *less* than that with which the space FG would be uniformly described in the same time. Therefore the velocity at the instant *c* is to the velocity at the instant *f* in a greater ratio than that of *cp* to *fs*. In the very same manner, it will appear, by comparing the motion during the moment *cd* with the motion during the moment *ef*, that the velocity at the instant *c* is to the velocity at the instant *f* in a less ratio than that of *cq* to *fr*.

Therefore the velocity in the point C is to the velocity in the point F in a greater ratio than that of *cp* to *fs*, but in a less ratio than that of *cq* to *fr*.

But by continually diminishing the equal moments *bc*, *cd*, *ef*, *fg*, it is evident that *cp* and *cq* continually approach to equality with *ck*, and *fr* and *fs* continually approach to equality with *fn;* that when *cp* is less than *ck*, *fs* is greater than *fn*, and when *cq* is greater than *ck*, *fr* is less than *fn*.

Therefore the velocity in the point C is to the velocity in the point F in a ratio that is greater than the ratio of *any* line less than *ck* to *any* line greater than *fn*, but which is less than the ratio of any line greater than *ck* to any line less than *fn*. Therefore the ratio of the velocity in C to the velocity in F is greater than any ratio that is less than that of *ck* to *fn;* but it is less than any ratio that is greater than that of *ck* to *fn*. Therefore the velocity in the point C is to the velocity in the point F as *ck* to *fn*.

This important theorem may be expressed in more general terms as follows:

If the abscissa ag of a line hko represent the time of any motion, and if the areas bounded by parallel ordinates be proportional to the spaces described, the ordinates are proportional to the velocities.

Remark.—The propriety or aptitude of expressing the time by the portions of the axis *acg* will perhaps appear more clearly in the following manner:

Let *acg* be any straight line, and let *h'kv* be another line straight or curved. Let the straight line *ahz*, perpendicular to *ag*, be carried uniformly down along this line, keeping always perpendicular to it, and therefore always parallel to its first position *ahz*. In its various situations *ckz*, *emz*, &c. it will cut off areas *ackh*, *aemh*, &c. bounded by the axis, by the ordinates *ah* and *ck*, or by the ordinates *ah* and *em*, &c. and by the line *hkg*. By this motion the moveable ordinate is said, in the language of modern geometry, to *generate* the areas *ackh*, *aemh*, &c. At the same time, let a point A move along the line ACG, setting out from A at the instant when the line *az* sets out from *a;* and let the motion of the point A be so regulated that the spaces AB, AC, AD, &c. generated by this motion may increase at the same rate with the areas *abih*, *ackh*, *adlh*, &c. or such that we shall have AB to AC as *abih* to *ackh*, &c. It is plain that the motion along AG is the same with that described in the enunciation of the proposition; for because the motion of the ordinate *az* along the axis *ag* is supposed to be uniform, the spaces *ab*, *ac*, *ad*, &c. are proportional to the times in which they are described, and may therefore be taken to measure or to represent those times.

73. Cor. 1. *In a motion continually varied, the velocities in the different points of the path are to each other in the limiting or ultimate ratio of the spaces described in equal times,* those times being supposed to diminish continually; for it is evident that if the equal moments *bc*, *cd*, *ef*, *fg*, are supposed to diminish continually till the instants *b* and *d* coalesce with *c*, and the instants *e* and *g* coalesce with *f*, then the ratio of *ck* to *fn* is the limit of the continually increasing ratio of *cp* to *fs*, or of the continually diminishing ratio of *cq* to *fr*. Sir Isaac Newton calls this the ultimate ratio of *cp* to *fs*, or of *cq* to *fr*. Now the ratio of *cp* to *fs* is, by construction, the same with the ratio of the rectangle *btpc* to the rectangle *fsxg*, and the ratio of *cq* to *fr* is the same with the ratio of the rectangle *cqvd* to the rectangle *eurf*. But the ratio of the rectangle *btpc* to the rectangle *fsxg* is the same with the ratio of the space *bikc* to the space *fnog;* that is (by hypothesis) the same with the ratio of the space BC to the space FG; and the ratio of the rectangles *cqvd* and *eurf* is the same with that of the spaces CD and EF. Therefore the ratio of the velocity at C to the velocity at F is the same with the ultimate ratio of the small increments BC, FG, or CD, EF of the spaces generated in very small and equal times.

It is also evident, that because the ratio of *ck* to *fn* is the limit both of the ratio of *cp* to *fs* and of the ratio of *cq* to *fr*, these ultimate ratios are the same, and that we may say that the velocity in C is to the velocity in F in the ultimate ratio of BC to EF, or in the ultimate ratio of CD to FG.

We also can easily perceive that the ratio of the area *bikc* to the area *emnf* approaches more near to the ratio of *ck* to *fn* as we take the moments *bc* and *ef* smaller. Therefore, in many cases of practice, where it may be easy to measure the spaces described in the different small moments of the motion, but difficult to ascertain their ultimate ratio, so as to obtain accurate measures of

Of Accelerated and Retarded Motions.

the proportions of the velocities, we may reduce the errors of measurement to something very insignificant, by taking these moments extremely small; and we shall diminish the error still more by taking the proportion of the half sum of BC and CD to the half sum of EF and FG for the proportion of the velocities in C and F.

It often happens that we have it not in our power to compare the spaces described in small moments which are precisely equal. Still we can find the exact proportion of the velocities, if we can ascertain the ultimate ratio of the increments of the spaces, and the ultimate ratio of the moments of time in which these increments are described; for it is plain, by considering the gradual approach of the points p and r to the points k and n, that the ratio of ck to fn is still the ultimate ratio of the bases of rectangles equal to the mixtilineal areas, whether the altitudes (representing the moments) are equal or not. Now the bases of two rectangles are in the proportion of the rectangles directly, and of their altitudes inversely. But the ultimate ratio of the altitudes is the ultimate ratio of the moments, and the ultimate ratio of the rectangles is the ultimate ratio of the spaces described in those unequal moments. Therefore, in such cases, we have,

74. Cor. 2. *The velocities are in the ratio compounded of the direct ultimate ratio of the momentary increments of the spaces, and the inverse ultimate ratio of the increments (or moments) of the times in which these increments of the spaces are made.*

If s, v, and t, are taken to represent the magnitudes of the spaces, velocities, and times, and if ds, dt, and dv, are taken always in the limiting or ultimate ratio of their momentary increments,[1] we shall have v always in the proportion of ds directly, and of dt inversely. We express this by the proportional equation $v \doteqdot \frac{ds}{dt}$, which is equivalent to the analogy $V : v = \frac{dS}{dT} : \frac{ds}{dt}$, or $V : v = dSdt : dsdT$.

75. N. B. Here observe that this is not the only way of stating the relation of space and time—the abscissa may be made the time, and the ordinate the space: then the velocity $= \frac{dy}{dx}$.

The converse of this proposition may be thus expressed.

Converse theorem.

76. *If the axis ag of the line hko represent the time of a varied motion along the line* AG, *and if the ordinates ah, bi, ck, &c. be as the velocities in the instants a, b, c, or in the points* A, B, C; *then the areas abih, ackh, adlh, &c. are proportional to the spaces* AB, AC, AD, &c.

This may be demonstrated in the same way with the former; but the indirect demonstration is more brief, and equally strict.

If the spaces AC, AF, &c. are not proportional to the areas *ackh*, *afnh*, &c. they are proportional to some other areas *ackh'*, *afn'h'*, &c. which are bounded by the same ordinates, and by another line *h'kn'*. But because the areas *ackh'*, *afn'h'*, &c. are always proportional to the spaces AC, AF, &c. described on the line AG, the velocity in the point C is to the velocity in the point F as the ordinate *ck* is to the ordinate *fn'*; but, by hypothesis, the velocity in C is to the velocity in F as *ck* to *fn*, and *fn'* is equal to *fn*, which is absurd. Therefore the spaces AC, AF, are not proportional to any other areas, &c.

77. Cor. *The ultimate ratio of the momentary increments of the spaces is compounded of the ratio of the velocities, and the ultimate ratio of the increments of the times:* for when the moments *bc*, *ef*, are equal, it is evident that the ultimate ratio of the rectangles *bcpt*, *efru* is the same with the ultimate ratio of the increments of the spaces. But the ultimate ratio of these rectangles is the same with that of their bases *cp* and *fr*; that is, the ratio of *ck* to *fn*, that is, the ratio of the velocities. And when the moments are unequal, the ratio of the rectangles is compounded of the ratio of their bases and the ratio of their altitudes; that is, compounded of the ratio of the velocities and the ultimate ratios of the moments of time.

We have therefore $dS : ds = VdT : vdt$ and $ds \doteqdot vdt$.

It most commonly happens that we can only observe the accumulated results of varied motions, and in them we only observe a space passed over, and a certain portion of time that has elapsed during the motion; but being able to distinguish the portions of the whole space which are described in known portions of the whole time, and having made such observations in several parts of the motion, we discover the general law that the motion affects, and we affirm this law to hold universally, even though we have not observed it in *every* point. We do this with a degree of probability and confidence proportioned to the frequency of our observation. It is not till we have done this that we can make use of the first of these two propositions, which enables us to ascertain the velocity of the motion in its different moments. Thus, if we observe that a stone in falling descends one foot in the quarter of a second, 16 feet in a second, 64 feet in two seconds, and 144 feet in three seconds, the general law immediately observed is, "that the spaces described are as the squares of the times;" for 1 is to 16 as the square of $\frac{1}{4}$ to the square of 1. Again, 16 is to 64 as 1^2 to 2^2, and 16 is to 144 as 1^2 to 3^2. Hence we infer, with great probability, that the stone would fall 36 feet in a second and a half; for 16 is to 36 as 1^2 to $1\frac{1}{2}^2$; and we conclude in the same way for all other parts of the motion.

A good example of geometrical method.

78. This immediate observation of the analogy between the spaces and the squares of the times suggests an easy determination of the velocity in this particular kind of motion, and it merits particular notice, being very often referred to. We can take *ag* to represent the time, and then, because the areas which are to represent the spaces described must be proportioned to the squares of the portions of *ag*, we perceive that the line which comes in place of *hko* must be a straight line drawn from *a*; for example, the straight line $a\delta\gamma$; for this is the only boundary which will give areas $ab\beta$, $ac\varkappa$, $ad\delta$, &c. proportional to ab^2, ac^2, ad^2, &c. And we perceive that *any* straight line drawn from *a* will have this property.

Having thus got our representations of the times and the spaces, we say, on the authority of our theorem, that the velocity at the instant *b* is to the velocity at the instant *d* as $b\beta$ to $d\delta$, &c. And now we begin to make inferences purely geometrical, and express our discovery of the velocities in a very general and simple manner. We remark, that $b\beta$ is to $d\delta$ as *ab* is to *ad*; and we make the same affirmation concerning the magnitudes represented by these lines. We say that the velocity at the instant *b* is to the velocity at the instant *d* as the time *ab* is to the time *ad*. We say, in terms still more general, that the velocities are proportional to the times from the beginning of the motion. We moreover perceive, that the spaces are

[1] In this article, as originally printed, the symbols $\dot{s}$, $\dot{t}$, and $\dot{v}$ were employed to represent the things here denoted by ds, dt, and dv: a like change in the notation of the fluxions of the quantities will be made throughout the article

Of Accelerating and Retarding Forces.

also proportional to the squares of the acquired velocities; or the velocities are as the square roots of the spaces.

We can further infer, from the properties of the triangle, that the momentary increments of the spaces are proportional to the momentary increments of the squares of the times, or of the squares of the velocities.

We also observe, that not only the whole acquired velocities are proportional to the whole elapsed times, but that the increments of the velocities are proportional to the times in which they are acquired; for $\pi\kappa$ is to $\rho\phi$ as bc to df, &c. Equal increments of velocity are therefore acquired in equal times. Therefore such a motion may, in great propriety of language, be denominated a *uniformly accelerated motion;* that is, *a motion in which we observe the spaces proportioned to the squares of the times, is a motion uniformly accelerated;* and spaces in the duplicate ratio of the times form the ostensible characteristic of an uniformly accelerated motion.

79. Lastly, if we draw $\iota\lambda$ parallel to the axis ab, we perceive that the rectangle $ae\iota\lambda$ is double of the triangle $ae\iota$. Now, because ae represents the time of the motion, and $e\iota$ represents the acquired velocity, the rectangle $ae\iota\lambda$ will represent the space which would be uniformly described with the velocity $e\iota$ during the time ae. But the triangle $ae\iota$ represents the space really described with the uniformly accelerated motion during the same time. Hence we infer, that the space that is described in any time, with a motion increasing uniformly from nothing, is one half of the space which would be uniformly described during the same time with the final velocity.

These are but a part of the inferences which we may draw from the geometrical properties of those representations which we had selected of the different measureable affections of motion. We may affirm, with respect to the motions themselves, all the inferences which relate to magnitude and proportion, and thus improve our knowledge of the motions.

We took the opportunity of this very simple and perspicuous example, to give our readers a just conception of the *mathematical method* of prosecuting mechanical knowledge, and to make them sensible of the unquestionable authority for every theorem deduced in this manner.

One of the most important is, to discover the accumulated result of a motion of which we only observe the momentary increments. This is to be done by finding the area, or portions of the area, of the mixtilineal space *agoh;* and it is evidently analogous to the inverse method of fluxions, or the integral calculus.

In most cases, we must avail ourselves of the corollary $ds \doteq vdt$, and we obtain the solution of our question only in the cases where our knowledge of the quantities ds, dt, and v (considered as geometrical magnitudes, that is, as lines and surfaces), enables us to discover s and t.

OF ACCELERATING AND RETARDING FORCES.

80. Having thus discovered the proportions of the velocities in motions varying in any manner whatever, we can observe the variations which happen in them. These variations are the effects, and the only marks and measures, of the changing forces. They are the characteristics of their kinds (considered merely as moving forces); that is, the indications of the directions in which they act; for this is the only difference *in kind* of which they are susceptible in this general point of view. If they increase the velocity, their direction must be conceived as the same with that of the previous motion; because the result of the action of a force is equivalent to the composition of the motion which that force would produce in a quiescent body with the motion already existing; and an increase of velocity is equivalent to the composition of a motion in the same direction.

Of Accelerating and Retarding Forces.

Having no other mark of the force but the acceleration, we have no other name for it in the abstract doctrines of dynamics, and we call it an *accelerating force.* Had it retarded the motion, we should have called it a *retarding force.*

In like manner we have no measure of the *magnitude* or *intensity* of an accelerating force, but the acceleration which it produces. In order therefore to investigate the powers which produce all the changes of motion, we must endeavour to obtain measures of the acceleration.

A continual increase of velocity is the effect of the continued action of accelerating forces. If equal increments of velocity are produced in every succeeding equal moment of time, we cannot conceive that there is any change in the accelerating force. Therefore a uniformly accelerated motion is the mark of the unvaried action of an accelerating force, that is, of the continued action of a constant force; of a force whose intensity is always the same. When therefore we observe a body describe spaces proportional to the squares of the times, we must infer that it is urged forward by a force whose intensity does not change; and, on the other hand, a constant force must produce a uniformly accelerated motion by its continued action. And if any previous circumstances assure us of this continued action of an invaried force, we may make all the inferences which were mentioned under the article of uniformly accelerated motion.

Measure of an accelerating force.

81. That force must surely be accounted double which produces a double increment of velocity in the same time by its uniform action; we can form no other estimation of its magnitude. And in general, *accelerating forces must be accounted proportional to the increments of velocity which they produce, by acting uniformly during the same or equal times.*

Supposing them to act on a body at rest. Then the velocity produced is itself the increment; and we must say that accelerating forces are proportional to the velocities which they generate in a body in equal times. And because we found (No. 79), that the space described with a uniformly accelerated motion is half the space which would be uniformly described in the same time with the final velocity, which space is the direct measure of this velocity, and because halves have the same proportion with the wholes—we may say that *accelerating forces are proportional to the spaces through which they impel a body from rest in equal times by their uniform action.*

Another measure.

This is an important remark; because it gives us an easy measure of the force, without the trouble of first computing the velocities. It also gives us the only distinct notion that we have of the measurement of forces by the motions which they produce. When speaking of the composition of forces, we distinguished or denominated them by the sides and diagonal of a parallelogram. These lines must be conceived as proportional to the spaces through which the forces urge the body *uniformly* during the small and insensible time of their action, which time is supposed to be the same for both forces; for the sides of the parallelogram are supposed to be separately described in equal times, and therefore to be proportional to the velocities generated by the constituent forces. If indeed the forces do not act uniformly, nor similarly, nor during equal times, we cannot say (without farther investigation) what is the proportion of the intensity of the forces, nor can we infer the composition of their action. We must at least suppose, that in every instant of this very small time of their joint action, their direction remains unchanged, and that their intensities are in the

same ratio. We shall see by and by, that with these conditions the sides of the parallelogram are still proportional to the velocities generated. In the mean time we may take the spaces through which a body is uniformly impelled from rest (that is, with a uniformly accelerated motion) as the measures of the forces; yet these spaces are but the halves of the measures of the velocities. Then, if a body be moving with the velocity of thirty-two feet per second, and an accelerating force acts on it during a second, and if this force be such that it would impel the body (from a state of rest) sixteen feet, it will add to the body a velocity of thirty-two feet per second. Accordingly, this is the effect of gravity—the weight of a pound of lead may be considered as a force which does not vary in its intensity. We know that it will cause the lead to fall sixteen feet in a second; but if the body has already fallen sixteen feet, we know that it is then moving with the velocity of thirty-two feet per second. And the fact is, that it will fall forty-eight feet farther in the next second, and will have acquired the velocity of sixty-four feet per second. It has therefore received an augmentation of thirty-two feet of velocity by the action of gravity during the second second; and gravity is in fact a constant force, causing equal increments of velocity in equal times, however great the velocities may be. It does not act like a stream of fluid, whose impulse or action diminishes as the solid body withdraws from it by yielding.

But supposing that we have not compared the increments of velocity uniformly acquired during equal times, in what manner shall we measure the accelerating forces? In such a case that force must be accounted double which generates the same velocity, by acting uniformly during half the time; for when the force is supposed invariable, the changes of velocity which it produces are proportional to the times of its action; therefore if it produces an equal velocity in half the time, it will produce a double velocity in an equal time, and is therefore a double force. The same may be said of every proportion of time in which an equal change of velocity is produced by the uniform action of an accelerating force. The force must be accounted greater in the same proportion that the time required for the production of a given velocity in a body is less. Hence we infer that *accelerating forces are inversely proportional to the times in which a given change of velocity is produced by their uniform action.*

82. By combining these two propositions, we establish this general theorem:

Measure of accelerating force.

Accelerating forces are proportional to the changes of velocity which they produce in a body by their uniform action directly, and to the times in which these changes are produced inversely.

If, therefore, A and a are the forces, V′ and v' the changes of velocity, and T′ and t' the portions of time in which they are uniformly produced, we have

$$\mathrm{A} : a = \mathrm{V}'t' : v'\mathrm{T}', = \frac{\mathrm{V}'}{\mathrm{T}'} : \frac{v'}{t'}$$

$$\text{and } a \doteqdot \frac{v'}{t'}.$$

The formula $a \doteqdot \dfrac{v'}{t'}$ is not restricted to any particular magnitude of v' and t'. It is true, therefore, when the portion of time is diminished without end; for since the action is supposed uniform, the increment of velocity is lessened in the same proportion, and the value of the fraction $\dfrac{v'}{t'}$ remains the same. The characters or symbols v' and t' are commonly used to express *finite* portions of v and t. The symbols $\dot{v}$ and $\dot{t}$ are used by Newton to express the same things taken in the ultimate or limiting ratio. (These have been changed to dv and dt throughout this article.) They are usually considered as *indefinitely small* portions of v and t. We shall abide by the formula $a \doteqdot \dfrac{dv}{dt}$.

83. It must always be kept in mind, that v and t are abstract numbers; and that v refers to some unit of space, such as a foot, an inch, a yard; and that t refers to some unit of time, such as an hour, a minute, a second; and especially that a is the number of the same units of space, which will be uniformly described in *one* unit of the time with the velocity generated, by the force acting uniformly during *that* unit. It is twice the space actually described by the body during that unit when impelled from rest by the accelerating force. It is necessary to keep hold of these clear ideas of the quantities expressed by the symbols.

Is an abstract number.

On the other hand, when the measure of the accelerating force is previously known, we employ the theorem $at = v'$; that is, the addition made to the velocity during the whole or any part of the time of the action of the force is obtained by multiplying the acceleration of one unit of time by the number of such units contained in t'.

Measure of a change of velocity.

These are evidently leading theorems in dynamics, because all the mechanical powers of nature come under the predicament of accelerating or retarding forces. It is the collection of these in any subject, and the manner in which they accompany or are inherent in it, which determine the mechanical character of that subject; and therefore the phenomena by which they are brought into view are the characteristic phenomena. Nay, it may even be questioned whether the phenomena bring any thing more into view. This force, of which we speak so familiarly, is no object of distinct contemplation; it is merely a something that is proportional to $\dfrac{dv}{dt}$. And when we observe that the $\dfrac{d\mathrm{V}}{d\mathrm{T}}$, found in the motions that result from the vicinity of a body A, is double of the $\dfrac{dv}{dt}$ which results from the vicinity of another body B, we say that a force resides in A, and that it is double of the force residing in B. The accelerations are the things immediately and truly expressed by these symbols. And the whole science of dynamics may be completely taught without once employing the word *force*, or the conception which we imagine that we form of it. It is of no use till we come to study the mechanical history of bodies. Then, indeed, we must have some way of expressing the fact, that an acceleration $= \dfrac{32 \text{ feet}}{1''}$ is observed in every thing on the surface of this globe; and that an acceleration $= \dfrac{418 \text{ feet}}{1''}$ is observed over all the surface of the sun. These facts are characteristic of this earth and of the sun; and we express them shortly by saying that such and such forces reside in the earth and in the sun. It will preserve us from many mistakes and puzzling doubts, if we resolutely adhere to this meaning of the term *force;* and this will carry mathematical evidence through the whole of our investigations.

These measures express the greatest part of our knowledge of mechanical nature.

84. As velocity is not an immediate object of contemplation, and all that we observe of motion is a space and a time, it may be proper to give an expression of this measure of accelerating force which involves no other idea. Supposing the body to have been previously at rest, we

Another measure of accelerating force.

Of Accelerating and Retarding Forces.

have $a \doteqdot \frac{v}{t}$. Multiply both parts of the fraction by t which does not change its value, and we have $a \doteqdot \frac{vt}{t^2}$.

But $vt = s$; and therefore $a \doteqdot \frac{s}{t^2}$.

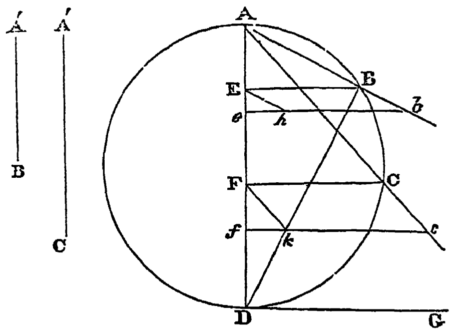
The formula $a = \frac{s}{t^2}$ is equivalent to the proportion $t^2 : 1 = s : a$; and a would then be the space through which the accelerating force would impel the body in one unit of the time t. But this is only half of the measure of the velocity which the accelerating force generates during that unit of time. For this reason we did not express the accelerating force by an ordinary equation, but used the symbol $\doteqdot$. In this case, therefore, of uniform action, we may express the accelerating force by $a = \frac{2s}{t^2}$.

85. The following theorem is of still more extensive use in all dynamical disquisitions.

Most general measure of accelerating force.

Accelerating forces are proportional to the momentary increments of the squares of the velocities directly, and as the spaces along which they are uniformly acquired inversely.

Fig. 16.



Let A′B, A′C, and AD (fig. 16) be three lines, described in the same or equal times by the uniform action of accelerating forces; the motions along these lines will be uniformly accelerated, and the lines themselves will be proportional to the forces, and may be employed as their measures. On the greatest of them, AD, describe the semicircle ABCD, and apply the other two lines A′B, A′C as chords AB, AC. Draw EB, FC perpendicular to AD. Take any small portions Bb, Cc of AB and AC, and draw be, cf perpendicular to AD, and Eh and Fk parallel to AB and AC.

Then, because the triangles DAB and BAE are similar, we have $AD : AE = AD^2 : AB^2$. And because AD is to AB as the velocity generated at D is to the velocity generated at B (the times being equal), we have AD to AE as the square of the velocity at D to the square of the velocity at B; which we may express thus:

$$AD : AE = V^2, D : V^2, B.$$

For the same reasons we have also

$$AD : AF = V^2, D : V^2, C. \quad \text{Therefore}$$
$$AE : AF = V^2, B : V^2, C.$$

But because in any uniformly accelerated motion, the spaces are as the squares of the acquired velocities, we have also

$$AE : Ae = V^2, B : V^2 b, \text{ and}$$
$$AF : Af = V^2, C : V^2 c.$$

Therefore Ee is to Ff as the increment of the square of the velocity acquired in the motion along Bb to the increment of the square of the velocity acquired along Cc.

But by similarity of the triangles ABD and Eeh, we have

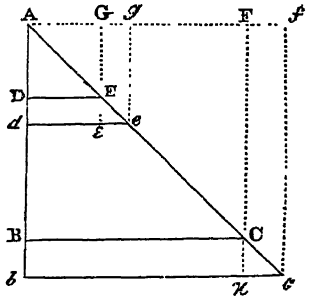
$$AB : AD = Ee : Eh; \text{ and in like manner,}$$
$$AD : AC = Fk : Ff. \quad \text{Therefore}$$
$$AB : AC = Ee \times Fk : Ff \times Eh.$$

Now AB and AC are proportional to the forces which accelerate the body along the lines A′B and A′C; Ee and Ff are proportional to the increments of the squares of the velocities acquired in the motions along the portions Bb and Cc; and Eh and Fk are equal to those portions respectively. The ratio of AB to AC is compounded of the direct ratio of Ee to Ff, and the inverse ratio of Eh to Fk. The proposition is therefore demonstrated.

The proportion may be expressed thus:

$AB : AC = \frac{Ee}{Eh} : \frac{Ff}{Fk}$, and may be expressed by the proportional equation $AB \doteqdot \frac{Ee}{Eh}$, or symbolically, $a \doteqdot \frac{d(v^2)}{ds}$.

Fig. 17.



vdv is but one half of the increment of v^2

REMARK.—Because the motion along any of these three lines is uniformly accelerated, the relation between spaces, times, and velocities, may be represented by means of the triangle ABC (fig. 17); where AB represents the time, BC the velocity, and ABC the space. If BC be taken equal to AB, the triangle is half of the square ABCF of the velocity BC; and the triangle ADE is half of the square ADEG of the velocity DE. Let Dd and Bb be two moments of time, equal or unequal. Then DdeE and BbcC are half the increments of the squares of the velocities DE and BC, acquired during the moments Dd and Bb. It was demonstrated that the ratio of the area DdeE to the area BbcC is compounded of the ratio of DE to BC, and the ultimate ratio of Dd to Bb. But Dd and Bb are respectively equal to εe and $\varkappa c$. Therefore DdeE is to BbcC, in the ratio compounded of the ratio of DE to BC, and the ultimate ratio of εe to $\varkappa c$. If we represent DE and BC by V and v, then εe and $\varkappa c$ must be represented by V′ and v', the increments of V and v; and then the compound ratio will be the ratio of VV′ to vv'; and if we take the ultimate ratio of the moments, and consequently the ultimate ratio of the increments of the velocities, we have the ratio of VdV to vdv. If therefore V^2 and v^2 represent the squares of the velocities, VdV and vdv will represent, not the increments of those squares, but half the increments of them.

We may now represent this proposition concerning accelerating forces by the proportional equation $a \doteqdot \frac{vdv}{ds}$;

and we must consider this as equivalent with $a = \frac{V^2 - v^2}{2(S - s)}$;

keeping always in mind that a, V, and v, relate to the same units of time and space, and that a is that number of units of the scale on which S and s are measured, which is run over in *one* unit of time.

Of Accelerating and Retarding Forces.

This will be more clearly conceived by taking an example. Let us ascertain the accelerative power of gravity, supposing it to act uniformly on a body. Let the spaces be measured in feet and the time in seconds. It is

Measure of gravity considered as an accelerating force.

a matter of observation, that when a body has fallen 64 feet, it has acquired a velocity of 64 feet per second; and that when it has fallen 144 feet, it has acquired the velocity of 96 feet per second. We want to determine what velocity gravity communicated to it by acting on it during one second. We have $V^2 = 9216$, and $v^2 = 4096$; and therefore $V^2 - v^2 = 5120$. $S = 144$, and $s = 64$, and $S - s = 80$, and $2(S - s) = 160$. Now $a = \frac{5120}{160}, = 32$. Therefore gravity has generated the velocity 32 feet per second by acting uniformly during one second.

86. *The augmentation of the square of the velocity is proportional to the force and to the space jointly.* For, because $a = \frac{vdv}{ds}$, we have $ads = vdv$.

Thus we learn, that a given force, acting uniformly on a body along a given space, produces the same increment of the square of the velocity, whatever the previous velocity may have been. Also, in the same manner as we formerly found that the augmentation of the velocity was proportioned to the time during which the force has acted, so the augmentation of the square of the velocity is proportional to the space along which it has acted.

Theorems respecting retarding forces.

It is pretty plain, that all that we have said of the uniform action of an *accelerating* force may be affirmed of a *retarding* force, taking a diminution or decrement of velocity in place of an increment. A uniformly retarded motion is that in which the decrements of velocity in equal terms are equal, and the whole decrements are proportional to the whole times of action. Such a motion is the indication of a constant or invariable force acting in a direction opposite to that of the motion. We conceive this to be the case, when an arrow is shot perpendicularly upwards; its weight is conceived as a force continually pressing it perpendicularly downwards.

In such motions, however great the initial velocity may be, the body will come to rest; because a certain determined velocity will be taken from the body in each equal successive moment, and some multiple of this will exceed the initial velocity. Therefore the velocity will be extinguished before the end of a time that is the same multiple of the time in which the velocity was diminished by the quantity above mentioned. It is no less evident that the time in which any velocity will be extinguished by an opposing or retarding force, is equal to the time in which the same force would generate this velocity in the body previously at rest. Therefore,

87. (1.) The times in which different initial velocities will be extinguished by the same opposing force are proportional to the initial velocities.

88. (2.) The distances to which the body will go till the extinction of its velocity, are as the squares of the initial velocities.

(3.) They are also as the squares of the times elapsed.

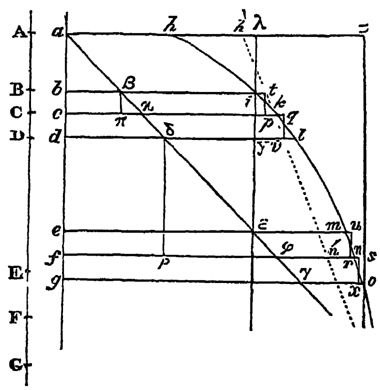
89. (4.) The distance to which a body, projected with any velocity, will go till its motion be extinguished by the uniform action of a retarding force, is one half of the space which it would describe uniformly during the same time with the initial velocity.

Forces generally variable in their intensity.

It very rarely happens that the force which accelerates the body acts uniformly, or with an unvaried intensity. The attraction of a magnet, for example, increases as the iron approaches it. The pressure of a spring diminishes as it unbends. The impulse of a stream of water or wind diminishes as the impelled surface retires from it by yielding. Therefore the effects of accelerating forces are very imperfectly explained, till we have shown what motions result from any given variation of force, and how to discover the variation of force from the observed motion. This last question is perhaps the most important in the study of mechanical nature. It is only thus that we learn what is usually called *the nature of a mechanical force.* This chiefly consists in the relation subsisting between the intensity of the force and the distance of the substance in which it resides. Thus the nature of that power which produces all the planetary motions, is considered as ascertained, when we have demonstrated that its pressure or intensity is inversely as the square of the distance from the body in which it is supposed to reside.

Acceleration expresses some relation of the velocity and time. This relation may be geometrically expressed in a variety of ways. In fig. 18 the uniform acceleration, or the unvaried relation between the velocity and the time, is very aptly expressed by the constant ratio of the ordinates and abscisses of the triangle *agv*. The ratio of $d\delta$ to *ad* is the same with that of $e\varepsilon$ to *ae*, or that of $f\varphi$ to *af*, &c.; or the ratio of the increment of velocity $\pi\varkappa$ to the increment of the time $\beta\pi$ or *bc*, or that of $\iota\varphi$ to $\varepsilon\iota$, &c. This ratio $\pi\varkappa : \beta\pi$ is equivalent to the symbol $\frac{dv}{dt}$.

Fig. 18.



But when the spaces described in a varied motion are represented by the areas bounded by a curve line *hko*, we no longer have that constant ratio of the increments of the ordinates and abscisses.

Their measures in such cases how obtained. Theorems of most extensive use.

90. Therefore, in order to obtain measures of the accelerating forces, or at least of their proportions, let the abscissa *aeg* (fig. 18) of the line *hko* again represent the time of a motion. But let the areas bounded by parallel ordinates now represent the velocities; that is, let the whole area increase during the time *ag* at the same rate with the velocities of the motion along the line AG. In this case the ordinates *bi*, *ck*, *dl*, &c. will be as the accelerations at the instants *b*, *c*, *d*, &c. or in the points B, C, D, &c.

This is demonstrated in the same way as the former proposition (No. 72). If the accelerating force be supposed constant during any two equal moments *bc* and *fg*, the rectangles *bcpt* and *fgxs* would express the increments of velocity uniformly acquired in equal times, and their bases *cp* and *fs* would have the ratio of the accelerations, or of the accelerating forces. But as the velocities expressed by the figure increase faster than the times during every moment, the force at the instant *c* is to the force at the instant *f* in a greater ratio than that of *cp* to *fs*; but, for similar reasons, it is in a less ratio than that of *cq* to *fr*; and therefore (as in the other proposition) the force at the instant *c* is to the force at the instant *f* as *ck* to *fn*.

91. *Cor.* Because *cp* is to *fs* in the ratio compounded of

Of Accelerating and Retarding Forces.

the direct ratio of the rectangle *cptb* to the rectangle *fsxg*, and the inverse ratio of the altitude *bc* to the altitude *fg*; and because these rectangles are proportional to the increments of velocity, and the ultimate ratio of the altitudes is the ultimate ratio of the moments or increments of the time, we must say that *the accelerating forces (that is, their intensities or pressures producing acceleration) are directly as the increments of velocity, and inversely as the increments of the times;* which proposition may be expressed in regard to two accelerations A and a, by this analogy:—

$$A : a = \frac{dV}{dT} : \frac{dv}{dt}.$$

Or by the proportional equation $a \doteq \frac{dv}{dt}$. Also $adt \doteq dv$, and $\int adt = v'$. And thus do these theorems extend even to the cases where there cannot be observed an immediate measure either of velocity or of acceleration, because neither the space nor the velocity increases uniformly.

The theorem $a \doteq \frac{dv}{dt}$ is employed when we would discover the variation in the intensity of some natural power.[1] We observe the motion, and represent it by a figure analogous to fig. 18, where the abscissa represents the times, and the area is made to increase at the same rate with the spaces described. Then the ordinates will represent the velocities, or have the proportion of the velocities. Then we may draw a second curve on the other side of the same abscissa, such that the areas of this last curve shall be proportional to the ordinates of the first. The ordinates of this last curve are proportional to the accelerating forces.

92. On the other hand, when we know from other circumstances that a force, varying according to some known law, acts on a body, we can determine its motion. The intensity of the force in every instant being known, we can draw a line so related to another line representing the time, that the ordinates shall be proportional to the forces. The areas will be proportional to the velocities. We can draw another curve to the same absciss, such that the ordinates of this shall be proportional to the areas of the other, that is, to the velocities of the motion. The areas of this second curve will be proportional to the spaces described.

All these theorems relate to *changes* of velocity; by which means they indicate *immediately* the operation of natural powers.

93. We must now observe, that all that has been said concerning the effects of accelerating forces continually varying, relates to *changes* of motion, independent of what the absolute motions may be. The areas of the line whose ordinates represent the velocities do not necessarily represent the spaces described, but the change made on the spaces described in the same time; not the motions, but the changes of motion. If, indeed, the body be supposed to be at rest when the forces begin to act, these areas represent the very spaces that are passed over, and the ordinates are the very velocities. In every case, however, the accelerations are the real increments of the velocities.

This circumstance gives a great extension to our theorems, and enables us to ascertain the disturbances of any species of regular motion, apart from the motions themselves, and thus avoid a complication which would frequently be inextricable in any other way. And this process, which is merely mathematical, is perfectly conformable to mechanical principles. It is in fact an application of the doctrine of the composition of motion; a doctrine rigidly demonstrated when we measure a mechanical force by the *change* of motion which it produces. Acceleration is the continual composition of a new motion with the motion already produced.

No finite change of velocity can be produced in an instant by any accelerating force.

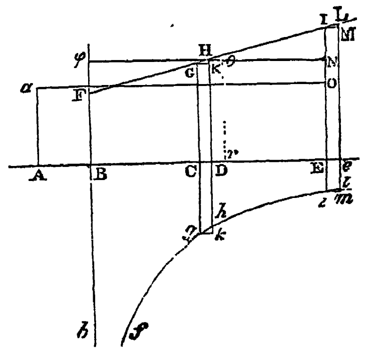
We may learn from this investigation of the value of an accelerating force, that no finite change of velocity is effected in an instant by the action of an accelerating force. When the fig. 18 is used for the scale of accelerations, and they are represented by the ordinates of the line *hko*, the increment of velocity is represented by an area, that is, by a slip of the whole area; which slip must have some altitude, or must occupy some portion of the abscissa which represents time. Some portion of time, however small it may be, must elapse before any measurable addition can be made to the velocity. The velocity must change *continually*. As no motion can be conceived as instantaneous, because this would be to conceive that in one instant the moving particle is in every point of its momentary path,—so no velocity can change, by a finite quantity, in one instant, because this would be to conceive that in that instant the particle had all the intervening velocities. The instant of change is at once the last instant of the preceding velocity, and the first of the succeeding, and therefore must belong to both. This cannot be conceived, or is absurd. As a body, in passing from one part of space to another, must pass in succession through all the intermediate places; so, in passing from one velocity to another, it must in succession have all the intermediate velocities. It must be *continually* accelerated—we must not say *gradually*—however small the steps.

But to return from this digression:

More convenient manner of considering the action of forces, and more frequently coming into view.

94. The most frequent cases which come under examination do not show us the relation between the forces and times, but the relation between the forces and spaces. Thus, when a piece of iron is in the neighbourhood of a magnet, or a planet is considered in the neighbourhood of the sun, a force is acting on it in every point of its path, and we have discovered that the intensity of this force varies in a certain proportion. Thus, a spring varies in its pressure as it unbends; gunpowder presses less violently as it expands, &c. &c.

Fig. 19.



Our knowledge is generally confined to some such effect as this. We know, that while a body is moving along a line, ADE (fig 19), it is urged forward by a force, of which the intensity varies in the proportion of the ordinates BF, CG, DH, EI, &c. of the line FGHI.

To investigate the motion or change of motion produced by the action of this force, let CD be supposed a very small portion of the space s, which we may express by s'. Draw GK perpendicular to DH. Then, if we suppose that the

[1] See Barrow's *Lect. Geometr.* passim.

Of Accelerating and Retarding Forces.

force acts with the unvaried intensity CG through the whole space CD, the rectangle CDKG will express half of the increment of the square of the velocity (No. 85). We may suppose that the force acts uniformly along the adjoining small space Dr with the intensity DH. The rectangle DHor will in like manner express another half increment of the square of the velocity. And in like manner we may obtain a succession of such increments. The aggregate or sum of them all will be half the difference between the square of the velocity at B and the square of the velocity at E.

If we employ f to express the indetermined or variable intensity of the accelerating force, and v to express the variable velocity, and v' its increment *uniformly* acquired, then the rectangle CDKG will be expressed by fs'. We have seen that this is equal to vv'. Therefore, in every case where we can tell the aggregate of all the quantities fs, it is plain that we will obtain half the difference between the squares of the velocities in B and E, on the supposition that the intensity of the force was constant along each little space, and varied by starts. Then, by increasing the number and diminishing the magnitude of those little portions of the space without end, it is evident that we terminate in the expression of the real state of the case, *i. e.* of a force varying continually; and that in this case the aggregate of these rectangles occupies the whole area AEIF, and is equivalent to the fluent of fds, or to the symbol $\int fds$, used to express this fluent, which is conceived an aggregate of small rectangles fs'. And we see that this area expresses half of the augmentation of the square of the velocity. Therefore,

Most important theorem.

95. *If the abscissa* AE (fig. 19) *of a line* FGI *is the path along which a body is urged by an accelerating force, and if the ordinates* BF, CG, DH, *&c. are proportional to the forces acting in the points* B, C, D, *&c. the intercepted areas* BCGF, BEIF, *&c. are proportional to the augmentations of the square of the velocity.*[1]

Observe that the areas BCGF and DEIH are also proportional to the augmentations made on the squares of the velocities in B and in D.

Observe also, that it is indifferent what may have been the original velocity. The action of the forces represented by the ordinates make always the same addition to its square; and this addition is half the square of the velocity which those forces would generate in the body by impelling it from rest in the point A.

96. Lastly, on this head, observe, that we can state what constant or variable force will make the same augmentation of the square of the velocity by impelling the body uniformly along the same space BE, or along what space a given force must impel the body in order to produce the same increase of the square of its velocity. In the first case, we have only to make a rectangle BENφ, equal to the area BEIF, and then Bφ is the intensity of the constant force wanted. In the second case, in which the force EO is given, we must make the rectangle AαOE equal to the area BEIF, and AE is the space required.

97. The converse of this proposition, viz. *if the areas are as the increments of the square of the velocity, the ordinates are as the forces,* is easily demonstrated in the same way; for if the elementary areas CDKG and EIMe represent increments of the squares of the velocity, the accelerating forces are in the ratio compounded of the direct ratio of these rectangles and the inverse ratio of their altitudes, because these altitudes are the increments of the space (No. 85). Now the base CG of the rectangle CDKG is to the base EI of the rectangle EIMe in the same compounded ratio; therefore the force in C is to the force in E as CG to EI.

Scales of force, velocity, acceleration, time, &c.

98. The line hko (fig. 18) was called by Dr Barrow (who first introduced this extensive employment of motion into geometry) the SCALE *of velocities;* and the line FHL (fig. 19) was named by him the *scale of accelerations.* Hermann, in his *Phoronomia,* calls it the *scale of forces.* We shall retain this name, and we may call hko of fig. 18 the *scale* of accelerations, when the areas represent the velocities. Sir Isaac Newton added another scale of very great use, viz. a scale of times. It is constructed as follows.

99. Let ABE (fig. 19) be the line along which a body is accelerated, and let FHI be the scale of forces, that is, having its ordinates FB, HD, IE, &c. proportional to the forces acting at B, D, E, F, &c.; let fhi be another line so related to ABE, that Cg is to Ei in the inverse subduplicate ratio of the area BFGC to the area BFIE; or, to express it more generally, let the squares of the ordinates to the line fgi be inversely as the areas of the line FHI intercepted between these ordinates and the first ordinate drawn through B; then the times of the bodies moving from a state of rest in B are as the intercepted areas of the curve fgi.

For let CD and Ee be two very small portions of the space described in equal times. They will be ultimately as the velocities in C and E. The area FBCG is to the area FBEI as the square of Ei to the square of Cg (by construction); but the area FBCG is to FBEI as the square of the velocity at C to the square of the velocity at E (by the proposition); therefore the square of the velocity at C is to the square of the velocity at E as the square of Ei to the square of Cg; therefore Ei is to Cg as the velocity at C to the velocity at E, that is, as CD to Ee: but since Ei : Cg = CD : Ee, we have Ei × Ee = Cg × CD, and the elementary rectangles CgkD and Eime are equal, and may represent the equal moments of time in which CD and Ee were described. Thus the areas of the line fgl will represent or express the times of describing the corresponding portions of the abscissa.

We may express the nature of this scale more briefly thus. Let BE be the space described with any varied motion, and fgl a curve, such that its ordinates are inversely as the velocities in the different points of the abscissa, then the area will be as the times of describing the corresponding portions of the abscissa.

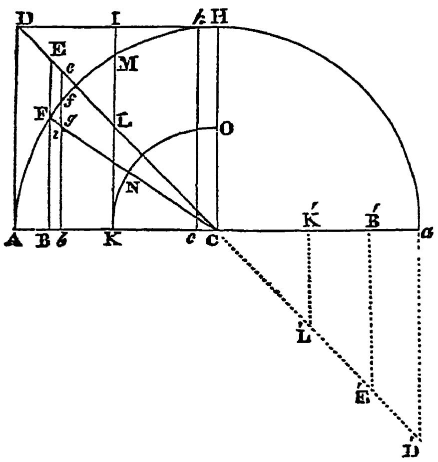
Example of the application of No 95.

100. In all the cases where our mathematical knowledge enables us to assign the values of the ordinates of the figure 19, we can obtain the law of action of the forces, or the nature of the force; and where we can assign the value of the areas from our knowledge of the proportions of the ordinates or forces, we can ascertain the velocities of the motion. We shall give an example or two, which will show the way in which we avail ourselves of the geometrical properties of figure in order to ascertain the effects of mechanical forces.

(1.) In fig. 19, let the accelerating force which impels the body along the line AB be constant, and let the body be previously at rest in B; the line which bounds the ordinates that represent the forces must be some line φHN parallel to AB. The area BDHφ is to the area BENφ as the square of the velocity at D to the square of the velocity at E. These areas, having equal bases DH and EN, are as their altitudes BD and BE; that is, the spaces described are as the squares of the acquired velocities. And we see that this characteristic mark of uniformly accelerated motion is included in this general proposition.

[1] Newton's *Principia*, i. 39.

Fig. 20.



101. (2.) Let us suppose that the body is impelled from A (fig. 20), towards the point C, by a force proportional to its distance from that point. This force may be represented by the ordinates DA, EB, *eb*, &c. to the straight line DC. We may take any magnitude of these ordinates; that is, the line DC may make any angle with AC. It will simplify the investigation if we make the first force AD = AC. About C describe the circle AH*a*, cutting the ordinate EB in F; let *eb* be another ordinate, cutting the circle in *f* very near to F; draw CH perpendicular to AC, and make the arch H*h* = *f*F, and draw *hc* parallel to HC; join FC and DH, and draw F*g* perpendicular to *fb*. Let IML be another ordinate.

The area DABE is to the area DAKL as the square of the velocity at B to the square of the velocity at K. But DABE is the excess of the triangle ADC above the triangle EBC, or it is half of the excess of the square of CA or CF above the square of CB, that is, half the square of BF. In like manner, the area DAKL is equal to half the square of KM; but halves have the same ratio as the integers; therefore the square of BF is to the square of KM as the square of the velocity at B to the square of the velocity at K; therefore the velocity at B is to the velocity at K as BF is to KM. The velocities are proportional to the sines of the arches of the quadrant AFH described on AC.

Cor. 1. The final velocity with which the body arrives at C is to the velocity in any other point B as radius to the sine of the arch AF.

Cor. 2. The final velocity is to the velocity which the body would acquire by the uniform action of the initial force at A as 1 to $\sqrt{2}$; for the rectangle DACH expresses the square of the velocity acquired by the uniform action of the force DA; and this is double of the triangle DAC; therefore the squares of these velocities are as 1 and 2, and the velocities are as $\sqrt{1}$, and $\sqrt{2}$, or as 1 to $\sqrt{2}$.

102. *Cor.* 3. The time of describing AB is to the time of describing AC as the arch AF to the quadrant AFH.

For when the arch F*f* is diminished continually, it is plain that the triangle *fi*F is ultimately similar to CFB, by reason of the equal angles C*ib* (or CFB) and *fi*F, and the right angles CBF and *f*F*i*; therefore the triangles *fg*F and CBF are also similar. Moreover, B*b* is equal to F*g*, F*f* is equal to *h*H, which is ultimately equal to *c*C; therefore, since the triangles *fg*F and CFB are similar, we have F*g* : F*f* = FB : CF = FB : HC; therefore B*b* is to *c*C as FB to HC, that is, as the velocity at B to the velocity at C; therefore B*b* and *c*C are described in equal moments when indefinitely small; therefore equal portions F*f*, *h*H, of the quadrant correspond to equal moments of the accelerated motion along the radius AC; and the arches AF, FM, MH, &c. are proportional to the times of describing AB, BK, KH, &c.

Cor. 4. The time of describing AC with the unequally accelerated motion, is to the time of describing it uniformly with the final velocity as the quadrantal arch is to the radius of a circle; for if a point move in the quadrantal arch so as to be in F, *f*, M, H, &c. when the body is in B, *b*, K, C, it will be moving uniformly, because the arches are proportional to the times of describing those portions of AC; and it will be moving with the velocity with which the body arrives at C, because the arch *h*H is ultimately = C*c*. Now if two bodies move uniformly with this velocity, one in the arch AFH, and the other in the radius AC, the times will be proportional to the spaces uniformly described; but the time of describing AFH is equal to the time of the accelerated motion along AC, therefore the proposition is manifest.

103. *Cor.* 5. If the body proceed in the line C*a*, and be retarded in the same manner that it was accelerated along AC, the time of describing AC uniformly with the velocity which it acquires in C is to the time of describing AC*a* with the varied motion, as the diameter of a circle to the circumference; for because the momentary retardations at K′, B′, &c. are equal to the accelerations at K and B, &c. the time of describing AC*a* is the same with that of describing AH*a* uniformly with the greatest velocity; that is, to the time of describing AC uniformly as AH*a* to AC, or as the circumference of a circle to the diameter; therefore, &c. N. B. In this case of retarding forces it is convenient to represent them by ordinates K′L, B′E, *a*D′, lying on the other side of the axis AC*a*; and to consider the areas bounded by these ordinates as subtractive from the others. Thus the square of the velocity at K′ is expressed by the whole area DACK′L′C, the part C′K′L′ being negative in respect of the point DAC. This observation is general.

Cor. 6. The time of moving along KC, the half of AC, by the uniform action of the force at A, is to that of describing AC*a* by the varied action of the force directed to C, and proportional to the distance from it, as the diameter of a circle to the circumference; for when the body is uniformly impelled along KC by the constant force IK, the square of the velocity acquired at C is represented by half the rectangle IKCH, and therefore it is equal to the velocity which the variable force generates by impelling it along AC (by the way, an important observation). The body will describe AC uniformly with this velocity in the same time that it is uniformly accelerated along KC. Therefore by *Cor.* 5 the proposition is manifest.

Cor. 7. If two bodies describe AC and KC by the action of forces which are everywhere proportional to the distances from C, their final velocities will be proportional to the distances run over, and the times will be equal.

For the squares of the final velocities are proportional to the triangle ADC, LKC, that is, to AC^2, KC^2, and therefore the velocities are as AC, KC. The times of describing AC and KC uniformly, with velocities proportional to AC and KC, must be equal; and these times are in the same ratio (viz. that of radius to $\frac{1}{4}$ of the circumference) to the times of describing AC and KC with the accelerated motion. Therefore, &c.

Thus, by availing ourselves of the properties of the circle, we have discovered all the properties or characters of a motion produced by a force always directed to a fixed point, and proportional to the distance from it. Some of these are remarkable, such as the last corollary; and they are all important, for there are innumerable cases where this law of action obtains in nature It is nearly the law

of action of a bowstring, and of all elastic bodies, when their change of figure during their mutual action is moderate; and it has been by the help of this proposition first demonstrated in a particular case by Lord Brouncker and Mr Huygens, that we have been able to obtain precise measures of time, and consequently of actual motions, and consequently of any of the mechanical powers of nature. It is for this reason, as well as for the easy and perspicuous employment of the mathematical method of proceeding, that we have selected it.

Instead of giving any more particular cases, we may observe in general, that if the intensity of the force be proportional to any power whose index is $n-1$ of the distance, and if a be the distance from the fixed point at which the body begins to be accelerated, and x its distance from the point in any part of the motion, the velocity will be $\doteqdot \sqrt{\overline{a^n - x^n}}$. This is very plain, because the increment CGHD of the area of fig. 19, which is also the increment of the square of the velocity, is $\doteqdot x^{n-1}dx$, and the area is $\doteqdot x^n$; and the whole area, corresponding to the distance a, is a^n. Therefore the portion of the area lying beyond the distance x is $a^n - x^n$. This is as the square of the velocity, and therefore the velocity is as the square root $\sqrt{\overline{a^n - x^n}}$ of this quantity.

This proposition, $fds \doteqdot vdv$, or $f \doteqdot \frac{vdv}{ds}$, is the 39th of the first book of Newton's *Principia*, and is perhaps the most important in the whole doctrine of dynamics, whether employed for the investigation of forces or for the explanation of motions. It furnishes the most immediate data for both purposes, but more especially for the last. By its help Sir Isaac Newton was able to point out the numerous disturbances of the planetary motions, and to separate them from each other; thus unravelling, as it were, that most intricate motion in which all are blended together. He has given a most wonderful specimen of its application in his Lunar Theory.

We now are able to explain all the puzzling facts which were adduced by Leibnitz and his partisans in support of their measure of the forces of bodies in motion. We see why four springs, equally bent, communicate but a double velocity, and nine springs but a triple velocity; why a bullet moving twice as fast will penetrate an earthen rampart to a quadruple depth, &c. &c.

Conservatio virium vivarum.

This theorem also gives a most perspicuous explanation of the famous doctrine called *conservatio virium vivarum.* When perfectly elastic bodies act on each other, it is found that the sum of the masses multiplied by the squares of the velocities is always the same. This has been substituted, with great encomiums, by the German philosophers, in place of Descartes's principle, that the quantity of motion in the universe, estimated in one direction, remains always the same. They are obliged, however, to acknowledge, that in the actions of perfectly hard bodies, there is always a loss of *vis viva,* and therefore have denied the existence of such bodies. But there is the same loss in the mutual actions of all soft or ductile, or even imperfectly elastic, bodies; and they are miserably puzzled how to explain the fact; but both the *conservatio* and the *amissio* are necessary consequences of this theorem.

In the collision of elastic bodies, the whole change of motion is produced during the short time that the bodies are compressed, and while they regain their figure. When this is completed, the bodies are at the same distance from each other as when the mutual action began. Therefore the preceding body has been accelerated, and the following body has been retarded along equal spaces; and in every point of this space the accelerating and the retarding force has been equal. Consequently the same area of fig. 20 expresses the change made on the square of the velocity of both bodies. Therefore, if V and U are the velocities before collision, and v and u the velocities after collision, of the two bodies A and B, we must have $A \times \overline{V^2 - v^2} = B \times \overline{u^2 - U^2}$, and therefore $A \times V^2 + B \times U^2 = A \times v^2 + B \times u^2$.

But in the other class of bodies, which do not completely regain their figure, but remain compressed, they are nearer to each other when their mutual action is ended than when it began. The foremost body has been accelerated along a shorter space than that along which the other has been retarded. The mutual forces have in every instant been equal and opposite. Therefore the area which expresses the diminution of the square of the velocity must exceed the area expressing the augmentation by a quantity that is always the same when the permanent compression is the same; that is, when the relative motion is the same. $A \times \overline{V^2 - v^2}$ must exceed $B \times \overline{u^2 - U^2}$, and $A \times V^2 + B \times U^2$ must exceed $A \times v^2 + B \times u^2$.

This same theorem is of the most extensive use in all practical questions in mechanic arts; and without it mechanics can go no farther than the mere statement of equilibrium.

History of No. 95 is curious.

Hermann, professor of mathematics at Pavia, one of the ornaments of the mathematical class of philosophers, has given a pretty demonstration of this valuable proposition, in the *Acta Eruditorum Lipsiæ* for 1709; and says, that having searched the writings of the mathematicians with great care, he found himself warranted to say, that Newton was the undoubted author, and boasts of his own as the first synthetical demonstration. The purpose of this assertion was not very apparent at the time; but long after, in 1746, when Hermann's papers, preserved in the town-house of Pavia, were examined, in order to determine a dispute between Maupertuis and Koenig about the claim to the discovery of *the principle of least action,* letters of Leibnitz's were found, requesting Hermann to search for any traces of this proposition in the writings of the mathematicians of Europe. Leibnitz was by this time the envious detractor from Newton's reputation, and could not but perceive that all his contorted arguments for his doctrine received a clear explanation by means of this proposition, in perfect conformity to the usual measure of moving forces. Newton had discovered this theorem long before the publication of the *Principia,* and even before the discovery of the chief proposition of that book in 1666; for in his Optical Lectures, the materials of which were in his possession in 1664, he makes frequent use of a proposition founded on this. (See No. 42.) We may here remark, that Hermann's demonstration is in every step the same with Dr Barrow's demonstration of it as a theorem merely geometrical, without speaking of moving forces (see *Lect. Geometr.* xi. p. 85, edit. 16), but giving it as an instance of the transformation of curves, which he calls *scales* of velocity, of time, of acceleration, &c. It is very true that Barrow in these mathematical lectures approached very near to both of Newton's discoveries, the fluxionary geometry, and the principles of dynamics; and the junto on the Continent, who were his continual detractors, charge him with impudent plagiarism from Dr Barrow, and even say that he has added nothing to the discoveries of his teacher. But surely Dr Barrow was the best judge of this matter; and, so far from resenting the use which Newton has made of what he had taught him, he was charmed with the genius of the *juvenis spectatissimus* his scholar, and of his own accord gave him his professorial chair, and ever after lived in the utmost harmony and friendship with him. Nay, it would even appear

from some expressions in those very lectures, that Dr Barrow owed to young Newton the first thought of making such extensive use of motion in geometry. We recommend this work of Barrow's to the serious perusal of our readers, who wish to acquire clear notions of the science of motion, and an elegant taste in their mechanical disquisitions. After all the cultivation of this science by the commentators and followers of Newton, after the *Phoronomia* of Hermann, the *Mechanica* of Euler, the *Dynamique* of D'Alembert, and the *Mechanique Analytique* of De la Grange, which are undoubtedly works of transcendent merit and utility, the *Principia* of Newton will still remain the most pleasing, perspicuous, and elegant specimen of the application of mathematics to the science of *universal mechanics*, or what we call DYNAMICS.

The two fundamental theorems $fdt = dv$, and $fds = vdv$, enable us to solve every question of motion accelerated or retarded by the action of the mechanical powers of nature. But the employment of them may be greatly expedited and simplified by noticing two or three general cases which occur very frequently.

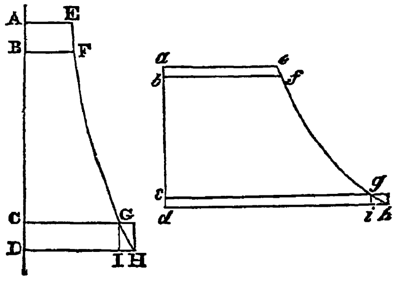
Similar instants and points, what.

104. *These may be called similar instants of time, and similar points of space which divide given portions of time, and of space in the same ratio.* Thus the middle is a similar instant of an hour or of a day, and is the similarly situated point of a foot or of a yard. The beginning of the 21st minute, and of the 9th hour, are similar instants of an hour and of a day. The beginning of the fifth inch, and of the second foot, are similar points of a foot and of a yard.

Similar actions, what.

105. *Forces may be said to act similarly when their intensities in similar instants of time, or in similar points of space, are in a constant ratio.* Thus in fig. 20, when one body is impelled towards C from A, and another from K, each with a force proportional to the distance of every point of its motion from C, these forces may be said to act similarly along the spaces AC and KC, or during the times represented by the quadrantal arches AFH, KNO. The following propositions on similar actions will be found very useful on many occasions; but we must premise a geometrical lemma.

Fig. 21.

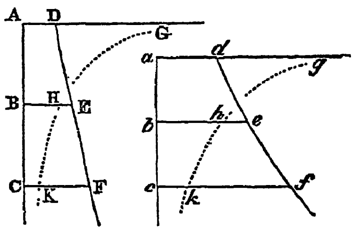


106. If there be two lines EFGH (fig. 21), *efgh*, so related to their abscisses AD, *ad*, that the ordinates BF, *bf*, drawn from similar points B and *b* of the abscisses, are in the constant ratio of AE to *ae*; then the area ADHE is to the area *adhe* as the rectangle of AD × AE to the rectangle *ad* × *ae*.

For, let each abscissa be divided into the same number of equal and very small parts, of which let CD and *cd* be one in each. Inscribe the rectangles CGID, *cgid*. Then because the number of parts in each axis is the same, the lengths of the portions CD and *cd* will be proportional to the whole abscisses AD and *ad*. And because C and *c* are similar points, CG is to *cg* as AE is to *ae*. Therefore CD × CG : *cd* × *cg* = AD × AE : *ad* × *ae*. This is true of each pair of corresponding rectangles, and therefore it is true of their sums. But when the number of these rectangles is increased, and their breadth diminished without end, it is evident that the ultimate ratio of the sum of all the rectangles, such as CDHG, to the sum of all the rectangles *cdhg*, is the same with that of the area ADHE to the area *adhe*, and the proposition is manifest.

107. *If two particles of matter are similarly impelled during given times, the changes of velocity are as the times and as the forces jointly.*

Fig. 22.



Let the times be represented by the straight lines ABC (fig. 22), and *abc*, and the forces by the ordinates AD, BE, CF, and *ad*, *be*, *cf*. Then if B and *b* are similar instants (suppose the middles) of the whole times, we have BE : *be* = AD : *ad*. Therefore, by the lemma, the area ACFD is to *acfd* as AC × AD to *ac* × *ad*. But these areas are proportional to the velocities (No. 72), and the proposition is demonstrated. For the same reason, the change of velocity during the time AB is to the change during *ab* as AB × AD to *ab* × *ad*.

Cor. 1. If the times and forces are reciprocally proportional, the changes of velocity are equal; and if the forces are inversely as the times, the changes of velocity are equal.

108. *If two particles be similarly urged along given spaces, the changes made on the squares of the velocities are as the forces and spaces jointly.*

For if AC (fig. 22) and *ac* are the spaces along which the particles are impelled, and the forces are as the ordinates AD and *ad*, the areas ACFD and *acfd* are as the changes on the squares of the velocities. But these areas are as AC × AD, and *ac* × *ad*. Therefore, &c.

Cor. 2. If the spaces are inversely as the forces, the changes of the squares of the velocities are equal; and if these are equal, the spaces are inversely as the forces.

Cor. 3. If the spaces along which the particles have been impelled from a previous state of rest, are directly as the forces, the velocities are also as the forces. For, because the changes of the squares of the velocities are as the spaces and forces jointly, they are in this case as the squares of the forces or of the spaces; but the changes of the squares of the velocities are in this case the whole squares of the velocities; therefore the squares of the velocities are as the squares of the forces, and the velocities are as the forces. N. B. This includes the motions represented in fig. 20.

109. *If two particles be similarly impelled along given spaces, from a state of rest, the squares of the times are proportional to the spaces directly, and to the forces inversely.*

Let ABC (fig. 22), *abc*, be the spaces described, and AD, *ad*, the accelerating forces at A and *a*. Let V, B express the velocity at B, and *v*, *b* the velocity at *b*.

Let GHK and *ghk* be curves whose ordinates are inversely as the velocities at the corresponding points of the abscissa. These curves are therefore exponents of the times (No. 99). Then, because the forces act similarly, we have, by the last theorem, $AC \times AD : ac \times ad = V^2, B : v^2, b, = hb^2 : HB^2$. Therefore $HB : hb = \sqrt{ac \times ad} : \sqrt{AC \times AD}$, and therefore in a con-

Of Accelerating and Retarding Forces.

stant ratio. Call this the ratio of m to n. But since the ordinates of the lines GHK, ghk, are inversely as the velocities, the areas are as the times (No. 99); and since these ordinates are in the constant ratio of m to n, the areas are in the ratio of AC $\times$ m to $ac \times n$. Therefore (calling the times of the motions T and t), we have

$\mathrm{T} : t = m \times \mathrm{AC} : n \times ac$; and therefore
$\mathrm{T}^2 : t^2 = m^2 \times \mathrm{AC}^2 : n^2 \times ac^2$. But
$m^2 : n^2 = ac \times ad : \mathrm{AC} \times \mathrm{AD}$. Therefore
$\mathrm{T}^2 : t^2 = ac \times ad \times \mathrm{AC}^2 : \mathrm{AC} \times \mathrm{AD} \times ac^2$,
or $\mathrm{T}^2 : t^2 = ad \times \mathrm{AC} : \mathrm{AD} \times ac$.

$$\text{Or } \mathrm{T}^2 : t^2 = \frac{\mathrm{AC}}{\mathrm{AD}} : \frac{ac}{ad}.$$

The attentive reader will observe that these three propositions give a great extension to the theorems which were formerly deduced from the nature of uniformly accelerated motion, or of uniform action of the forces, and were afterwards demonstrated to obtain in the momentary action of forces any how variable.

The first of the three propositions, $\mathrm{V} : v = \mathrm{F} \times \mathrm{T} : f \times t$, is the extension of the theorem $fdt = dv$. The second, $\mathrm{V}^2 : v^2 = \mathrm{F} \times \mathrm{S} : f \times s$, is the extension of the theorem $fds = vdv$. And the third, $\mathrm{T}^2 : t^2 = \frac{\mathrm{S}}{\mathrm{F}} : \frac{s}{f}$, is the extension of $f = \frac{ds}{d(t^2)}$, or of $fd\ (t^2) = ds$. These theorems hold true of all *similar* actions; and, only for this reason, are true of uniformly accelerated motions, or uniform actions.

Aggregate of many equal accelerating forces.

There remains one thing more to be said concerning the action of accelerating forces. Their magnitude is ascertained by their effect. Therefore that is to be considered as a double force which produces a double quantity of motion. Therefore when a body A contains twice the number of equal atoms of matter, and acquires the same velocity from the action of the force F, that another body a, containing half the number of atoms, acquires from the action of a force f, we conceive F to be double of f. That this is a legitimate inference appears clearly from this, that we conceive the sensible weight of a body, or that pressure which it exerts on its supports, as the aggregate of the equal pressure of every atom accumulated perhaps on one point; as when the body hangs by a thread, and, by its intervention, pulls at some machine. Without inquiring in what manner or by what intervention this accumulation of pressure is brought about, we see clearly that it results from the equal accelerating force of gravity acting immediately on each atom. When this weight is thus employed to move another body by the intervention of the thread, which is attached to one point perhaps of that body, it puts the whole into motion, generating a certain velocity v in every atom, by acting uniformly during the time t. We conceive each atom to have sustained the action of an equal accelerating force whose measure is $\frac{v}{t}$. Without considering how this force is exerted on each atom, or by what it is immediately exerted, or how it is diffused through the body from the point to which the weight of the other body is applied by means of the thread; we still consider it as the aggregate of the action of gravity on each atom of that other body. Moreover, attending only to the motion produced by it, and perhaps not knowing the weight of the impelling body, we measure it, as a moving force, by considering it as the aggregate of the forces propagated to each atom of he impelled body, and measured by $\frac{v}{t}$. If we know that the impelled body contains the number m of atoms, the aggregate of forces is $m\frac{v}{t}$, or $\frac{mv}{t}$.

Of Deflecting Forces.

But since we measure forces by the quantity of motion which they produce, we must conceive, that when the same force is applied to a body which consists of n particles, and produces the velocity u, by acting uniformly during the same time t, the force $n\frac{u}{t}$ is equal to the force $m\frac{v}{t}$.

Moving force, motive force, vis motrix, as distinguished from accelerating force.

110. Sir Isaac Newton found it absolutely necessary, in the disquisitions of natural philosophy, to keep this circumstance of acceleration clear of all notions of quantity of matter, or other considerations, and to contemplate the affections of motion only. He therefore considered $\frac{v}{t}$ as the true original measure of accelerating force, and $m\frac{v}{t}$ as an aggregate. He therefore calls the aggregate a *vis motrix*, a *moving force*, measured by the *quantity of motion* that it generates. And he confines the term *accelerating force* to the quantity $\frac{v}{t}$ measured by the *acceleration* or *velocity* only. It would be convenient, therefore, also to confine the symbol f to $m\frac{v}{t}$, and to retain the symbol a for expressing the accelerating force $\frac{v}{t}$.

This appellation of *motive force* is perfectly just and simple; for we may conceive it as the same with the accelerating force which produces the velocity m times v in one particle, by acting on it uniformly during the time t. This motion of one particle having the velocity mv, is the same with that of m particles having each the velocity v.

If therefore a motive force f act on a body consisting of m particles, the accelerating force a is $= \frac{f}{m}\frac{v}{t}$.

Therefore the three last propositions concerning the similar, the uniform, or the momentary actions of *moving* forces, when expressed in the most general terms, are,

$$v' \doteq \frac{f}{mt'},$$
$$v^{2\prime} \doteq \frac{fs'}{m}, \text{ or } vdv = \frac{fds}{m},$$
$$t^2 \doteq \frac{ms'}{f}.$$

OF DEFLECTING FORCES.

Deflecting forces.

111. When we observe the direction of a body to change, we unavoidably infer the agency of a force which acts in a direction that does not coincide with that of the body's motion; and we may distinguish this circumstance by calling it a *deflecting force*. We have already shown how to estimate and measure this deflecting force, by considering it as competent to the production of that motion which, when compounded with the former motion, will produce the new motion (No. 44). Now, as all changes of motion are really compositions of motions or forces, it

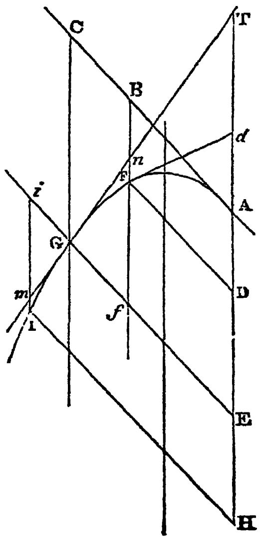
Of Deflecting Forces.

is evident that we shall explain the action of deflecting forces when we show this composition.

Alteration of deflections are continual, and produce curvilineal motions.

We may almost venture to say *a priori*, that all deflections must be continual, or exhibit curvilineal motions: for as no finite velocity, or change of velocity, can be produced in an instant by the action of an accelerating force, no polygonal or angular deflection can be produced; because this is the composition of a finite velocity produced in an instant. Deflective motions are all produced by the composition of the former motion, having a finite velocity, with a transverse motion continually accelerated from a state of rest. Of this we can form a very distinct notion, by taking the simplest case of such accelerated motion, namely, a uniformly accelerated motion.

Fig. 23.



Example. Determination of the path,

112. Let a body be moving in the direction AC (fig. 23) with any constant velocity, and when it comes to A, let it be exposed to the action of an accelerating force, acting uniformly in any other direction AE. This alone would cause the body to describe AE with a uniformly accelerated motion, so that the spaces AD, AE, would be as the squares of the times in which they are described. Therefore, if AB be the space which it would have described uniformly in the time that it describes AD by the action of the accelerating force, and AC the space which it would have described uniformly while it describes AE by the action of the accelerating force, nothing more is wanted for ascertaining the real motion of the body but to compound the uniform motion in the direction AC with the uniformly accelerated motion in the direction AE. AD is to AE as the square of the time of describing AD to the square of the time of describing AE; that is, as the square of the time of describing AB to the square of the time of describing AC; that is, as AB^2 to AC^2 (by reason of the uniform motion in AC). This composition is performed by taking the simultaneous points B, D, and the simultaneous points C, E, and completing the parallelograms ABFD, ACGE. The body will be found in the points F and G in the instants in which it would have been found at B and C by the uniform motion, or in D and E by the accelerated motion. In the same manner may be found as many points of the real path as we please. It is plain that these points will be in a line AFG, so related to AE that $AD : AE = DF^2 : EG^2$; or so related to the original motion AC, that $AB^2 : AC^2 = BF : CG$, &c. This line is therefore a parabola, of which AE is a diameter, DF and EG are ordinates, and which touches AC in A.

and of the motion in this path.

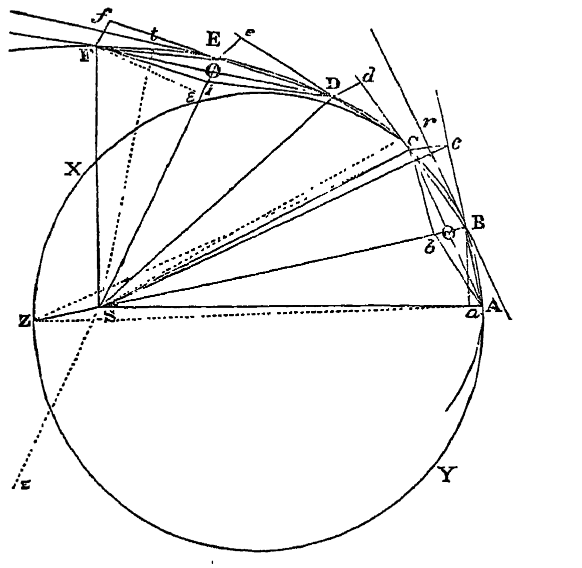
Having thus ascertained the path of the body, we can also ascertain the motion in that path; that is, the velocity in any point of it. We know that the velocity in the point G is to the velocity of the uniform motion in the direction AC as the tangent TG is to the ordinate EG; because this is the ultimate ratio of the momentary increment of the arch AFG to the momentary increment of the ordinate EG. Thus is the velocity in every point of the curve determined. We have taken it for granted that the line of projection touches the path, and that the direction in every point is that of the tangent. To suppose that the curve, in any portion of it, coincides with the tangent, is to suppose that the body is not deflected, that is, is not acted on by a transverse accelerating force; and to suppose that the tangent makes a finite angle with any part of the path, is to suppose that the deflection is not continual, but by starts, both of which are contrary to the conditions of the case. No straight line can be drawn between the direction of the body and the succeeding portion of the path, otherwise we must again suppose that the deflection is subsultory, and the motion angular.

113. But while the investigation is so easy when the direction and intensity of the deflecting force in every point of the curve are known, the investigation of the deflecting force from the observed motion is by no means easy. The observed curvilineal motion always arises from a composition of a uniform motion in the tangent with some transverse motion; but the same curvilineal motion may be produced by compounding the uniform motion in the tangent with an infinity of transverse motions, and the law of action will be different in these transverse motions according as their directions differ. We must learn not only the intensity of the deflecting force, and the law of its variation, but also its direction in every point of the curve. It is not easy to find general rules for discovering the direction of the transverse force; most commonly this is indicated by extrinsic circumstances. The deflecting force is frequently observed to reside in or to accompany some other body. It may be presumed, therefore, that it acts in the direction of the line drawn to or from that body; yet even this is uncertain. The most general rule for this investigation is to observe the place of the body at several intervals of time before and after its passing through the point of the curve, where we are interested to find its precise direction. We then draw lines joining those places of the tangent where the body would have been by the uniform motion only. We shall perhaps observe these lines of junction keep in parallel positions: we may be assured that the direction of the transverse force is the same with that of any of these lines. This is the case in the example just now given of a parabolic motion; but when these lines change position they will change it gradually, and their position in the point of contact is that to which their positions on both sides of it gradually approximate.

But all this is destitute of the precision requisite in philosophical discussion. We are indebted to Sir Isaac Newton for a theorem which ascertains the direction of the transverse force with all exactness, in the cases in which we most of all wish to attain mathematical accuracy, and which not only opened the access to those discoveries which have immortalized his name, but also pointed out to him the path he was to follow, and even marked his first steps. It therefore merits a very particular treatment.

Of Deflecting Forces.

Fig. 24.



Newton's fundamental theorem for the direction of a deflecting force.

114. If a body describes a curve line ABCDEF (fig. 24) lying in one plane, and if there be a point S so situated in this plane that the line joining it with the body describes areas ASB, ASC, ASD, &c. proportional to the times in which the body describes the arches AB, AC, AD, &c. the force which deflects the body from rectilineal motion is continually directed to the fixed point S.

Let us first suppose that the body describes the polygon ABCDEF, &c. formed of the chords AB, BC, CD, DE, EF, &c. of this curve, and, for greater simplicity of argument, let us consider areas described in equal successive times; that is, let us suppose that the triangles ASB, BSC, CSD, &c. are equal, and described in equal times. Make $Bc = AB$, and draw cS.

Areas = to the times indicate central forces.

Had the motion AB suffered no change in the point B, the body would have described Bc in the equal moment succeeding the first; but it describes BC. The body has therefore been deflected by an external force, and BC is the diagonal of a parallelogram (No. 45, 46), of which Bc is one side, and cC is another. The deflecting force will be discovered, both in respect of direction and intensity, by completing the parallelogram BcCb. Bb is the space which the deflecting force would have caused the body to describe in the time that it describes Bc or BC. Because Bc is equal to BA, the triangles BSc, BSA are equal. But, by the nature of the motion, BSA is equal to BSC; therefore the triangles BSC and BSc are equal. They are also on the same base BS; therefore they lie between the same parallels, and Cc is parallel to SB. But cC is parallel to Bb; therefore Bb coincides with BS, and the deflecting force at B is directed toward S. By the same argument, the deflecting force at the angles D, E, F, &c. is directed to S.

Now, let the sides of the polygon be diminished, and their number increased without end. The demonstration remains the same, and continues, when the polygon finally coalesces with the curve, and the deflection is continual.

When areas are described proportional to the times, equal areas are described in equal times; and therefore the deflection is always directed to S. Q. E. D.

Centre of deflection. Centre of forces. Central forces.

The point S may, with equal propriety of language, be called the *centre of deflection*, or *the centre of forces;* and forces which are thus continually directed to one fixed point may be distinguished from other deflecting forces by the name *central forces*.

Radius vector.

The line joining the centre of forces with the body, and which may be conceived as a stiff line carrying the body round, is usually named the *radius vector*.

Central forces produce areas proportional to the times.

115. The converse of this proposition, viz. that if the deflecting forces be always directed to S, the motion is performed in one plane, in which S is situated, and areas are described proportional to the times, is easily demonstrated by reversing the steps of this demonstration. The motion will be in the plane of the lines SB and Bc, because the diagonal BC of the parallelogram of forces is in the plane of the sides. Areas are described proportional to the times; for Cc being parallel to SB, the triangles SCB and ScB are equal; and therefore SCB and SAB are equal, &c. &c.

Velocity is inversely as the perpendicular from the centre.

116. *Cor.* 1. When a body describes areas round S proportional to the times, or when it is continually deflected toward S, or acted on by a transverse force directed to S, the velocities in the different points A and E of the curve are inversely proportional to the perpendiculars Sr and St, drawn from the centre of forces to the tangents in those points; that is, to the perpendiculars from the centre on the momentary directions of the motion: for since the triangles ASB, ESF are equal, their bases AB, EF are inversely as their altitudes Sr, St; but these bases being described in equal times, are as the velocities, and they ultimately coincide with the tangents at A and E.

117. *Cor.* 2. If $B\alpha$ and $F\varepsilon$ be drawn perpendicular to SA and SE, we have $SA \times B\alpha = SE \times F\varepsilon$, and $SA : SE = F\varepsilon : B\alpha$. For $SA \times B\alpha$ is double of the triangle BSA, and $SE \times F\varepsilon$ is double of the equal triangle SFE.

Angular velocity is inversely as the square of the distance from the centre of forces.

118. *Cor.* 3. The angular velocity round S, that is, the magnitude of the angle described in equal times by the radius vector, is inversely proportional to the square of the distance from S. For when the arches AB, EF are diminished continually, the perpendiculars $B\alpha$ and $F\varepsilon$ will ultimately coincide with arches described round S with the radii SB and SF. Now the magnitude of an angle is proportional to the length of the arch which measures it directly, and to the radius of the arch inversely. In any circle, an arch of two inches long measures twice as many degrees as an arch one inch long; and an arch one inch long contains twice as many degrees of a circle whose radius is twice as short. Therefore, ultimately, the angle ASB is to the angle ESF as $B\alpha$ to $F\varepsilon$, and as SF to SB jointly; that is, as $B\alpha \times SF$ to $F\varepsilon \times SB$. But $B\alpha : F\varepsilon = SE : SA$ (Cor. 2); therefore $ASB : ESF = SE \times SF : SB \times SA$, $=$ ultimately $SE^2 : SB^2$.

This corollary gives us an ostensible mark, in many very important cases, of the action of a deflecting force being always directed to a fixed point. We are often able to measure the angular motion when we cannot measure the real velocities.

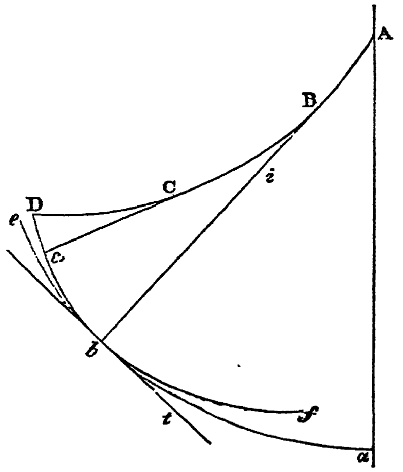
Intimate connection of dynamics and the higher geometry.

Having thus discovered the chief circumstances which enable us to ascertain the direction of the deflecting force, we proceed to investigate the quantity of this deflective determination in the different points of a curvilineal motion. This is a more difficult task. The momentary effect of the deflecting force is a small deviation from the tangent; and this deviation is made with an accelerated motion. The law of this acceleration regulates the curvature of the path, and is to be determined by it. We may be allowed to observe by the way, that it appears clearly, from the form in which Newton has presented all his dynamical theorems, that we are indebted to these problems for the immense improvement which he has made in geometry by his invention of fluxions. The purposes he had in view suggested to his penetrating mind the means for attaining them; and the connection between dynamics and geometry is so intimate, that the same theorems are in a manner common to both. This is

particularly the case in all that relates to curvature. Or shall we say that the geometry of Dr Barrow suggested the dynamical theorems to Newton? We have seen how the curvature of a parabola is produced by a force acting uniformly. The *momentary* action of all finite forces may be considered as uniform, and therefore the curvature will be that of some portion of some parabola; but it will be difficult to determine the precise degree without some farther help. We are best acquainted with the properties of the circle, and will have the clearest notions of the curvature of other curves by comparing them with circles.

Measure of curvature. The curvature of a circular arch of given length is so much greater as its radius is shorter, for it will contain so many more degrees in the same length; and therefore the change of direction of its extremities is so much greater. Curvatures may always be measured by the length of the arch directly, and the radius inversely.

Fig. 25.



Evolution and involution of curves. 119. Suppose a thread made fast at one end of a material curve ABCD (fig. 25), and applied to it in its whole length. Taking hold of its extremity D, unfold it gradually from the curve DCBA; the extremity D will describe another curved D*cba*. This geometrical operation is called the *evolution* of curves, and D*cba* is called the *evolute* of DCBA, which is called the *involute* of D*cba*. Perhaps this denomination has been given from the genesis of the area or surface contained by the two lines, which is folded up and unfolded somewhat like a fan. When the describing point is in *b*, the thread *b*B is undoubtedly the momentary radius of a circle *ebf*, whose centre is B, the point of the involute which it is just going to quit. The momentary motion of *b* is the same, whether it is describing an arch of the evolute passing through *b*, or an arch of a circle round the centre B. The same line *bt*, perpendicular to the thread *b*B, touches the circle *ebf* and the curve D*ba* in the point *b*. This circle *ebf* must lie within the curve D*ba* on the side of *b*B toward *a*, because on this side the momentary radius is continually increasing. For similar reasons, the circle *ebf* lies without the curve on the other side of *b*B. Therefore the circle *ebf* both touches and cuts the curve D*ba* in the point *b*. Moreover, because every portion of the curve between *b* and D is described with radii that are shorter than *b*B, it must be more incurvated than any portion of the circle *ebf*. For similar reasons, every portion of the curve between *b* and *a* must be less incurvated than this circle; therefore the circle has that precise degree of curvature that belongs to the curve in the point *b*; it is therefore called the *equicurve circle*, or the *circle of curvature*, and B is called the centre, and B*b* the *radius of curvature*. It is easy to perceive that no circle can be described which shall touch the curve in *b*, and come between it and the circle *ebf*; for its centre must be in some point *i* of the radius *b*B. If *ib* be less than B*b*, it must fall within the curve on both sides of *b*, and if *ib* is greater than B*b*, the circle must fall without the curve on both sides of B*b*. The circle *ebf* lies closer to the curve, has closer contact with it than any other, and has therefore got the whimsical name of *osculating circle;* and this sort of contact was called *osculation*.

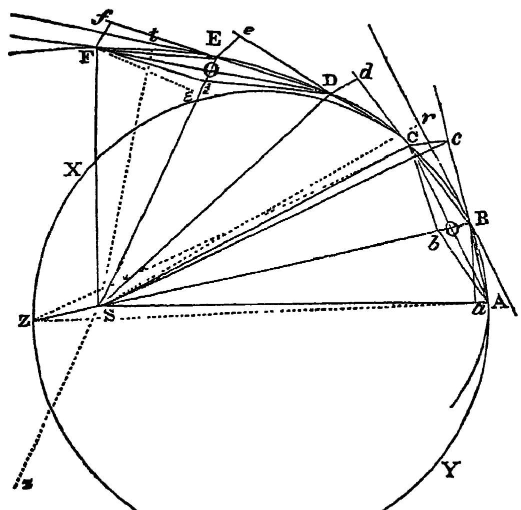
Circle of curvature. Equicurve circle.

This view of the genesis of curve lines is of particular use in dynamical discussions. It exhibits to the eye the perfect sameness of the momentary motion, and therefore of the momentary deflection, in the curve and in the equicurve circle, and leaves the mind without a doubt but that the forces which produce the one will produce the other. A great variety of curves may be described in this way. If perpendiculars be drawn to the curve D*ba* in every point, they will intersect each other, each its immediate neighbour, in the circumference of the curve DBA; and geometry teaches us how to find the curve DBA which shall produce the curve D*ba* by evolution. (See Fluxions.)

It is a matter worthy of remark, that the path of a body that is deflected from rectilineal motion by a *finite* force, varying according to any law whatever, may always be described by evolution. This includes almost every case of the action of deflecting forces; none being excepted but when, by the opposite action of different forces, the body is in equilibrio in one single point of its path.

Our task is now brought within a very narrow compass, namely, to measure the deflection in the arch of a circle.

Fig. 26.



Had the motion represented in fig. 26 been polygonal, it is plain that the deflecting force in the point B is to that in the point E as the diagonal B*b* of the parallelogram ABC*b* to the diagonal E*i* of the parallelogram DEF*i;* therefore let ABCZY be a circle passing through the points A, B, and C, and let the radius vector BS cut the circumference in Z; draw AZ, CZ, and the diagonal AC, which necessarily bisects and is bisected by the diagonal B*b*. The triangles *b*BC and CBZ are similar; for the angle C*b*B is equal to the alternate angle AB*b* or ABZ, which is equal to the angle ACZ, standing on the same chord AZ. And the angle CB*b*, or CBZ, is equal to CAZ, standing on the same chord CZ; therefore the remaining angle *b*CB is equal to the remaining angle

AZC; therefore ZA is to AC as BC to B*b*, and B*b* $= \frac{AC \times BC}{AZ}$. In like manner E*i* $= \frac{DF \times EF}{Dz}$.

Measure of deflecting forces. Now let the points A and C continually approach, and ultimately coalesce with B; it is evident that the circle ABCZY is ultimately the equicurve or coinciding circle at the point B, and that AS ultimately coalesces with and is equal to BS, and that AC×BC is ultimately $2BC^2$; therefore ultimately $Bb : Ei = \frac{2BC^2}{BZ} : \frac{2EF^2}{Ez}$, or $= \frac{BC^2}{\frac{1}{2}BZ} : \frac{EF^2}{\frac{1}{2}Ez}$.

Now BC and EF being described in equal times, are as the velocities: B*b* and E*i* are the measures of the velocities which the deflective forces at B and E would generate in the time that the body describes BC or EF, and are therefore the measures of those forces. *They are as the squares of the velocities directly, and inversely as those chords of the equicurve circles which have the directions of the deflection.*

Observe that B*b* or E*i* is the third proportional to half of the chord and the arch described; for $Bb : BC = BC : \frac{BZ}{2}$.

It is evident, that as the arches AB, BC, continually diminish, AC is ultimately parallel to the tangent B*r*, and BO is equal to the actual deflection from the tangent. The triangles BOC and AOZ are similar, and $BO = \frac{OC^2}{OZ}$, or ultimately $= \frac{BC^2}{BZ}$. We may measure the forces by the actual deflections, because they are the halves of the measures of the generated velocities; and we may say that

Measure of deflection. 120. *The actual momentary deflection from the tangent is a third proportional to the deflective chord of the equicurve circle and the arch described during the moment.*

Caution. Either of these measures may be taken, but we must take care not to confound them. The first is the most proper, because the change produced on the body (which is the *immediate* effect and measure of the force) is the determination left inherent in it to move with a certain velocity. This is the measure also which we obtain by means of the differential or fluxionary calculus; but the other measure must be obtained when our immediate object is to mark the actual path of the body. The steps of this demonstration, which is Newton's, naturally terminate in the equicurve circle, and give at once the immediate measure of the deflecting force. At the same time the reader must perceive that this measure does not depend on the force being always directed to one centre; it is enough that the two sides of the polygon, in immediate succession, are described in equal times. This is necessary in order that ABC*b* may be a parallelogram, and that the diagonals AC and B*b* may mutually bisect each other.

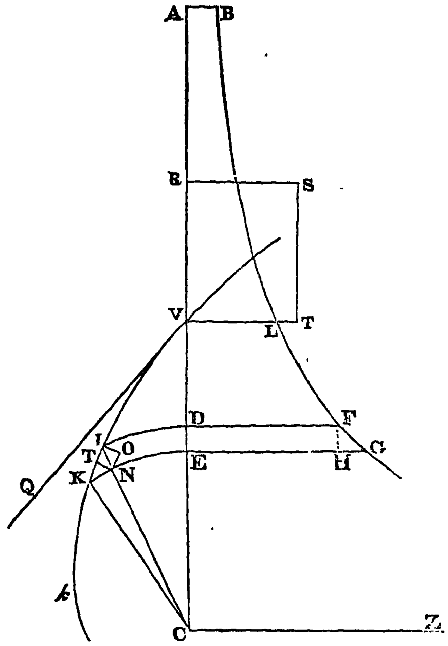
Thus have we obtained a measure of deflecting force, and, in the most important cases, a method of discovering its direction. It only remains to point out the relation between the intensity of the force, the curvature of the path, and the velocity of the motion. These three circumstances have a necessary connection; for we see that the intensity is expressed by certain values of the other two in the formula $f \doteqdot \frac{\text{Arch}^2}{\frac{1}{2}\text{Chord}}$, or $f = \frac{2\,BC^2}{BZ}$. The deflective velocity B*b* is acquired in the time that the body describes BC; therefore the deflective velocity is to the velocity in the curve as B*b* to BC. The velocity B*b* is acquired by an accelerated motion along BO; for while, by progressive motion, the body describes BC, it deflects from the tangent through a space equal to the half of B*b*, because the momentary action of the deflecting force may be considered as uniform. The progressive velocity BC may be generated by the same force uniformly acting through a space greater than BC; call this space *x*. The spaces along which a body must be uniformly impelled in order to acquire different velocities are as the squares of those velocities; therefore $Bb^2 : BC^2 = Bo : x$; but $Bb : BC = BC : \frac{1}{2}BZ$; therefore $Bb^2 : BC^2 = Bb : \frac{1}{2}BZ$, and $Bb : \frac{1}{2}BZ = Bo : x$, and $Bb : Bo = \frac{1}{2}BZ : x$; but B*o* is $\frac{1}{2}$ of B*b*, therefore *x* is $\frac{1}{4}$ of BZ; that is,

121. *The velocity in any point of a curvilineal path is that which the deflecting forces in that point would generate in the body by impelling it uniformly along one fourth part of the deflective chord of the equicurve circle.* If the velocity increase, the chord of the equicurve circle must increase; that is, the path becomes less incurvated. If the force be increased, the curvature will also increase, for the chord of curvature will be less.

There is another general observation to be made on the velocity of a curvilineal motion, which greatly assists us in our investigation.

122. *If a body describes a curve by the action of a force always directed to a fixed point, and varying according to any proportion whatever of the distances from that point, and if another body, acted on by the same centripetal force, move toward the centre in a straight line, and if in any one case of equal distances from the centre of force the two bodies have equal velocities, they will have equal velocities in every other case of equal distances from the centre.* **Comparison of orbital motion with direct approach to the centre.**

Fig. 27.



Let one body be impelled from A (fig. 27) toward C along the straight line AVDEC, and let another be deflected along the curve line VIK*k*. About the centre C describe concentric arches ID, KE, very near to each other, and cutting the curve in I and K, and the line AC in D and E; draw IC, cutting KE in N, and draw NT perpendicular to the arch IK of the curve, and complete the parallelogram ITNO. Let the bodies be supposed to have equal velocities at I and at D.

Then, because the centripetal forces are supposed to be the same for both bodies when they are at equal distances, the accelerating forces at D and I may be represent-

Of Deflecting Forces.

ed by the equal lines DE and IN; but the force IN is not wholly employed in accelerating the body along the arch IK, but, acting transversely, it is partly employed in incurvating the path. It is equivalent to the two forces IO and IT, of which only IT accelerates the body. Now IKN is a right-angled triangle, as is also the triangle INT; and they are similar; therefore IN : IT = IK : IN, or DE : IT = IK : DE; that is, the force which accelerates the body along DE is to the force which accelerates the body along IK as the space IK is to the space DE; therefore (No. 86) the increment of the square of the velocity acquired along DE is equal to the increment of the square of the velocity acquired along IK. But the velocities at D and I were equal, and consequently their squares were equal; and these having received equal increments, therefore the squares of the velocities at E and K are equal, and the velocities themselves are equal. And since this is the case in all the corresponding points of the line AC and the curve VIK, the velocities at all equal distances from C will be equal.

It is evident that the conclusion will be the same, if the bodies, instead of being accelerated by approaching the centre in the straight line AC, and in the curve VIK, are moving in the opposite directions from E to A, or from I to V, and are therefore retarded by the centripetal force.

Retarded curvilineal motion always accompanied by recess from the centre.

123. *Cor.* Hence it follows, that if a body be projected from any point, such as V, of the curve, in a line tending straight from the centre, with the velocity which it had in that point of the curve, it would go to a distance VA, such, that if it were impelled along AV by the centripetal force, it would acquire its former velocity in the point V; also in any point between V and A it will have the same velocity in its recess from the centre that it has there in its approach to the centre.

The line BLFG, whose ordinates are as the intensities of the centripetal force in A, V, D, E, or in A, V, I, K, may be called the *scale* or *exponent* of force; the areas bounded by the ordinates AB, VL, DF, EG, &c. drawn from any two points of the axis, are as the squares of the velocity acquired by acceleration along the intercepted part of the axis, or in any curvilineal path, while the body approaches the centre, or which are lost while the body retires from it. When we can compute these areas we obtain the velocities (see No. 102).

We are now in a condition to solve the chief problem in the science of dynamics, to which the whole of it is in a great measure subservient. The problem is this:

Inverse problem of centripetal forces.

124. Let a body be projected with a known velocity from a given point and in a given direction, and let it be under the influence of a mechanical force, whose direction, intensity, and variation, are all known; it is required to determine its path, and its motion in this path, for any given time.

This problem is susceptible of three distinct classes of conditions, which require different investigation.

1. The force may act in one constant direction; that is, in parallel lines.
2. The force may be always directed to a fixed point.
3. It may be directed to a point which is continually changing its place.

1. When the force acts in parallel lines, the problem is solved by compounding the rectilineal accelerated motion which the force would produce in its own direction with the uniform motion which the projection alone would have produced. The motion must be curvilineal when the accelerating force is transverse, in any degree whatever, to the projectile motion; and the curvilineal path must be concave on that side to which the deflecting force tends, for the force is supposed to act incessantly. The place of the body will be had for any time, by finding where the body would have been at the end of that time by each force acting alone, and by completing the parallelogram. Thus, suppose a body projected along AB (fig. 23), while it is continually acted on by a force whose direction is AD. Let D and B be the places where the body would be at the end of a given time. Then the body will, at the end of that time, be in F, the opposite angle of the parallelogram ABFD. But it has not described the diagonal AF, because its motion has been curvilineal, as we shall find by determining its place at other instants of this time.

The velocity in any point F is found by first determining the velocity at D, and making D*d* to DF as the velocity at D to the velocity at B (that is, the velocity of projection, because the motion along AB is uniform). Then draw *d*F. Then AB is to *d*F as the constant velocity of projection to the velocity at F. We have seen already (No. 112–119) that *d*F is a tangent to the curve in F. Hence we may determine the velocity at F in another way. Having determined the form of the path in the way already described, by finding its different points, draw the tangent F*d*, cutting the line DA in *d*. Then the velocity at A is to that at F as AB to *d*F. Hence also we see that the velocities in every point of the curve are proportional to the portion of the tangents at those points which are intercepted between *any* two lines parallel to AD.

Either of these methods for ascertaining the velocity, in this case of parallel deflections, will in general be easier than the general method in No. 121, by the equicurve circle.

It was thus that Galileo discovered the parabolic motion of heavy bodies.

Inverse problem of centripetal forces.

2. We must consider the motions of bodies affected by centripetal or centrifugal forces, always tending to one fixed point. This is the celebrated *inverse problem of centripetal forces*, and is the forty-second proposition of the first book of Newton's *Principia*. We shall give the solution after the manner of its illustrious author, because it is elementary in the purest sense of the word, keeping in view the two leading circumstances, and these only, namely, the motion of approach and recess from the centre, and the motion of revolution. By this judicious process, it becomes a pattern by which more refined, and, in some respects, better solutions should be modelled. At the same time we shall supply some steps of the investigation which his elegant conciseness has made him omit.

125. Let a body which tends to C (fig. 28) with a force proportional to the ordinates of the exponent BLFG, having the axis CA, be projected from V in the direction VQ, with the velocity which the centripetal force would generate in it by accelerating it along AV. It is required to determine the path or orbit VIKI of the body, and its place I in this orbit, at the end of the assigned time T.

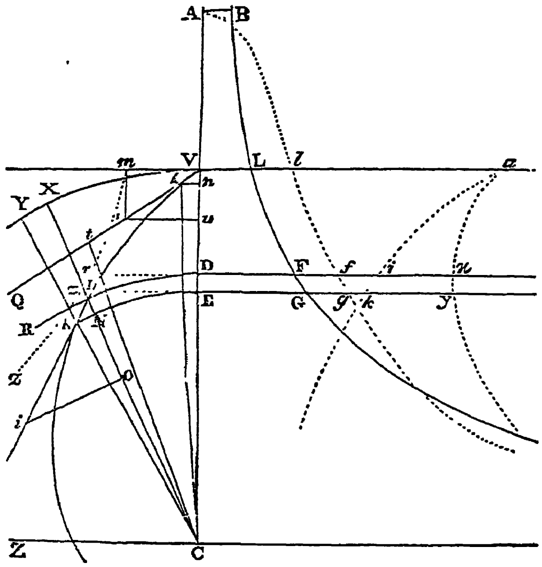
Suppose the thing done, and that I is the place of the body. About the centre C, with the distances CV and CI, describe the circles YV and ID. Draw CIX to the circumference, and draw the ordinate DF of the exponent of forces, producing it toward *x*, and produce the ordinate VL toward *a*. Let V*t* be the distance to which the body would go along the tangent VQ in the time T, and join *t*C. Let this be supposed done for every point of the curve. Let *aik* and *axy* be two curves so related to the curve VIK, that the ordinate DF cuts off an area V*ai*D equal to the orbital sector VCI, and an area V*ax*D equal to the circular sector VCX.

Then, because the velocity of projection is given, the

Of Deflecting Forces.

distance Vt is known, and the area of the triangle VCt. But this is equal to the area VCI, by the laws of central forces. (No. 115.) Therefore the area $VaiD$ is given. Also, because the area VCI increases in the proportion of the time, the area $VaiD$ increases at the same rate.

Fig 28.



Therefore, having these subsidiary curves aik, axy, the problem is solved as follows:

Draw an ordinate Di, cutting off an area $VaiD$ proportional to the time, and describe a circle DIR. Then draw a line CX, cutting off a sector VCX, equal to the area $VaxD$ cut off by the ordinate Dix. This line will cut the circle DR in the point I, which is the point of the orbit that was demanded.

But the chief difficulty of the problem consists in the description of the two subsidiary curves aik and axy, into which the lines VIK and VXY are transformed. We attain this construction by resolving the motion in the arch of the orbit into two motions, one of which is in the direction of the transverse force, or of the radius vector, and the other is in the direction of revolution, or perpendicular to the radius.

Let Vk and IK be two very small arches described in equal moments, and therefore ultimately in the ratio of the velocities in V and I (No. 73). Describe the circle KE, cutting IC in N. Draw KC and kC, and kn perpendicular to VC.

The element ICK of the orbit is $= \frac{IC \times KN}{2}$, or to $\frac{1}{2}$ IC $\times$ KN. This is equal to the element $DikE$ of the area $VaiD$, or to $Di \times DE$, or to $Di \times IN$. Therefore $IN : KN = \frac{1}{2} IC : Di$, or $2IN : KN = IC : Di$, and $Di = \frac{IC \times KN}{2IN}$.

Now let $Alfgh$ be the exponent of the velocities, that is (No. 86), let Vl^2 be to Df^2 as ABLV to ABFD, or $Vl : Df = \sqrt{ABLV} : \sqrt{ABFD}$. Make Vv and Ii in the tangents respectively equal to Vl and Df. Draw vu and iO perpendicular to VC and IC, and vm perpendicular to LV produced. Let mrz be an equilateral hyperbola, having VC, ZC, for its asymptotes, and cutting FD produced in r. Then the ordinates Vm, Dr, are inversely proportional to CV, CD, or $Vm : Dr = CD : CV$, $= CI : CV$. But because the momentary sectors VCk and ICK are equal, $kn : KN = CI : CV$. Therefore,

$$Vm : Dr = kn : KN;$$
$$\text{but } Vv : Vm = Vk : kn,$$
$$\text{and } Ii \text{ (or } Df) : Vv = IK : Vk,$$
$$\text{therefore } Ii : Dr = IK : KN;$$
$$\text{but } Ii : iO = IK : KN, \text{ by sim. triang.}$$
$$\text{therefore } Dr = iO, \text{ and } iO : Vm = VC : CI.$$

Also, by similarity of triangles, $IO : iO = IN : KN$, and $2IO : iO = 2IN : KN$.

Now it was shown, that in order that the space $DikE$ may be equal to the space ICK, we must have

$$2IN : KN = IC : Di,$$
$$\text{or } 2IO : iO = IC : Di;$$
$$\text{but } iO : Vm = VC : IC,$$
$$\text{therefore } 2IO : Vm = VC : Di,$$
$$\text{and } Di = \frac{VC \times Vm}{2IO}.$$

Having obtained Di, we easily get Dx; for the ultimate ratio of ICK to XCY is that of IC^2 to VC^2. Therefore make

$$IC^2 : VC^2 = Di : Dx.$$

Thus are the points of the two subsidiary curves aik, axy, determined.

The rectangle $VC \times Vm$ is a constant magnitude, and is given because VC is given, and Vm is the given velocity Vl, diminished in the ratio of radius to the sine of the given angle CVQ.

But the line 2IO is of variable magnitude; but it is also given by means of known quantities. IO^2 is $= Ii^2 - iO^2$, $= Df^2 - Dr^2$, and $IO = \sqrt{Df^2 - Dr^2}$. Moreover, $Df^2 = ABFD$, and $Dr^2 = \frac{VC^2 \times Vm^2}{IC^2}$. Therefore $2IO =$ $2\sqrt{ABFD - \frac{VC^2 \times Vm^2}{IC^2}}$, expressed in known quantities, because ABFD is known from the nature of the centripetal force.

Let the indeterminate distance CI or CD be $= x$, and let the ordinate DF, expressing the force, be y. Let VC be a, and Vm be c, and let ab be a rectangle equal to the whole area of the exponent of force lying between the ordinate AB and the ordinate CZ, so that $ba - \int y dx$ may represent the indeterminate area ABFD.

$$\text{We have } Di = \frac{ac}{2\sqrt{ab - \int y dx - \frac{a^2 c^2}{x^2}}}$$

$$\text{and } Dx = \frac{a^3 c}{2x^2 \sqrt{ab - \int y dx - \frac{a^2 c^2}{x^2}}}.$$

Remark.—We have hitherto supposed that the velocity of projection is acquired by acceleration along AV. But this was merely for greater simplicity of argument, and that the final values of Di and Dx might be easier conceived. In whatever way the velocity is acquired, it will still be true, that when in any point V we make Vl to Vm as the momentary increment Vk of the arch is to the perpendicular kn on the radius vector, we shall have in every other point, such as I, the line Df to the line Dr as the increment IK of the arch to KN. And in the final equation Df will still be expressed by $\sqrt{ab - \int y dx}$.

126. *Cor.* 1. The angle which the path of the projectile makes with the radius vector is determined by this solution; for Ii is to iO as radius to the sine of this angle; which sine is therefore $= \frac{ac}{x\sqrt{ab - \int y dx}}$.

127. *Cor.* 2. When the magnitude $\frac{ac}{x}$ is equal to $\sqrt{ab - \int y dx}$, the path is perpendicular to the radius vec- Apsides determined;

Of Deflecting Forces.

tor, and the body is at one of the apsides of its orbit, and begins to recede from the centre after having approached to it, or begins to approach after having receded.

and curvature.

128. *Cor.* 3. The curvature of the orbit VIK is also determined in every point; for the curvature of any line is inversely as the radius of the equicurve circle, and this is to the chord which passes through C as radius to the sine of the angle CI*i*. Because the velocity in any point I is $= \sqrt{\text{ABFD}}$, and is equal to what the centripetal force at I would produce, by impelling the body along one fourth of the deflective chord of the equicurve circle, we have this chord $= 4\frac{\text{ABFD}}{\text{DF}}$. Or we obtain it by taking a third proportional to the momentary deflection and the momentary arch of the curve, or by other processes of the higher geometry, all proceeding on the quantities furnished in this investigation.

Newton the inventor.

129. Such is the solution of this celebrated problem given by Sir Isaac Newton, who may justly be called the inventor of the science of which it is the chief result, as well as of the geometry by help of which it is prosecuted. For we cannot give this glory to Galileo; for his simple problem of the motion of bodies affected by uniform and parallel gravity, however just and elegant his solution may be, was peculiar; and the same must be said of Mr Huygens's doctrine of centrifugal forces. Besides, these theorems had been investigated by Newton several years before, *suâ mathesi facem preferente*, as corollaries which he could not pass unnoticed, from his general method. This is proved by letters from Huygens. Newton's investigation is extremely but elegantly concise, and is one of the best exertions of his sagacious mind.

History of this problem.

130. Whether we consider this problem as a piece of mere mathematical speculation, or attend to its consequences, which include the whole of the celestial motions in all their extent and complication, we must allow it to be highly interesting, and likely to have engaged much attention in the period of ardent inquiry which closed the last century. Accordingly, it was no sooner known, by the publication of the *Mathematical Principles of Natural Philosophy* in 1686, than it occupied the talents of the most eminent mathematicians; and many solutions were published, some of which differ considerably from Newton's, and some are more expeditious, and better fitted for computation. Of these, the most remarkable for originality and ingenuity are those of De Moivre, Hermann, Keill, and Stewart. The last differs most from the methods pursued by others. M'Laurin's propositions on this subject, and in that part of his fluxions which treats of curvature, are highly valuable, classing the chief affections of curvilineal motions geometrically, as they are suggested by the fluxionary method; and then showing, in a very instructive manner, the connection between these mathematical affections of motion and the powers of nature which produce them. This part of his excellent work is a fine example of the real nature of all inquiries in dynamics, showing that it differs from geometry little more than in the language, in which the word *force* is substituted for *acceleration*, *retardation*, or *deflection*. We recommend the careful perusal of these propositions to all who wish to have clear conceptions of the subject. Dr John Keill and Dr Horsley (bishop of Rochester) have given particular treatises on the motions of bodies deflected by centripetal forces inversely proportional to the cubes of the distances; induced by the singular motions which result from this law of action, and the multitude of beautiful propositions which they suggest to the mathematician. Newton, indeed, first perceived both of these peculiarities, and has begun this branch of the general problem. He first demonstrated the description of the logarithmic and hyperbolic spirals, and indicated a variety of curious recurring elliptical spirals, which would be described by means of this force, showing that they are all susceptible of accurate quadrature. Several of those authors affect to consider their solutions as more perfect than Newton's, and as more immediately indicating the remarkable properties of such motions; and also affect to have deduced them from different and original principles. But we cannot help saying that their claims to superiority are very ill founded; there is not a principle made use of in their solutions which was not pointed out by Newton, and employed by him. The appearance of originality arises from their having taken a more particular concern in some general property of curvilineal motions, such as the curvature, the centrifugal force, &c. and the making that the leading step of their process. But Newton's is still the best, because it is strictly elementary, aiming at the two leading circumstances, the motion to or from the centre, and the motion of revolution round that centre. To these two purposes he adapted his two subsidiary curves.

Singular boast of John Bernoulli.

131. Is it not surprising, that, twenty-five years after the publication of Newton's *Principia*, a mathematician on the Continent should publish a solution in the Memoirs of the French Academy, and boast that he had given the first demonstration of it? Yet John Bernoulli did this in 1710. Is it not more remarkable that this should be precisely the solution given by Newton, beginning from the same theorem, the 40th I. *Prin.* following Newton in every step, and using the same subsidiary lines? Yet so it is. Bernoulli actually reduces the whole to two functions, namely,

$$\frac{ac}{\sqrt{ab-\int\varphi dx-\frac{a^2c^2}{x^2}}} \text{ and } \frac{a^2c}{\sqrt{abx^4-x^4\int\varphi dx-a^2c^2x^2}};$$

which last is plainly the same with Newton's

$$\frac{\text{Q}\times\text{CX}^2}{\text{A}^2\sqrt{\text{ABDF}-\text{Z}^2}};$$

because Newton's $\frac{\text{Q}}{\text{A}}$ is the same with $\frac{ac}{x}$, and Newton's $\text{A}^2\sqrt{\text{ABFD}-\text{Z}^2}$ is the same with

$$x^2\sqrt{ab-\int\varphi dx-\frac{a^2c^2}{x^2}},$$

which Bernoulli has changed into

$$\sqrt{abx^4-x^4\int\varphi dx-a^2c^2x^2}.$$

Bernoulli's chief boast in this dissertation is, that *now* philosophers may be assured that the planets will always describe conic sections; a truth of which they had not as yet received any proof; because, says he, Newton's argument for it in the corollary of the 13th proposition is inconclusive, and because he had not been able to accommodate his demonstration of the 41st and 42d propositions to the particular case of the planetary gravitation. Newton's demonstration in the corollary of the 13th proposition is just founded on the principle on which the very demonstration of the 42d, adopted by Bernoulli, proceeds, and without which that demonstration is of no force; namely, that a body, in given circumstances of situation, velocity, direction, and centripetal force, can describe no other figure than what it really describes. Newton did not accommodate the demonstration of the 42d proposition to the planetary motions, because he had already demonstrated the nature of their orbits; but mentions the case of a force proportional to the reciprocal of the cubes of their distance, not as a deduction from the 42d, but because it *was not* a deduction from it, and admitted a very singular and beautiful investigation by methods totally and essentially different.

Conclusion.

132. It cannot be expected that, in the narrow limits prescribed to a work like ours, we can proceed to consider the various departments of this celebrated problem. We are only giving the outlines of the general doctrines of dynamics; and we have bestowed more time on those which are purely elementary than some readers may think they deserve. We were anxious to give just conceptions of the fundamental principles of dynamics; because we know that nothing else can entitle it to the name of a demonstrative science, and because we see much indistinctness and uncertainty, and a general vagueness or want of precision, in several elementary works which are put into the hands of persons entering on the study. This leads to errors of more consequence than a person is apt to think; because they affect our leading thoughts of mechanism itself, and our notions of the intimate nature of the visible universe.

Universal re-action is a law of the material world.

133. But we must conclude the article with this great problem. Many very general doctrines of dynamics remain untouched; all, namely, that relate to the rotative motion of rigid bodies, and all that relate to the mutual action of bodies on each other in the way of impulse.

Notwithstanding these great omissions, we must observe that no new principle remains to be considered. We have given all that are necessary; and there is no question that occurs in the cases omitted which cannot be completely answered by means of the propositions already established. We have taught how to discover the existence and agency of a mechanical force, to measure and characterize it, and then to state what will be its various effects, according to the circumstances of the case.

134. Proceeding by these principles, men have discovered an universal fact, that every *action* of one body on another is accompanied by an equal *re-action* of that other on the first in the opposite direction; that is, to express it in the language of dynamics, "all the phenomena which make us infer that the body A possesses a force by which it changes the motion of the body B, show, at the same time, that B possesses a force by which it makes an equal and opposite alteration in the motion of A." This, however, is not a doctrine of abstract dynamics; it does not flow from our idea of force; therefore it was not included in our list of the *laws of motion.* It is a part of the mechanical history of nature, just as the law of universal gravitation is; and it might be called the law of *universal re-action.* Sir Isaac Newton has, in our humble apprehension, deviated from his accustomed logical accuracy, when he admits, as a third *axiom* or law of motion, that re-action is always equal and contrary to action. It is a physical law, in as far as it is *observed* to obtain through the whole extent of the solar system. But Newton himself did not, in the subsequent part of his noble work, treat it as a logical axiom; that is, as a law of human thought with respect to motion; for he labours with much solicitude, and with equal sagacity, to prove, by *fact and observation,* that it really obtains through the whole extent of the solar system; and it is in this discovery that his chief claim to unequalled penetration and discernment appears.

Impulsion explained by it,

135. Availing ourselves of this fact, we, with very little trouble, state all the laws of impulsion. The body A, for example, moving to the westward at the rate of eight feet per minute, overtakes the double body B, moving at the rate of four feet per minute. What must be the consequence of their impenetrability, and of the equality and contrariety of action and re-action? Their motions must be such that both sustain equal and opposite changes. They must give, in some way or other, *this* indication of possessing equal and opposite forces. This will be the case if, when the changes are completed, A and B move on in contact at the rate of four feet per minute; for here A has produced in each half of B a change of motion two, and therefore a totality of change equal to four. This is the effect, the mark, the measure of the *impulsive* force of A; for it is the whole *impulsion.* B has produced in A a change of motion four, equal to the former, and in the opposite direction. This is the effect, mark, and measure of the *repulsive* force of A; for it is the whole *repulsion.* And this is all that we observe in the collision of two lumps of clay; and the observation is one of the facts on which the reality of the physical law of equal action and re-action is founded; and we can make no further inference from *this* fact.

But the event might have been very different. A and B may be two magnets floating on corks on water, with their north poles fronting each other. We know, by other means, that they really possess forces by which they equally repel each other. The dynamical principles already established tell us also what must happen in this case. That both conditions of equal re-action and sensible repulsion may be fulfilled, A must come to rest, and B must move forward at the rate of four feet per minute. The same thing must happen in the meeting of perfectly elastic bodies, such as billiard balls. If elasticities are known to be imperfect in any degree, our dynamical principles will still state the effect of their collision in conformity to the law of equal reaction.

and rotation.

136. In like manner, all the motions of rotation are explained or predicted by means of the same principles of dynamics applied to the force of cohesion. This is considered as a moving force, because, when the attraction of a magnet acts on a bit of iron attached to one end of a long lath floating on water, the whole lath is moved, although the magnet does not act on it at all; some other force acts on it; it is its cohesion, which is therefore a moving force, and the subject of dynamical discussion.

137. And thus it appears that these subjects do not come necessarily, nor perhaps with scientific propriety, under the category of dynamics, but are parts of the mechanical history of nature. Yet, did a work like ours give room in this place, the study of mechanical nature might be considerably improved, by giving a system of such *general* doctrines as involve no other notions but those of force and its measures, and the hypothesis of equal re-action. Some very general, nay universal, consequences of this combination might be established, which would greatly assist the mechanician in the solution of difficult and complicated problems. Such is the proposition, that *the mutual actions of bodies depend on their relative motions only, and require no knowledge of their real motions.* This principle simplifies in a wonderful manner the most difficult and the most frequent cases of action which nature presents to our view; but at the same time gives a severe blow to human vanity, by forcing us to acknowledge that we know nothing of the real motion of any thing in the universe, and never shall know any thing of it, till our intellectual constitution, or our opportunities of observation, are completely changed.

138. M. d'Alembert had made this principle still more serviceable for extricating ourselves from the immense complication of actions that occurs in all the spontaneous phenomena of nature, by presenting it to us in a different form, which more distinctly expresses what may be called the *elements* of the actions of bodies on each other. His proposition is as follows (see his *Dynamique,* page 73):

D'Alembert's general principle of dynamics.

"In whatever manner a number of bodies change their motions, if we suppose that the motion which each body would have in the following moment, if it were perfectly free, is decomposed into two others, one of which is the motion which it really takes in consequence of their mutual actions, the other will be such, that if each body were

impressed by this force alone (that is, by the force which would produce this motion), the whole system of bodies would be in equilibrio."

This is almost self-evident; for if these second constituent forces be not such as would put the system in equilibrio, the other constituent motions could not be those which the bodies really take by the mutual action, but would be changed by the first.

For example, let there be three bodies P, Q, R, and let the forces A, B, C, act on them, such as would give them the velocities p, q, r, in any directions whatever, producing the momenta, or quantities of motion, $P \times p$, $Q \times q$, $R \times r$, which we may call A, B, C, because they are the proper measures of the moving force. Let us moreover suppose, that, by striking each other, or by being any how connected with each other, they cannot take these motions, A, B, and C, but really take the motions a, b, and c. It is plain that we may conceive the motion A impressed on the body P, to be composed of the motion a, which it really takes, and of another motion α. In like manner, B may be resolved into b, which it takes, and another β; and C into c and $\varkappa$. The motions will be the same, whether we act on P with the force A, or with the two forces a and α; whether we act on Q with the force B, or with b and β; and on R with the force C, or with c and $\varkappa$. Now, by the supposition, the bodies actually take the motions a, b, and c; therefore the motions α, β, and $\varkappa$, must be such as will not derange the motions a, b, and c; that is to say, that if the bodies had only the motions α, β, and $\varkappa$, impressed on them, they would destroy each other, and the system would remain at rest.

M. d'Alembert has applied this proposition with great address and success to the very difficult questions that occur in the motions and actions of fluids, and many other most difficult problems, such as the precession of the equinoxes, &c. The cause of its utility is, that in most cases it is not difficult to find what forces will put a system in equilibrio; and, combining these with the known extraneous forces whose effects we are interested to discover, we obtain the motions which really follow the mutual action of the bodies.

This is not, properly speaking, a principle; it is a form in which a general fact may be conceived. In the same way the celebrated mathematician De la Grange observed, that a system of bodies, acting on each other in any way, is in equilibrio, if there be impressed on its parts forces in the inverse proportion of the velocities which each body takes in consequence of their action or connection; and he expresses this universal fact by a very simple formula; and, calling this also a principle, he solves every question with ease and neatness, by reducing it to the investigation of those velocities. In this way he has written a complete system of dynamics, to which he gives the title of *Méchanique Analytique*, full of the most ingenious and elegant solutions of very interesting and difficult problems; and all this without drawing a line or figure, but accomplishing the whole by algebraic operations.

But this is not teaching mechanical philosophy; it is merely employing the reader in algebraic operations, each of which he perfectly understands in its quality of an algebraic or arithmetical operation, and where he may have the fullest conviction of the justness of his procedure. But all this may be (and, in the hands of an expert algebraist, it generally is), without any notions, distinct or indistinct, of the things or the process of reasoning that are represented by the symbols made use of. (J. R.)

DYNAMOMETER, an instrument for ascertaining the relative strength of men and horses. An ingenious instrument of this kind was invented in London about the middle of the last century by the celebrated mechanician Graham, and improved by Desaguliers. It was constructed of woodwork however, and was soon found to be too complicated and cumbrous to be of any general utility. A simpler instrument was that invented by Leroy of the French Academy. It consisted of a metal tube ten or twelve inches in length, placed vertically on a foot like that of a candlestick, and containing in the inside a spiral spring, having above it a graduated shank terminating in a globe. This shank, together with the spring, sunk into the tube in proportion to the weight acting upon it, and thus pointed out, in degrees, the strength of the person who pressed on the ball with his hand. Simpler and more ingenious than either of these however is that of Régnier, of which a detailed description will be found in the *Journal de l'Ecole Polytéchnique*, tom. ii.

This dynamometer, in its form and size, has a near resemblance to a common graphometer. It consists of a spring twelve inches in length, bent into the form of an ellipsis; from the middle of which arises a semicircular piece of brass, having engraved upon it the different degrees that express a force of the power acting on the spring. The whole of this machine, which weighs only two pounds and a half, opposes, however, more resistance than may be necessary to determine the action of the strongest and most robust horse.

DYRRHACHIUM, in *Ancient Geography*. See EPIDAMNUS, and DURAZZO.

DYSÆ, in *Scandinavian Mythology*, inferior goddesses, whose province it was to convey the souls of such as died in battle to the abode of Odin, which was called *Valhalla* or the hall of slaughter, where they were to drink, with him and their other gods, in cups formed of the skulls of their enemies, a kind of malt liquor called *cerevisia*. The *Dysæ* conveyed those who died a natural death to *Hela*, the goddess of hell, where they were tormented with hunger, thirst, and every kind of evil.

DYSART, a royal burgh and seaport-town of Scotland, county of Fife, situated on the north coast of the Firth of Forth, 12 miles N. by E. of Edinburgh. It consists chiefly of three narrow streets, with a species of square in the centre. In the principal or High street are a number of antique houses, the fronts of which are generally decorated with inscriptions and dates. Dysart House, the residence of the Earl of Rosslyn, is on the west side of the town. Dysart is a place of great antiquity, being mentioned so early as 874, when the Danes invaded Fife. It was made a royal burgh in the reign of James V. The trade of Dysart was formerly very considerable, and acquired for it the name of "Little Holland;" but it is now unimportant, the chief exports being coal. The harbour of the town is tolerably good,—and has attached to it a wet-dock. The weaving of checks and ticks constitute the chief employment of the inhabitants. It unites with Kirkcaldy, Burntisland, and Kinghorn, in returning a member to parliament. Pop. (1851) of municipal burgh 1610; of parliamentary burgh 8041.

DYSCRASY, among physicians, denotes an ill habit or state of the humours, as in the scurvy, jaundice, &c.

DYSENTERY, a diarrhœa or flux, in which the stools are mixed with blood, and the bowels severely griped.

DYSOREXY, a want of appetite; or a bad and depraved appetite.

DYSPEPSIA, a difficulty of digestion.

DYSPNŒA, a difficulty of breathing.

DYVOUR (Fr. *devoir*), in *Scotch Law*, an insolvent debtor; a bankrupt who has made a *cessio bonorum* to his creditors.

E.

E, the second vowel, and fifth letter of the alphabet. This letter is most probably derived from the old character in the ancient Hebrew and Phœnician alphabets, reversed by the Greeks to this position, E, not from the Hebrew ה, as some have supposed. From the same origin is also derived the Saxon *e*, which is the first letter in their alphabet that differs from the Latin one. It is formed by a narrower opening of the larynx than the letter A; but the other parts of the mouth are used nearly in the same manner as in that letter. E has a long and short sound in most languages. The short sound is audible in *bed, fret, den*, and other words ending in consonants; the long sound is produced by a final *e*, or an *e* at the end of words, as in *glebe, here, hire, scene, sphere, interfere, revere, sincere*, and the like, in most of which it sounds like *ee*. In some other cases, this letter, by coming after *i*, is long, as in *believe, chief, grief, reprieve;* and sometimes the long sound is expressed by *ee* as in *bleed, beer, creed*, and so on. Sometimes the final *e* is silent, and only serves to lengthen the sound of the preceding vowel, as in *rag, rage, stag, stage, hug, huge*. The sound of *e*, however, is obscure in the following words: *oxen, heaven, bounden, fire, massacre, maugre*, and other words. The Greeks have their long and short *e*, which they call *epsilon* ε, and *éta* η. The French have several kinds of *e;* the Latins have likewise a long and short *e*. In some instances the latter also write *e* instead of *a*, as *dicem* for *dicam;* and this is no doubt the reason why *a* is so often changed into *e* in the preter-perfect tense, as *ago, egi; facio, feci*, and the like.

As a numeral, E stands for 250, according to the verse,

E, quoque ducentos et quinquaginta tenebit.

In the calendar it is the fifth of the dominical letters; and in sea charts it distinguishes all the easterly points. In ancient contractions and abbreviations E represents *Est, Ennius, Edilis;* EB, *Ejus Bona;* ED, *Ejus Domus;* EE, *Ejus Ætas;* EF, *Ejus Filius;* and so on.

EACHARD, John (1636–1697), an English divine, and the author of *The Grounds and Occasions of the Contempt of the Clergy and Religion inquired into*, 1670. In 1675 he succeeded Lightfoot as master of Catharine Hall. He also wrote against the philosophy of Hobbes. A collected edition of his works was published in 1774.

Eachard, *Laurence*, an English historian, and nearly related to the preceding, was born in 1721 at Suffolk, where his father was a clergyman. He was educated in the university of Cambridge; and after taking orders was presented to the living of Welton and Elkington in Lincolnshire. He was subsequently archdeacon of Lincoln, and prebendary of Stowe. He died in 1730. The work by which he is best known is his *History of England*, in two parts, from the time of the Roman Invasion to the Revolution. It has been attacked by Calamy and Oldmixon; but though it reached several editions, it is now almost entirely forgotten. He wrote also an *Ecclesiastical History from the Nativity of Christ to Constantine;* a *History of Rome till Augustus;* a *History of the Revolution*, and several other works.

EADMERUS, Eadmer, or Edmer, an English historian of the twelfth century. The place of his birth is unknown. His taste for history was developed at an early age; and when a monk in the cathedral of Canterbury he became the bosom friend of St Anselm and his successor Ralph. To the former of these he was appointed spiritual director by the pope. In 1120 he was sent for by Alexander I. of Scotland, to be raised to the primacy of that kingdom; and having obtained leave of Henry and the Archbishop of Canterbury, he departed for Scotland, where he was kindly received by the king, and on the third day after his arrival elected bishop of St Andrews. On the day after his election, however, a dispute arose in regard to the ceremony of consecration; Eadmer refusing to be consecrated by any but the Archbishop of Canterbury, whom he believed to be primate of all Britain; and Alexander with equal pertinacity maintaining that the see of Canterbury had no pre-eminency over that of St Andrews. This breach between the king and the bishop-elect became daily wider, until at length Eadmer, despairing of recovering the royal favour, sent his pastoral ring to the king, laid his pastoral staff upon the high altar, and abandoning his bishopric, returned to England. He was kindly received by the Archbishop and clergy of Canterbury, though they disapproved of his stiffness; and being deprived of their sympathy, Eadmer soon repented of his impetuosity, and endeavoured to retrace his steps. With this view he wrote a long submissive letter to the king of Scotland in 1122, entreating his permission to return to the bishopric, and promising compliance with his royal pleasure in everything respecting his consecration. These overtures, however, did not produce the desired effect. The fame of Eadmer accordingly rests solely on his historical works, particularly on his History of the Affairs of England in his own Time, from 1066 to 1122; a work in which he has inserted many original papers, and preserved many important facts which are nowhere else to be found. This production has been highly commended for its authenticity, as well as the regularity of its composition and purity of its style. It is indeed more free from legendary tales than any other work of this period; and it is impossible to peruse it with attention without conceiving a favourable opinion of the learning, good sense, sincerity, and candour of its author. Eadmer wrote also the Lives of St Anselm, St Wilfred, St Dunstan, and others. The best edition of his History is that by Selden in 1623.

EAGLE. See Ornithology.

Eagle, in *Heraldry*, is accounted one of the most noble bearings in armoury, and, according to the learned in this science, ought to be given to none but such as greatly excel in the virtues of generosity and courage, or have rendered singular service to their sovereigns; in which case they may be allowed a whole eagle, or an eagle naissant, or only the head or such other parts as may be judged most suitable to their exploits.

The eagle has been borne as an ensign or standard by several nations. The first who seem to have assumed the eagle were the Persians, according to the testimony of Xenophon; but subsequently it was adopted by the Romans, who, after a great variety of standards, at length fixed on the eagle, in the second year of the consulate of C. Marius, having till that period used indifferently wolves, leopards, and eagles. The Roman eagles were figures in relief formed of silver or gold, and borne on the tops of pikes; the wings being displayed, with frequently a thunderbolt in the talons. Under the eagle on the pike were piled bucklers, and sometimes crowns.

Constantine is said to have been the first who introduced the eagle with two heads, to intimate, that though the empire seemed divided, it had yet only one body. Others say that it was Charlemagne who resumed the eagle as the Roman ensign, and added to it a second head; but that opinion is destroyed by an eagle with two heads observed by Lipsius on the column of Antoninus, as also by the eagle's having only one head on the seal of the golden bull of the Emperor Charles IV. The conjecture, therefore, of Menestrier appears more probable; namely, that the emperors of the East, when there were two on the throne at the same

time, struck their coins with the impression of a cross with a double traverse, which each of them held in his hand, as being the symbols of the Christians; and that they did the like with the eagle in their ensigns, and, instead of doubling, joined them together, representing them with two heads; a practice in which they were followed by the emperors of the West. But this conjecture of Menestrier is not confirmed by ancient coins, without which Papebroche inclines to think the use of the eagle with two heads to have been merely arbitrary, though he admits it to be probable that it was first introduced on occasion of there being two emperors on the same throne.

The eagle on medals is, according to Spanheim, a symbol of divinity and providence, and, according to all other antiquaries, of empire. The princes on whose medals it is most usually found are the Ptolemies, and the Seleucidæ of Syria. An eagle with the word *consecratio* expresses the apotheosis of an emperor.

Eagle (*Aquila*), a constellation. See Astronomy.

White Eagle, a Polish order of knighthood, instituted in 1325 by Vladislaus V. on marrying his son Casimir to a daughter of the grand duke of Lithuania. The badge was a gold chain to which was suspended a silver eagle crowned.

Black Eagle, an order of knighthood, instituted in 1701 by the elector of Brandenburg, on his being crowned king of Prussia. The badge was an orange-coloured ribbon sustaining a black eagle.

Eagle, in *Numismatics*, a sort of base money which was current in Ireland in the early part of the reign of Edward I., that is, about the year 1272. There were also lionines, rosades, and many other coins of the same sort, named according to the figures with which they were impressed. The current coin of the kingdom at that time was a composition of copper and silver, in determinate proportions; but these were so much inferior to the standard of that time, that they were not intrinsically worth half so much as the others. They were imported from France and other foreign countries. When Edward had been a few years established on the throne, he set up mints in Ireland for coining good money, and then prohibited the use of eagles, and other kinds of base coin; making it death, with confiscation of effects, to import any more of them into the kingdom. Eagle is the designation of the principal gold coin of the American United States.

Eagle-Stone. See Ætites.

EALDERMAN, or Ealdorman, among the Saxons, was of the same import with *Earl* among the Danes. The word was also used for an elder, senator, or statesman; and hence, at this day, those functionaries are called *aldermen* who are associates to the chief officer in the common council of a city or corporate town.

EAR. See Anatomy.

Ear is used technically in music to denote susceptibility of the auditory organ, as well as of the mind, to all musical impressions; or the faculty of perceiving them correctly, and the power of transmitting them unchanged to the sensorium. When speaking figuratively of *an ear, a good ear, a fine ear* for music, we mean an ear very sensitive to music—able to distinguish true intonation from false—to perceive accuracy of time and justness of harmony—to feel the beauties of a musical composition and discover its faults, &c. To have *no ear* for music implies the absence of all these powers. An ear for the measure and cadence of poetical versification and for rhyme, by no means necessarily implies an ear for music, although both may and often do co-exist. Some distinguished poets have been utterly destitute of musical ear; while others, such as Milton, possessed great musical susceptibility. The want of an ear for music is a defect as inscrutable as that peculiarity of eye in some persons which hinders them from distinguishing colours. See Music, § *The sense of hearing*. (G. F. G.)

EARING, in nautical language, a rope attached to the cringle of a sail, by means of which it is bent or reefed.

EARL, a British title of nobility, next below a marquis, and above a viscount. The title is one of great antiquity, and the word is evidently a corruption of the Norwegian *jarl*. A certain order of the Saxon nobility was called *ealdormen*, elder men, a word of the same signification with *senior* or *senator* among the Romans; and also *schiremen*, because they had each of them the civil government of a civil division or shire. On the irruption of the Danes they changed the names to *eorels*, which, according to Camden, had the same signification in their language. In Latin they are called *comites*, (a title first used in the empire), from being the king's attendants; *a societate nomen sumpserunt, reges enim tales sibi associant*. After the Norman Conquest they were for some time called *counts*, from the French; but they did not long retain that name themselves, though their shires are thence denominated *counties* to this day. It is now become a mere title, the holders of which have nothing to do with the government of the county, that being now entirely devolved on the sheriff, the earls-deputy or *vicecomes*. In writs, commissions, and other formal instruments, the sovereign, when mentioning any peer of the degree of an earl, usually styles him trusty and well-beloved cousin; an appellation as ancient as the reign of Henry IV., who being, either by his wife, his mother, or his sisters, actually related or allied to every earl in the kingdom, artfully and constantly acknowledged that connection in all his letters and other public acts; whence the usage descended to his successors, though the reason has long ago failed.

Earl-*Marshal*. See Marshal.

EARNEST (Arrhæ), something given to bind a bargain; generally a small sum of money. By the civil law, he who recedes from his bargain loses his earnest; and if the person who received the earnest resiles, he must return the earnest double. But with us, the person who gives it is in strictness obliged to abide by his bargain; and in case he decline it, he is not discharged upon forfeiting his earnest, but may be sued for the whole money stipulated.

EAR-RING, an ornament worn at the ear; a pendant or jewel suspended by means of a ring or a hook passing through the pendulous lobe of the ear. The use of this kind of ornament dates from the remotest antiquity, since the first mention of ear-rings occurs in the book of Genesis. Ear-rings of certain kinds were anciently, and still are, in the East, instruments or appendages of idolatry and superstition—being regarded as talismans and amulets. Such, probably, were the ear-rings of Jacob's family, which he buried with the strange gods at Bethel. This somewhat barbarous species of adornment was used (as it still is in some countries) by both sexes among many Oriental nations; especially by the Lydians, Persians, Babylonians, Libyans, and Carthaginians, as may be gathered from various ancient authors.

Among the Hebrews and the Egyptians their use appears to have been confined to women: but that they were extensively used by the men of various other nations is sufficiently proved by the Egyptian monuments.

Among the Greeks and Romans ear-rings were worn only by females, and were sometimes of enormous value. It is a curious fact that the ears of the Venus de' Medici, and of some other female statues, are pierced, as if for the purpose of bearing these appendages.

EARTH (Sax. *eard, eorth, yrth*), among ancient philosophers, one of the four elements of which the whole system of nature was believed to be composed. In *Astronomy* and *Geography*, it denotes one of the primary planets, being the terraqueous globe we inhabit. See Astronomy; Figure of the Earth; Geology; Physical Geography.

EARTHENWARE. See Pottery.

EARTHQUAKE. The proximate cause of earthquakes, though by no means accurately defined, seems referable to the action of internal heat or fire. That the earth was once subject to the action of a vast internal power springing probably from the development of subterranean or central heat, the elevations and depressions, and the generally scarred and torn character of its exterior, make sufficiently evident. A power similar in kind, but more restricted in degree, is still at work in the bowels of the earth, and occasionally breaks down all barriers and devastates certain parts of the world. There is good reason for holding that earthquakes are closely connected with volcanic agency. Both probably spring from the same cause; and may be regarded as one mighty influence operating to somewhat dissimilar results. Volcanic agency, therefore, is an indication of earthquakes, and traces of the first may be taken as indications of the existence (either present or past, actual or possible) of the latter.

The manifestation of these awful phenomena is restricted in its range. Accordingly, geologists have laid down certain volcanic regions or bands within which this manifestation takes place. Over these regions various traces of volcanic agency are found, such as either gaseous vapours or hot springs, or bituminous substances, and in some instances (occasionally) active volcanoes. See PHYSICAL GEOGRAPHY, sec. v.; ÆTNA; ANTIOCH; LISBON; &c.

EARTHS, in *Chemistry*. See CHEMISTRY.

EASDALE, a small island of Argyleshire, 10 miles S.S.W. of Oban; noted for its slate-quarries, which have been wrought for 150 years.

EASE, in seamen's language, is to slacken a rope. To *ease a ship* is to put the helm a-lee when she is sailing close-hauled.

EASEL, the portable frame on which painters place their canvas. Hence, *easel-pieces* are the smaller pictures which are painted on the easel, as distinguished from those which are drawn on walls, ceilings, &c.

EASINGWOLD, a market-town in the north riding of Yorkshire, 13 miles N.N.W. of York. A large market is held here every Friday, chiefly for butter, bacon, and agricultural produce from the vicinity. Pop. (1851) 2240.

EAST, one of the four cardinal points of the world, being that point of the horizon where the sun is seen to rise when in the equinoctial. The word *east* is Saxon. In Italy, and throughout the Mediterranean, the east wind is called the *levante;* in Greek, ἀνατολή and ἀπηλιώτης, because it comes from the side of the rising sun, ἀπ' ἡλίου; in Latin, *Eurus*.

EAST INDIA COMPANY. See INDIA.

EASTBOURNE, a village and watering-place on the coast of Sussex, 65 miles from London by the Brighton and South Coast railway. It is situated in a chasm between two cliffs; one of which, Beachy Head, is the loftiest headland on the English Channel. It is divided into three distinct parts, and is much resorted to for sea-bathing. Pop. of parish (1851) 3133.

EASTER, a festival of the Christian church, observed in memory of our Saviour's resurrection. The Greeks call it *pasga*, the Latins *pascha*, from a Hebrew word signifying *passage*, applied to the Jewish feast of the Passover. It is called *Easter* in English, from the goddess Eostre, who was worshipped by the Saxons with peculiar ceremonies in the month of April. The Asiatic churches kept their Easter upon the very same day on which the Jews observed their Passover, and others on the first Sunday after the first full moon in the new year. This controversy was determined in the council of Nice, when it was ordained that Easter should be kept upon one and the same day, which should always be a Sunday, in all Christian churches in the world. See CALENDAR, vol. vi., p. 86.

EASTON, the capital of the county of Northampton, state of Pennsylvania, N. America, is situated on the W. side of the Delaware river, which here receives the Lehigh 93 miles E.N.E. of Harrisburg. This is one of the most prosperous commercial towns in Pennsylvania, being the entrepôt of an extensive trade between the coal and iron fields of that state, and the terminus of several lines of railway and of canals. It has numerous churches and educational institutions; among the latter—Lafayette College, which in 1850 had a president, 7 professors, and 82 students. Pop. (1850) 7250. There are several other places of this name in the United States.

EASTPORT, the capital of Washington county, state of Maine, North America, is built on the Moose and several smaller islands in Passamaquaddy Bay, 183 miles W.N.W. of Augusta. Pop. (1850) 4125. It is a garrison town, and has a fine harbour and an extensive trade.

EAU DE COLOGNE, a well-known perfume, prepared in many different ways. The recipe of Jean Maria Farina may be found in Ure's *Dictionary of Arts*, but it appears to be needlessly complicated. A good imitation of the genuine Eau de Cologne may be thus prepared: To one pint of very pure alcohol add the following ingredients; oils of bergamot, rosemary, and orange-peel, of each 1 drachm; cardamom seeds, 1 drachm; orange-flower water, 1 pint; and distil off one pint from a water bath.

EAU *de Luce*, a compound formed of the distilled oil of amber and a strong solution of ammonia, to which some mastic and scent are usually added. The vaunted efficacy of this compound as a remedy for the bites of venomous reptiles, appears to reside solely in the ammonia it contains.

EAVES (Sax. *efese;* Fr. *eaux*), the lower edges of the inclined sides of a roof, which project beyond the face of the walls, so as to throw off rain from the foundations.

EAVES-*Dropper*, one who stands under the eaves, or near the wall or window of a house, for the purpose of hearing what passes within. Eaves-droppers are called by the *Stat. of West.* i. c. 33, "*evil members of the commonwealth.*" In England they are punishable by a fine.

EBDOMARIUS, or HEBDOMARIUS, is used in old ecclesiastical writings to denote an officer who was appointed weekly to superintend the performance of divine service in cathedrals, and prescribe the duties of each person officiating in the choir.

EBDOME, in *Antiquity*, a festival observed by the Spartans on the seventh day of every lunar month, in honour of Apollo, to whom all seventh days were sacred, because he was born on the seventh day of the month; and hence he was sometimes called *Ebdomagetes*.

EBERHARD, JOHANN AUGUSTUS, an eminent German theologian and philosopher, was born at Halberstadt, in Lower Saxony, Aug. 31, 1739. His father was the singing-master at the church of St Martin's in that town, and also teacher of the school of the same name; a man, it is said, of a lively disposition, and considerable literary attainments. Young Eberhard was educated partly at home and partly in the school above mentioned. In the seventh year of his age he repaired to the University of Halle, with the view of prosecuting his theological studies. Towards the end of 1759 he returned to his native town, and became tutor to the eldest son of the Baron Von der Horst, to whose family he attached himself for a number of years. In 1763 he was appointed con-rector of the school of St Martin's, and second preacher in the Hospital Church of the Holy Ghost; but he soon afterwards resigned these offices, and followed his patron to Berlin.

The advantages he enjoyed in this family, of being introduced into the best company, tended to polish his manners and to form, even at an early period, a style of writing which served as a model to many of his contemporaries. His residence at Berlin gave him an opportunity of extending his knowledge, and of cultivating the acquaintance of some of

the most eminent literary characters in Germany. Amongst these were Nicolai and Mendelssohn, with whom he associated upon terms of intimate friendship.

In 1768 he accepted the situation of preacher or chaplain to the workhouse at Berlin, along with that of preacher in the neighbouring fishing village of Stralow. The income from these livings was small; but his object was to continue at Berlin, and he had at the same time the promise of further preferment upon the first vacancy. He now applied with renewed ardour to the study of theology, philosophy, and history; and the first fruits of his talents and application soon appeared in his *New Apology of Socrates;* a work exhibiting such originality of thought and eloquence of style as at once established his character as a writer. This work was occasioned by an attack which was made on the sentiments contained in the fifteenth chapter of Marmontel's *Belisarius* by one Peter Hofstede, a clergyman of Rotterdam, who, with a misdirected industry, raked up the vices of the most celebrated characters in the pagan world, and even went so far as to maintain that the most virtuous amongst the heathen were no fit objects of divine mercy. He seemed particularly desirous to blacken the character of Socrates; and from this circumstance Eberhard was induced to give to his work the title which we have mentioned above. The greater part of it is occupied with an investigation of some of those peculiar doctrines which have been admitted as dogmas of the Christian church, upon the authority of some of the early fathers; and an examination of those texts of Scripture upon which they are founded. The *Apology* itself, which constitutes but a small part of the book, is esteemed a masterpiece of clear, dignified, and persuasive eloquence. The whole work exhibits much reading and philosophical reflection; but the liberality of his reasoning gave great offence to many of the strictly orthodox divines of his time, and is believed to have obstructed his preferment in the church.

In 1774 he was appointed to the living of Charlottenburg; and he employed the leisure he had in this situation in publishing a second volume of his *Apology;* in which he not only endeavours to obviate some objections which were taken to the former part, but continues his inquiries into the doctrines of the Christian religion, religious toleration, and the proper rules for interpreting the Scriptures. Perceiving that his further promotion in the church would be attended with difficulty, he resolved, although reluctantly, to accept the situation of professor of philosophy at the University of Halle, which became vacant in 1778 by the death of G. F. Moier. But, however excellent as a writer, and however just his ideas upon philosophical subjects, he does not appear to have been peculiarly qualified to excel as a teacher. He was highly esteemed, indeed, both by professors and students; but his lectures, although they attracted at first a considerable concourse, never acquired any degree of popularity. He continued, however, to lecture very regularly; and published several manuals for the use of his pupils.

On his arrival at Halle, the philosophical faculty presented him with a diploma as doctor in philosophy and master of arts. In 1786 he was admitted a member of the Berlin Academy of Sciences; and in 1805 the king of Prussia conferred upon him the honorary title of a privy-councillor. In 1808 he obtained the degree of doctor in divinity, which was given him as a reward for his theological writings. He married in 1778, but had no children. He died Jan. 6, 1809, being then in the seventieth year of his age.

Eberhard's attainments in philosophy and literature were extensive and profound. He was master of the learned languages, spoke and wrote French with facility and correctness, and understood English, Italian, and Dutch. He had read a great deal, was thoroughly versed in the philosophical sciences, and possessed a just and discriminating taste for the fine arts. He was a great lover of music, and was himself a proficient in that science. His manners were mild and unassuming; and his amiable and cheerful disposition, no less than his talents and virtues, endeared him to a numerous circle of friends.

The following is a list of his works:—*Neue Apologie des Socrates*, &c., 2 vols. 8vo, 1772–8; *Allgemeine Theorie des Denkens und Empfindens*, &c., Berlin, 1776, 8vo,—this essay obtained the prize assigned by the Royal Society of Berlin for that year; *Von dem Begriff der Philosophie und ihren Theilen*, Berlin, 1778, 8vo,—a short essay, in which he announced the plan of his lectures on being appointed to the professorship at Halle; *Lobschrift auf Herrn Johann Thunmann, Prof. der Weltweisheit und Beredsamkeit auf der Universität zu Halle*, Halle, 1779, 8vo; *Amyntor, eine Geschichte in Briefen*, Berlin, 1782, 8vo. This work was written with the view of counteracting the influence of those sceptical and Epicurean principles in religion and morals which were then so prevalent in France, and thence rapidly spreading amongst the higher ranks in Germany. It is composed with great elegance and perspicuity, and exhibits much philosophical reflection, and knowledge of the world. The story is simple, and seems to have been merely intended as a vehicle for the sentiments. *Ueber die Zeichen der Aufklärung einer nation*, &c., Halle, 1783, 8vo; *Theorie der Schönen Kunste und Wissenschaften*, &c., Halle, 1783, 8vo, 3d ed. 1790; *Vermischte Schriften*, Halle, 1784; *Neue Vermischte Schriften*, Ib. 1786; *Allgemeine Geschichte der Philosophie*, &c., Halle, 1788, 8vo; 2d ed. with a continuation and chronological tables, 1796. Eberhard published also an abridgment of this work in 1794. *Versuch einer Allgemeinen-Deutschen Synonymik*, &c., Halle and Leipsic, 1795–1802, 6 vols. 8vo. This is esteemed a classical work on the synonymes of the German language. An abridgment of it was published by the author in one large volume 8vo, Halle, 1802. *Handbuch der Aesthetik*, &c., Halle, 1803–1805, 4 vols. 8vo. Besides the works above mentioned, Eberhard contributed a number of small tracts and essays to various periodical and scientific publications, and translated several foreign works. He was also the editor of the *Philosophical Magazine*, Halle, 1788–1792, and of the *Philosophical Archives*, Halle, 1793–1795. These two periodical works, which are now little read, were instituted for the purpose of controverting the metaphysical principles of Kant, and of vindicating the doctrines of Leibnitz and Wolf. Frederick Nicolai published a Memoir on the life and character of Eberhard, Berlin and Stettin, 1810, 8vo. See also K. H. Jördens, *Lexicon Deutscher Dichter und Prosaisten;* and *Biographie Universelle.* (J. C.)

EBINGEN, a town of Würtemberg, circle of Balingen on the Schmieha, with 4400 inhabitants, engaged chiefly in the manufacture of woollen cloths, hosiery, hats, and leather.

EBIONITES, a Jewish-Christian sect of the first century, who separated themselves from that branch of the Nazarenes that remained faithful to the apostolic doctrine. They differed from the Nazarenes in this, that they asserted the permanent obligation of the whole Mosaic law, and on this account they retained circumcision, and highly valued the Pentateuch. They regarded Christ as a mere man; and used a translation of the Gospel of Matthew in Greek characters, but in the Syro-Chaldaic dialect. At a later period they adopted other books attributed to St James, St Peter, and Clement. Epiphanius and Tertullian both derive the name from Ebion, a disciple of Cerinthus, who is said to have founded the sect. Others derive it from the Hebrew *Ebionim, i.e.* poor people, a name at first either given to the Christians by the Jews, or probably assumed by the former on account of their poverty. They originally planted themselves at Pella, on the other side of Jordan, and gradually spread from thence into the Decapolis, Peræa, and Syria. They were afterwards merged with the Elcesaites. The ancient authorities on the subject of the Ebionites are Origen, Epiphanius, and Eusebius. See also the dissertations of Mosheim, Credner, Detmer, and Walch.

EBONY (ἔβενος), a species of wood, brought principally from the East. It is exceedingly hard and heavy, of great durability, and susceptible of a very fine polish; and hence it is wrought into a variety of toys, and used in mosaic and other kinds of inlaid work. As a dye also it yields a fine green tincture. There are several varieties of ebony, namely, black, red, green, and yellow; but the black is the most valuable. Ebony is obtained from several species of *Dios-*

pyros ebenus, a tree of the natural order *Ebenaceæ*. The supply of this valuable wood comes principally from Madagascar, the Mauritius, and Ceylon. The heart of the tree yields the finest ebony. The best is jet black, free from veins and rind, of a very dense structure, astringent, and of an acrid pungent taste. When laid on burning coals it yields an agreeable perfume; and when green it readily takes fire from its abundance of oil. See BOTANY, Nat. Ord. 135.

The facilities for staining pear-tree and other hard woods of a fine black colour has greatly limited the use of genuine ebony in modern times. It is stated in M'Culloch's *Commercial Dictionary* that the price of ebony varies in the London market from L.5 to L.20 a ton, and that the quantities imported are but inconsiderable.

EBORACUM, or as it is sometimes written EBURACUM, the ancient name of York, which in the days of the Roman empire in Britain was a place of considerable importance. It was at Eboracum that the Emperors Constantius and Severus died, and that Constantine the Great was born. Numerous remains of the Roman occupation have been found at York, throwing much light upon the social customs and domestic manners of that people. See YORK.

EBRO, a river of Spain. See SPAIN.

EBUDÆ, or HEBUDES, the ancient name of the Hebrides or Western Isles.

EBULLITION, the motion produced in any liquid by the escape of a portion of it converted into an aeriform state by heat; as exemplified in the boiling of water, the slaking of lime, &c.

ECASTOR, or MECASTOR, an oath in which Castor was invoked. It was not the custom for men to swear by Castor, nor for women by Pollux.

ECATÆA, Ἑκάταια, in *Grecian Antiquity*, statues erected to the goddess Hecate, as the giver of riches and prosperity, and the protectress of new-born babes.

ECBATANA, now ACHMETHA, a city in Media. The derivation of the name is doubtful; but Major Rawlinson (*Geogr. Journal*, x. 134) has left little question that the title was applied exclusively to cities having a fortress for the protection of the royal treasures. In Ezra we learn that in the reign of Darius Hystaspes the Jews petitioned that search might be made in the king's treasure-house at Babylon for the decree which Cyrus had made in favour of the Jews (Ezra, v. 17). Search was accordingly made in the record-office ("house of the rolls"), where the treasures were kept at Babylon (vi. 1): but it appears not to have been found there, as it was eventually discovered "at Achmetha, in the palace of the province of the Medes" (vi. 2). It is here worthy of remark, that the LXX. regarded "Achmetha," in which they could hardly avoid recognising the familiar title of Ecbatana, as the generic name for a city, and accordingly rendered it by πόλις; and that Josephus, as well as all the Christian Greeks, while retaining the proper name of Ecbatana, yet agree, with the Greek Scriptures, in employing the word βάρις to express the Hebrew *Birtha* ("the palace"), which is used as the distinctive epithet of the city.

In Judith i. 2-4, there is a brief account of Ecbatana, in which we are told that it was built by Arphaxad, king of the Medes, who made it his capital. It was built of hewn stones, and surrounded by a high and thick wall, furnished with wide gates and strong and lofty towers. Herodotus ascribes its foundation to Deioces, in obedience to whose commands the Medes erected "that great and strong city, now known under the name of Agbatana, where the walls are built circle within circle, and are so constructed that each inner circle overtops its outer neighbour by the height of the battlements alone. This was effected partly by the nature of the ground (a conical hill), and partly by the building itself. The number of the circles was seven, and within the innermost was the palace of the treasury. The battlements of the first circle were white, of the second black, of the third scarlet, of the fourth blue, of the fifth orange; all these were brilliantly coloured with different pigments; but the battlements of the sixth circle were overlaid with silver, and of the seventh with gold. Such were the palace and the surrounding fortification that Deioces constructed for himself; but he ordered the mass of the Median nation to construct their houses in a circle around the outer wall." (Herodot. i. 98). It is contended by Major Rawlinson (*Geogr. Journal*, x. 127) that this story of the seven walls is a fable of Sabæan origin, the seven colours mentioned being precisely those employed by the Orientals to denote the seven great heavenly bodies, or the seven climates in which they revolve. He adds (p. 128), "I cannot believe that at Agbatana the walls were really painted of these colours: indeed, battlements with gold and silver are manifestly fabulous; nor do I think that there ever could have been even seven concentric circles; but in that early age, where it is doubtful whether mithraicism or fire-worship had originated in this part of Asia, it is not at all improbable that, according to the Sabæan superstitions, the city should have been dedicated to the seven heavenly bodies, and perhaps a particular part assigned to the protection of each, with some coloured device emblematic of the tutelar divinity."

This Ecbatana has been usually identified with the present Hamadan. Major Rawlinson, however, while admitting that Hamadan occupies the site of the Median Ecbatana, has a learned and most elaborate paper in the *Geographical Journal* (x. 65-158; *On the Site of the Atropatenian Ecbatana*), in which he endeavours to show that the present Takht-i-Suleiman was the site of another, the Atropatenian Ecbatana; and that to it, rather than to the proper Median Ecbatana, the statement in Herodotus and most of the other ancient accounts are to be understood to refer. The major, indeed, seems inclined to consider the Ecbatana of the apocryphal books as his Atropatenian Ecbatana; but is rather more doubtful in claiming it as the Achmetha of Ezra. But without undertaking to determine what amount of ancient history should be referred to the one or to the other, we feel bound to conclude that Hamadan was the site of the Achmetha of Ezra, and the Ecbatana of the Apocrypha: 1. Because it is admitted that the Median Ecbatana was a more ancient and more anciently great city than the Atropatenian metropolis; 2. Because the name "Achmetha" may easily, through the Syrian Ahmethan, and the Armenian Ahmetan, be traced in the Persian Hamadan; 3. And because all the traditions of the Jews refer to Hamadan as the site of the Achmetha and Ecbatana of their Scriptures.

Hamadan is still an important town, and the seat of one of the governments into which the Persian kingdom is divided. It is situated in N. Lat. 34. 53., E. Long. 40., at the extremity of a rich and fertile plain, on a gradual ascent, at the base of the Elwund Mountains, whose higher summits are covered with perpetual snow. Some remnants of ruined walls of great thickness, and also of towers of sun-dried bricks, present the only positive evidence of a more ancient city than the present on the same spot. Heaps of comparatively recent ruins, and a wall fallen to decay, attest that Hamadan has declined from even its modern importance. The population is said by Southgate to be about 30,000, which probably exceeds the truth very considerably. It is little distinguished, inside, from other Persian towns of the same rank, save by its excellent and well-supplied bazaars, and the unusually large number of khans of rather a superior description. This is the result of the extensive transit trade of which it is the seat, it being the great centre where the routes of traffic between Persia, Mesopotamia, and Persia, converge and meet. Its own manufactures are chiefly in leather. Many Jews reside here, claiming to be descended from those of the Captivity who

remained in Media. Benjamin of Tudela says that in his time the number was 50,000. Modern travellers assign them 500 houses; but the Rabbi David de Beth Hillel (*Travels*, pp. 85-87, Madras, 1832), who was not likely to understate the fact, and had the best means of information, gives them but 200 families. He says they are mostly in good circumstances, have fine houses and gardens, and are chiefly traders and goldsmiths. They speak the broken Turkish of the country, and have two synagogues. *They* derive the name of the town from "*Haman*" and "*Mede*," and say that it was given to that foe of Mordecai by King Ahasuerus. In the midst of the city is a tomb which is in their charge, and which is said to be that of Mordecai and Esther. It is a plain structure of brick, consisting of a small cylindrical tower and a dome (the whole about 20 feet high), with small projections or wings on three sides. Within are two apartments—a small porch formed by one of the wings, and beyond it the tomb-chamber, which is a plain room paved with glazed tiles. In the midst, over the spots where the dead are supposed to lie, are two large wooden frames or chests, shaped like sarcophagi, with inscriptions in Hebrew and flowers carved upon them. There is another inscription on the wall, in bas-relief, which, as translated by Sir Gore Ousley, describes the present tomb as having been built over the graves of Mordecai and Esther by two devout Jews of Kashan, in A.M. 4474. The original structure is said to have been destroyed when Hamadan was sacked by Timour. As Ecbatana was then the summer residence of the Persian court, it is probable enough that Mordecai and Esther died and were buried there; and traditional testimony, taken in connection with this fact, and with such a monument in a place where Jews have been permanently resident, is better evidence than is usually obtained for the allocation of ancient sepulchres. The tomb is in charge of the Jews, and is one of their places of pilgrimage. Kinneir, Ker Porter, Morier, Frazer, and Southgate, furnish the best accounts of modern Hamadan. (See PERSIA.)

History mentions another Ecbatana, in Palestine, at the foot of Mount Carmel, towards Ptolemais, where Cambyses died (Herod. iii. 64; Plin. v. 19). It is not mentioned by this or any similar name in the Hebrew writings: and we are at a loss to discover the grounds which Major Rawlinson says exist for concluding that there was a treasury in this position (*Geogr. Journ.* x. 134).

ECCENTRIC, deviating or departing from the centre. In geometry the term is applied to circles and spheres which have different centres, and consequently are not parallel; as opposed to *concentric*, or such as have a common centre. In astronomy it denotes the distance of the centre of a planet's orbit from the centre of the sun—or the distance between the centre of an ellipse and its focus. In mechanics the term is applied to any revolving motion of which the axis is not placed in the centre.

ECCHELLENSIS, ABRAHAM, a learned Maronite, associated with Le Jai in the preparation of his Polyglott Bible. He was at first the coadjutor of Gabriel Sionita, a countryman of his, who afterwards quarrelled with him, and brought his case before parliament. In 1636 the congregation *de Propaganda Fide* associated him with those whom they had employed in making an Arabic translation of the Scriptures; and he removed to Rome for that purpose in 1652. While professor of oriental languages at Rome, he translated into Latin the fifth, sixth, and seventh books of Apollonius's Conics; a task in which he was assisted by John Alphonso Borelli. Ecchellensis died at Rome in 1664.

ECCLES, a manufacturing parish of Lancashire, England, 4 miles from Manchester. Pop. (1851) 41,497, chiefly engaged in the several branches of the cotton manufacture.

ECCLESALL-BIERLOW, a village in the west riding of Yorkshire, parish of Sheffield, $3\frac{1}{2}$ miles from the town of that name. The inhabitants, like those of Sheffield, are engaged chiefly in the manufacture of iron and steel articles. Pop. of township, which includes 26 hamlets, (1851) 24,552.

ECCLESHALL, a market-town of England, in the county of Stafford, on the river Sow, $6\frac{1}{2}$ miles W.N.W. of the town of Stafford. It is a neatly built place, and contains a castle, the residence of the bishop of Lichfield. In its church Bishop Halse concealed Queen Margaret when she fled from Muckleston. Market-day Friday. Pop. of parish (1851) 4696.

ECCLESIA, in *Grecian Antiquity*, the general assembly of Athenian citizens, who met from time to time to discuss public affairs. Ecclesiæ were of two kinds, ordinary and extraordinary. The first of these were held three times every month; while the others were only summoned on some pressing emergency. When any measure of unusual importance was to be publicly debated, the people were summoned from the country by special messengers. An assembly thus convened was called a *cataclesia*.

Much discussion has taken place as to the exact days of the month on which the ecclesiæ were held; but the result has only been to prove either that there were no days invariably fixed for them, or that we have no data by which to determine accurately what these days were. In Ulpian it is stated that when there were three assemblies a-month, the first fell on the eleventh, the second on the twentieth, and the third about the thirtieth of the month.

Ecclesiæ were originally held in the Agora or Forum. The place of meeting was subsequently removed to the Pnyx, and afterwards to such of the greater temples as might be most convenient. The Pnyx lay to the west of the Areopagus, and commanded an extensive view. It was partly within the city walls, and had an area of about 12,000 square yards. On its northern side, cut out of the solid rock, was the *bema* or hustings from which the speakers addressed the people. From this tribunal a splendid view of the principal buildings of the city might be had. The right of assembling the people lay with the presidents of the senate or Council of Five Hundred, who both advertised beforehand the business to be discussed, and on the day of meeting sent round a crier to remind the citizens that their presence was required. In times of war, however, or other national crises, the generals of the army sometimes assumed this privilege, though it was necessary for them in doing so to give notice of their intention by a public proclamation. They also sometimes claimed the right of preventing the ecclesia from assembling; but their claims to this privilege were not generally recognised. Such of the citizens as refused to attend were fined, and six magistrates called Lexiarchs were appointed to collect the fines. To assure a full meeting, the custom was ultimately introduced of paying the poorer classes a small sum for their attendance. This sum was originally an obolus, but after the time of Pericles it was raised to three.

ECCLESIA is also the name in Hellenistic Greek for the Christian Church.

ECCLESIASTES, or the PREACHER, one of the canonical books of the Old Testament. The Hebrew word *Coheleth*, of which the above two titles are a translation, is of somewhat difficult etymology; but if the merely modern shade of meaning attached to the word *preacher* be avoided, there is no reason to abandon this its ancient title for the fanciful renderings, *collector*, *assembly*, *academy*, &c., which have been popular abroad.

The history of the interpretation of Ecclesiastes presents the same great features with that of the other books of Scripture. Of its admission into the canon there is not even the shadow of a doubt; although some of the learned Jews mentioned in the Talmud seem to have been haunted with scruples in regard to its heresy, its "contradictions," and

its "materialism." From these Talmudists to Theodore of Mopsuestia, and from that period again till the Reformation, its orthodoxy remained generally unchallenged both in the synagogue and in the church. During the last and the present century it has shared the fate of all ancient documents at the hands of Continental Rationalism, and is now emerging from this its fiercest and apparently final ordeal.

The points under dispute are, severally, its unity and plan, its ethical characteristics, its date and authorship. Its unity is denied by the whole Wolfian school of critics; but their schemes of partition into dialogues and disjointed narratives, rival poems, literary discussions, ethical aphorisms, and unfinished practical essays, are more than mutually destructive. The peculiarity of the diction, and the unity of the subject, is too marked to admit of the possibility of divided authorship. In regard to the plan of the book, their rival theories are equally at fault. Between the scheme of Kaiser, who detects throughout historical and prophetic delineations of the characters and reign of the later kings, and that of Ewald and Hitzig, who recognise in it the utterances of incarnate wisdom, it may easily be imagined that there are intermediate hypotheses interminable. The most plausible ground for recognising a plurality of authors, and consequently a frequent divergence of plan in the book, lies in the abruptness of its transitions, which are in fact made without regard to logical accuracy or rigorous simplicity of method; but this can hardly be recognised as necessarily inconsistent either with a fixed plan or with a unity of authorship, since, as is the case with the Song of Solomon, it enters into the very conception of the book, that it should present its main theme abruptly from a variety of opposite points of view. The theme itself, which is the vanity of all earthly things, is never lost sight of; and however far the orbit of its illustration sweeps, there is ever a periodical return to this dreary central thought. So entirely, however, does the ethical value which we attach to it depend on the hypothesis which we hold in regard to its structure, that De Wette on one theory rejects the book entirely as unhinging the doctrine of final retribution, and Moses Stuart on another receives it as containing more explicit reference to this grand event than any other book of the Old Testament. If, as some have supposed, it be a mental autobiography of Solomon, in which he brings to light the Epicurean maxims that soothed and incited him in his career of folly and dissipation, the ethical difficulties vanish.

The date of Ecclesiastes is not so precisely determined by its diction as was at one time confidently supposed. Its alleged Hellenisms, at one time triumphantly paraded as the demonstration of its late origin, have been entirely eliminated by later scholars; and the rash assertion that it is coloured with the peculiar Greek philosophizing in regard to the chief good, has been successfully disproved. Its Chaldaisms, which have at least as great affinity to patriarchal as to modern Hebrew, have been reduced to some eight or ten instances. And taking into account the necessities, or even the eccentricities of philosophical language, it is not too much to say that these might have been written in the golden age of Hebrew literature. The political sketches in the book have also been employed with a view to ascertain its date. Setting out on the principle that the author is depicting the miseries of contemporary history, almost all the leading epochs of later Jewish history have been adduced as answering the description. The absence, however, of certain well-known features, such as the prevalence of idolatry, is fatal to such a theory; and it is somewhat remarkable that later writers have been compelled to abandon all except the *terra incognita* of Jewish history, and to regard the description as alone applicable to the time when the Holy Land was a mere Persian province. The researches of Kaiser, above alluded to, at least show that the delineations do not refer to any well-defined period. They are in truth only vivid sketches of phenomena that are ceaselessly repeated in Eastern political history.

The authorship of Ecclesiastes, if not attributed to Solomon, must remain for ever a matter of uncertainty. All other names rest merely on conjecture. To those who regard Solomon's name as introduced merely as the representative of wisdom, it must on the one hand be conceded that such a practice was common with writers who flourished after the exile; but on the other hand it seems equally clear, that as the whole scope of the book points naturally to the real authorship of Solomon, the book of Ecclesiastes, if this authorship be disproved, must be ranked as at the best a pious forgery, and must be condemned to take its place with other apocryphal productions. Much, however, yet remains to be done in investigating the minutiæ of this question. The affinities of Ecclesiastes in thought and style with the book of Proverbs are certainly as marked as the discrepancies of the two books in diction. The proverbial style in both is the same; and even the varieties of the diction, although they may seem to indicate that they are the production of different authors, cannot be adduced as proving that they were written at widely different epochs. The sketches are undoubtedly such as might have been anticipated from a king, who, in his own history and in his relation to foreign despotisms, had brought everything that was false in morality and false in politics within the circle of his own experience; and it seems strange that the incongruity of the sentiments should not have been detected by those who knew the social condition of the people in Solomon's reign far better than we can ever hope to do. The expression (i. 12), "I the preacher *was* king," does not decide the question of the authorship; it has evident reference to the *testamentary* character of the treatise, which, as the last of Solomon's productions, we might beforehand expect to be written in a dialect somewhat marked with foreign idioms. Twenty years of habitual intercourse with the representatives of foreign nations, whose languages, though distinct, had yet a very close resemblance to Hebrew, must have sensibly affected the dialect of the court; and to us it seems not unsuitable that the penitential acknowledgments of Solomon should be handed down to posterity in the broken dialect which was the very symbol of his self-degradation. (R. W—N.)

ECCLESIASTICAL (ἐκκλησία, *an assembly or meeting*), pertaining or relating to the church; as ecclesiastical polity, jurisdiction, history, &c.

ECCLESIASTICUS, or the Wisdom of Jesus, son of Sirach, one of the apocryphal books of the Old Testament. It consists of an anthology of proverbs drawn from other compilations of same kind, and also from the experience of the writer, who lived about 210–180 B C. Its Hebrew original is now lost. It is called Ecclesiasticus because put into the hands of the catechumens in the early church.

ECCOPROTICS (ἐκ and κόπρος, *fæces*), in *Medicine*, laxative remedies which purge gently; mild cathartics.

ECDICI, Ἔκδικοι, among the ancients, patrons of cities, who defended their rights, and took care of the public money. Their office resembled that of the modern syndics.

ECHELON (Fr. *échelle, a ladder*), in military tactics, the position of an army when its divisions are arranged one behind the other, in the form of steps.

ECHINADES, a group of islands at the mouth of the Achelous, off the coast of Acarnania. In the days of Herodotus some of these islands had become incorporated with the mainland, in consequence of the great quantities of alluvial soil annually brought down by the Achelous. Thucydides expected that in course of time the entire group would in this manner become part of the continent; but his anticipations have not even yet become realized. The alluvial deposits had ceased to a great extent in the time of Pausanias, who attributed this circumstance to the fact

that the lands of Ætolia were no longer cultivated so well as they once had been. Notice is taken of the Echinades by Homer, who mentions that Meges, the son of Phyleus, joined the Grecian expedition against Troy with 40 ships. Dulichium is specified as the particular island over which this Phyleus reigned, and its fertility is highly praised by the poet. It is not exactly known what this Dulichium really was. Some ancient writers identified it with Cephalonia; Strabo maintains that it was the same with *Dolicha*, one of the Echinades. None of these islands, however, as they now exist, bear out the Homeric description of Dulichium. Col. Leake observes that Petala, the largest of the group, seems to have the best claim to that distinction. Pliny gives a catalogue of nine of these islands: the group as it now stands comprises between twenty and thirty islands, some of which, however, are little more than barren reefs. Nine only of the whole number are at present under cultivation.

ECHINATE or ECHINATED (Lat. *echinus, a hedgehog*), set with prickles or spines; prickly like a hedgehog; a term of frequent use in natural history.

ECHINITE, a name of the fossil sea-urchin, frequently found in chalk pits.

ECHINODERMATA, the first class of Cuvier's fourth great division of the animal kingdom, commonly called Zoophytes, or radiated animals. It includes, among numerous other species, the star-fish, sea-urchins, &c. See ZOOPHYTES, and ANIMAL KINGDOM.

ECHINUS, the general name of the sea-urchins. See ZOOPHYTES.

ECHINUS, in *Architecture*, a kind of egg-shaped moulding. See Glossary to ARCHITECTURE.

ECHO, a mountain-nymph, employed by Jupiter to baffle and mislead Juno, while he himself sported with her sister Oreades among the glades of Bœotia. As soon as Juno discovered the deception, she punished the nymph by changing her into an echo. In this condition she became enamoured of Narcissus; and when that youth failed to return her love, she pined away, till at length nothing remained of her but her voice.

ECHO, from ἦχος *a sound*, or rather from ἠχώ *an echo*. Sounds are reflected from the surfaces of hard bodies, such as hills, rocks, walls, &c., in such a manner that the angle of reflection is equal to the angle of incidence; and, in certain circumstances, these reflexions produce very remarkable echoes. The form of the reflecting surface, plane, or convex, or concave, &c., modifies the reflection. Sounds are also reflected by the surface of water, and sometimes even by clouds. In an elliptical room, if the sound proceed from one of the foci of the ellipsis, a person placed in the opposite focus will hear the sound much more distinctly than if placed in any other part of the room. The phenomena of whispering domes and whispering galleries depend on similar principles,—for example, in the case of the dome of St Paul's Cathedral, London. Some echoes repeat only sounds of a certain pitch. Others are said to repeat sounds, but not at the same pitch as the original sounds. Such is the echo at Roseneath in Scotland, which is said to repeat a musical sound three times, but each time lower and lower by the interval of a tone. There seems to be some error in this observation at Roseneath. An echo at Genetay, six miles from Rouen, is said to repeat words several times in varied tones. Other echoes, called *polysyllabical*, repeat many syllables or words. *Multiple* or *tautological* echoes repeat the same word several times; as at the castle of Simonetta, about two miles from Milan, where the echo repeats a word about twenty times over. Another, near Coblentz, is said to repeat a word seventeen times. Gassendi mentions an echo near the tomb of Cecilia Metella at Rome, which repeated the first verse of the Æneid eight times. Dr Plot, in his Natural History of Oxfordshire, mentions a remarkable echo at Woodstock Park, near Oxford, which repeats seventeen syllables in the day time, and twenty at night. Another echo, on the north side of Shipley Church, in Sussex, is said by Harris (*Lex. Tech.*) to repeat distinctly, in favourable circumstances, twenty-one syllables.

ECHO is also used for the place where the repetition of the sound is produced or heard. In echoes, the place where the speaker stands is called the *phonic centre*, and the object or place that returns the voice the *phonocamptic centre*.

ECHO, in *Music*, is a term applied to that sort of airs or pieces in which certain passages are repeated with diminished intensity of sound. Paisiello, in his *Proserpina*, and Mayer, in his *Elisa*, employed this kind of echo. Skilful performers on the horn, the flute, the clarinet, &c., produce echo passages with great effect. A certain organ stop is also called an echo; and on the same instrument an echo is imitated by means of alternate loud and soft stops,—the latter repeating phrases given out by the former. (G. F. G.)

ECHO, in *Architecture*, a term applied to a certain kind of vault or arch, made commonly of an elliptic or parabolic figure, for the purpose of producing artificial echoes.

ECIJA, an ancient city of Spain, province of Seville, on the Xenil (a tributary of the Guadalquiver), which is here crossed by a fine old bridge, 53 miles E.N.E. of Seville. Pop. 23,722. It was a considerable city in the time of the Romans, by whom it was called *Astigo;* and, according to Pliny and Pomponius Mela, was the rival of Cordova and Seville. Many inscriptions and interesting relics of antiquity are to be found in the town and its vicinity. It is surrounded by old walls, and the streets are narrow and crooked: but it has a noble square in its centre adorned with a fine fountain. There are six churches, several of them richly adorned, and many hospitals and monasteries. From the extreme heat of this town, it has acquired the sobriquet of *la Sartenilla* or the frying-pan. Outside the town near the river is a fine *alameda* or public promenade, planted with trees, and adorned with statues and fountains. Ecija has manufactures of coarse cloths, linen, and leather; and the vicinity is fertile in corn and wine.

ECKERNFORDE, a seaport-town of Denmark, duchy of and 15 miles E.S.E. of Schleswig. It is situated on an inlet of the Baltic, and has a good harbour and a considerable trade. Pop. 4058.

ECKIUS or ECHIUS, JOANNES (1483–1543), the antagonist of Luther, was born in Suabia. His family name was Mayer. He was professor at Ingolstadt, and at the Reformation disputed both with Luther and Carlstadt. At the diet of Augsburg he argued against the Protestant Confession. He wrote a work entitled *Enchiridion Controversiarum; Apologia contra Bucerum;* a tract on the Mass; an Exposition of Haggai; and several smaller works.

ECKMUHL or EGGMUHL, a small village of Bavaria, on the Great Laber, 15 miles S.S.E. of Regensburg, celebrated for the important victory gained here by the French over the Austrians on 22d April 1809, and which obtained for Davoust the title of prince of Eckmühl.

ECLECTICS (*Electici*), a name given to some ancient philosophers, who, without attaching themselves to any particular sect, took whatever they judged good and solid from each; and hence their denomination, from ἐκ and λέγειν to choose. Laertius observes that they were also, for the same reason, denominated *analogetici;* but that they call themselves *philalethes*, or lovers of truth. The chief or founder of the eclectics was Potamon of Alexandria, who lived under Augustus and Tiberius, and who, weary of doubting of all things with the Sceptics and Pyrrhonists, formed the Eclectic sect, called by Vossius the Eclective.

Towards the close of the second century, a sect arose in the Christian Church under the denomination of Eclectics,

or modern Platonists, professing to make truth the only object of their inquiry, and to be ready to adopt from all the different systems and sects such tenets as they thought agreeable to it. However, they preferred Plato to the other philosophers, and looked upon his opinions concerning God, the human soul, and things invisible, as conformable to the spirit and genius of the Christian doctrine. One of the principal patrons of this system was Ammonius Saccas, who laid the foundation of that sect afterwards distinguished by the name of the New Platonists in the Alexandrian school.

There was also a certain ancient sect of physicians called Eclectics, of whom Archigenes, who lived under Trajan, was the chief, and selected from the opinions of all the other sects those which he considered best and most rational. Hence they are called *eclectics*, and their prescriptions *medicina eclectica*.

ECLIPSE (ἔκλειψις, from ἐκλείπειν *to forsake, to fail*), in *Astronomy*, an obscuration of the light of the sun, moon, or other heavenly body, by the interposition of another heavenly body between us and that body. See ASTRONOMY.

ECLIPTIC, in *Astronomy*, a great circle of the sphere, supposed to be drawn through the middle of the zodiac, making an angle with the equinoctial of about 23° 30′ which is the sun's greatest declination; or, more strictly speaking, it is that path or way among the fixed stars which the earth appears to describe to an eye placed in the sun. The angle of inclination of the equator and ecliptic is called the obliquity of the ecliptic. This has been subject to a small irregular diminution since the time of the earliest observations on record. Its mean diminution per century is about 48″. See ASTRONOMY.

ECLIPTIC, in *Geography*, a great circle on the terrestrial globe, answering to, and falling within, the plane of the celestial ecliptic. See GEOGRAPHY.

ECLOGUE, in *Poetry*, a kind of pastoral composition, in which shepherds are introduced conversing together. The word is formed from the Greek ἐκλογή *choice;* so that, according to the etymology, eclogue should be a select piece; but custom has assigned to it a further signification, namely, a little elegant composition in a simple natural style and manner.

The idyl and the eclogue, in their primary sense, are the same; but custom has appropriated the name of *eclogue* to pieces in which shepherds are introduced; and *idyl* to those written in a simple style, but without any pastoral interlocutors.

ECLUSE. See CLUSIUS.

ECONOMISTS.

IT is not generally known how much the science of politics, that master science, the late offspring of the improved reason of modern times, is indebted to the philosophers who are known to the world by the title of economists. They were, it is true, preceded in this country by Hobbes and by Locke, and in France by Montesquieu; but in analysing the frame of civil society, they added considerable lights to those which had been communicated by their predecessors; and they attempted to point out the mode of combining the various springs of social action in a more liberal and beneficent system than had yet been recommended to the world.

It is worthy of remark, that the merits of this sect, in the secondary department of *political economy*, have so much obscured their important speculations on the great questions respecting the best possible order capable of being given to society, that they are, in this country at least, wholly unknown, except in the character of political economists; though their political economy formed only a small and subordinate branch of their entire system; and, what is indeed extraordinary, we know not a book in the English language in which an account of that system is to be found.

This article is intended to contain, 1*st*, the history of the sect; 2*dly*, an account of their system; and, 3*dly*, some observations, pointing out the principal errors into which they have fallen.

I. M. de Gournay appears to have been the first man in France who had formed any systematic notions on the real principles of trade. It is true, indeed, that Fenelon had recommended, on the direct suggestion of good sense, detached from theory, the practice of freedom of trade. The Marquis d'Argenson was celebrated for the sound and important maxim, *Pas trop gouverner;* and the memorable advice of the merchants to the meddling Colbert was well known, *Laissez-nous faire.* Another of the more peculiar doctrines of the economists was expressed in the famous maxim of the great Duc de Sully, *Que le labourage et le pâturage sont les mammelles de l'état;* and Montesquieu had brightly but superficially run over several of the questions relative to trade.

For such lights as M. de Gournay did not derive from his own reflections, he seems to have been chiefly indebted to the writers of England; but there appears some reason to conclude that the best of these had not fallen in his way. We do not perceive, for example, any sign of acquaintance with the writings of Locke.

Jean-Claude-Maria Vincent, Seigneur de Gournay, was an extraordinary man for the age and country in which he was produced. He was born at St Malo, in the month of May 1712, the son of Claude Vincent, one of the most considerable merchants of the place. Destined to commerce by his parents, he was sent to Cadiz when scarcely seventeen years of age. His vigilant attention to business did not hinder him from finding time, well husbanded and diligently applied, not only for storing his mind with general knowledge, but for unravelling the combinations of commerce, and ascertaining its elementary principles. After he had raised himself to great eminence as a merchant, and to a high reputation for knowledge of the principles of commerce, the ministers of France conceived the design of turning his knowledge to advantage in the office of intendant of commerce, as they call it, to which he was raised in 1751.

No sooner was M. de Gournay invested with his office, than he began to wage war with the established system of regulations and restrictions, which the experience of twenty years of mercantile practice the most varied and the most extensive, discussions with the most intelligent merchants of Holland and of England, the perusal of the best writers on the subject, and the impartial application of his own philosophical thoughts, had all conspired to make him regard as a source, not of national advantage, but of continual vexation and hardship to individuals, and of poverty to the state. "He was astonished," says M. Turgot, "to find that a citizen could neither make nor sell a commodity, without having purchased a privilege, by getting himself made, at a great expense, a member of some corporation; that if he made a piece of cloth, for example, of any quantity and quality different from those commanded in certain regulations, instead of being allowed to sell it to those purchasers whom such quantity and quality suited the best, he should be condemned to see it cut in pieces, and to pay a fine heavy enough to reduce a whole family to beggary. He could not conceive

how, in a country where the succession to titles, to estates, and even to the crown itself, rested upon custom, and where the application of even the punishment of death was rarely guided by any written definitions, the government should have thought proper to fix by written laws the length and breadth of each piece of cloth, and the number of threads which it ought to contain. He was not less astonished to see the government take in hand to regulate the supply of commodities; proscribe one sort of industry in order to make another flourish; shackle with peculiar restrictions the sale of the most necessary articles of subsistence; prohibit the storing of commodities, of which the quantity produced varies greatly from year to year, while the quantity required for consumption is pretty nearly the same; restrain the export and import of a commodity subject to the greatest fluctuation of price; and dream of insuring the plentiful supply of corn by rendering the condition of the labourer more uncertain and more wretched than that of any other part of the community." (*Œuvres* de M. Turgot, iii. 333.)

It may easily be imagined that M. de Gournay would find himself encountered by opposition the moment he endeavoured to introduce his beneficial views into practice. The grand instruments of this opposition were certain words and phrases, which have been used to screen misrule in every country in which the voice of reform has begun to be raised. "M. de Gournay," says Turgot, "was opposed, under the names of an 'innovator' and a 'theorist,' for endeavouring to develop the principles which experience had taught him, and which he found universally recognised by the most enlightened merchants of every part of the world among whom he had lived. The principles marked out for reprobation, under the title of the 'new system,' appeared to him to be exactly the principles of plain good sense. The whole of this system was founded upon the certain maxim, that, in general, each man is a better judge of his own interest, than another man to whom it is a matter of indifference. From this M. de Gournay concluded, that, when the interest of individuals is precisely the same with the general interest, the best thing to be done is, to leave every man at liberty to do what he likes. Now he held it as impossible, that in commerce, fairly left to itself, the interest of the individual should not coincide with the interest of the community." The proof which M. Turgot gives of the fundamental proposition, that the interest of the individual and of the community in a free commerce are the same, we need not repeat; because it can neither be rendered more clear nor more cogent than it is already in works with which every person is familiar, who is at all conversant with political science.

"From this principle M. de Gournay concluded, that the sole duties of government with regard to commerce are: 1. To render to all the branches of industry that precious liberty, of which the prejudices of barbarous times, the proneness of governments to lend themselves to the gratification of individual interests, and the pursuit of a mistaken good, have conspired to deprive them: 2. To facilitate the exercise of industry and ingenuity to every member of the community, exciting thereby the greatest competition among sellers, and ensuring the greatest perfection and cheapness of the commodities sold: 3. To admit the greatest competition among buyers, by opening to the seller every possible market; the sole means of encouraging reproduction, which hence derives its only reward: 4. To remove every obstacle by which the progress of industry is retarded, by depriving it of its natural reward."

It is to M. de Gournay, therefore, that Turgot ascribes the origin of political economy in France. "It is to the ardour," says he, "with which M. de Gournay endeavoured to direct to the study of commerce and of political economy, all the talent which he was able to discover, and to the facility with which he communicated the lights which he himself had acquired, that we ought to ascribe the happy fermentation which for some years has been excited on these important subjects; a fermentation which arose two or three years after M. de Gournay was intendant of commerce, and has since that time procured us several works calculated to wipe off from our nation that reproach of frivolity, which, by its indifference for the more useful studies, it had but too justly incurred."

Francis Quesnay was born in the village of Ecqueville in the year 1694. According to M. Dupont de Nemours, the editor and commentator of the works of Turgot, and a zealous economist, he was the son of a small proprietor, who cultivated his own little property; and he was eminently indebted to his mother for the forming of his mind. Though he was educated as a physician, and rose to such eminence in his profession as to be first physician to the king, the early occupation of his mind on the business of agriculture had given the current of his thoughts a permanent direction; and when he was summoned to reflect on the sources of wealth, by the discussions probably to which the speculations of M. de Gournay had given birth, agriculture was the object on which his attention was more particularly fixed. He produced several works on different points of the science and practice of medicine; and it was only at a late period of life that his works on political economy appeared. His chief production on this subject, *Physiocratie, ou du Gouvernement le plus avantageux au genre humain*, was first published in 1768. Not only had the speculations which he broached, and which he propagated with much fervour and diligence, considerable success in the world, but he had the fortune to gain a considerable number of proselytes, who exerted themselves with an ardour for the diffusion of his doctrine, and with a devotion to the opinions of their master, which more resembled the enthusiasm of the votaries of a new religion, or that of the followers of some of the ancient philosophers, than the indifference with which new speculations in philosophy have on all other occasions been received in modern Europe; and which gave to the economists more of the character of a sect or a school, than has appeared to belong to those who have in recent times concurred in any other system of philosophical opinion.

There was, in truth, in the system of M. Quesnay and the other economists, many things well calculated to attract attention and excite enthusiasm. From a few simple principles, they deduced, as they imagined, by a chain of very close and imposing arguments, a system of changes which would easily be introduced, without the smallest interruption to the tranquillity and happiness of the existing generation, calculated to remove from society all the deformities by which it was overspread, and to communicate to the mass of human beings a fulness of happiness hitherto altogether unknown. At this point, therefore, we may close the historical part of this article; for the success of the great work of Dr Adam Smith, in a short time, superseded the *political economy* of the sect; and after the political economy was discredited, the rest of their doctrines met with little regard. The memory of them, however, is well worthy of being preserved; and this task we shall now, in as few words as possible, endeavour to perform.

II. The economists proceeded upon no Utopian plan, which supposes society to be composed of beings different from those with whom we are already acquainted. They took man as he is, a being having wants, and governed by the desire of avoiding pain and obtaining pleasure.

Man must have subsistence. Upon this ground they first took their stand. This being allowed, it followed, of course, that whatever was the best means of obtaining subsistence, would command the operations of men as soon as ever it was sufficiently known.

Of these means, the first and fundamental is the establishment of property. This they proved by convincing arguments. We cannot exist without consuming. The nature of man leads to a rapid multiplication of human beings, and the earth yields a spontaneous nourishment for only a few. To make food keep pace with population, labour must be employed upon the ground. Men would be born for no other purpose than that of destroying one another, if there were not means of increasing the quantity of food in proportion to those that were born. Labour, then, is one of the physical necessities of nature. But if labour be necessary, so is property, because, without property, there can be no labour.

The proof of this proposition is short and irresistible. Nobody would labour under an assurance that he would derive no advantage from his labour. Nobody would labour without a certain probability that he should enjoy the fruits of his labour. Now, this is property. The only question, then, which remains is, what is the degree of assurance with respect to the fruits of a man's labour; in other words, what are the laws of property which tend most to secure the benefits which human beings derive from their labour? This, said the economists, is the object and the end of our researches.

They proceeded in their inquiry by the following steps. As a means to this labour, on which every thing depends, a man must be free to use his natural faculties of labour —his muscular powers. This freedom they called *the property of his person.* As another means to the same end, he must be free to use exclusively, and to preserve, what he acquires by his labour. This they call his *moveable property.*

Here we see the origin of that to which men have assigned the names of *rights* and *duties.* The exclusive powers assigned to the man over his person, and over the fruits of his labour, are called his *rights.* To allow these exclusive powers, by abstaining from every act which would impair them, is called the *duties* of all other men. Here we see, also, that *rights* and *duties* are reciprocal; that they imply one another, that they are created together, and that the one cannot exist without the other. Destroy the *rights* of property in the man, you destroy, by the same act, the *duties* of other men to exclude themselves from what was called his property. Destroy, in the same manner, the *duties* of other men to exclude themselves from what was called his property, and you destroy, at the same time, his *right* to that exclusion. *Rights* and *duties* are, in fact, but different names given to the same thing, according as it is regarded under one or another of two points of view.

Another important concatenation is here also to be seen. *Rights* are advantages; things to be enjoyed. *Duties* are burthens, abstracted from things to be enjoyed. Why should men accept these burthens, submit to these duties? Why, but because they find their advantage in doing so. It is plain how they find their advantage in doing so, and there is, there can be, no other reason. Men submit to the *duties* of respecting other men's *rights,* that they may have *rights* themselves. It is good for them to have *rights;* there can be no rights without *duties.* It is better to have the *rights* submitting to the *duties,* than, by renouncing the *duties,* to have no *rights.* The *duties* are then the price which is paid for the *rights.* The *duties* which one man yields to other men, are the price which he pays for having *rights* of his own. *Duties,* then, are in themselves *evils;* and they never ought to exist, except when they are compensated by a greater good. Nobody ought to be subjected to a burthen, which is not, either to himself, or to the community in which he has clubbed his private interests, attended with a good sufficiently great to overbalance the evil which he is made to endure. *Utility,* then, is the exclusive foundation of *duty.*

Having laid this foundation, the economists proceed.

On the necessity of subsistence rests the necessity of property, and on the necessity of property rests the necessity of a certain inequality in the conditions of men. This inequality exists, because a good is obtained through it, which can in no other way be obtained; and that good the parent of every thing else to which the name of good is applied. " Those who complain of it," says Mercier de la Riviere, one of the chief expositors of the doctrines of the sect, " see not that it is a link in the chain by which the human species must drag from the abyss of non-production every thing which they enjoy. As soon as I have acquired the *exclusive* property of a thing, another man cannot have the property of it at the same time. The law of property is the same for all men; each man, however, acquires in proportion to his faculties of acquiring: but the measure of these is different in different men. And besides this fundamental law, there is, in the whirlpool of accidents, a continual succession of combinations, some more, some less fortunate, which increase the causes of that inequality of acquisition, without which the motives to acquisition cannot exist.......................I admit, however," he in conclusion adds, " that in any given community, these differences in the possessions of different men may become the source of great disorders, and which augment again these same differences beyond their natural and necessary degree. But what follows from this? That men ought to establish an equality of conditions? Certainly not; for to that end, it would be necessary to destroy all property, and, by consequence, all society: it only follows that they should correct those disorders which make that which is an instrument of good become an instrument of evil: which alters in such a manner the distribution of things, that *force* places all the rights on one side and all the duties on the other."

We have seen that the necessity of labour to procure the means of life and the means of enjoyment, produced a necessity of *property personal* and *property moveable,* as the two sorts were named by the economists. The necessity of raising food, as well as the first material of most of the other articles of human enjoyment, by labour upon the *land,* produces a like necessity of creating a *property in the soil.* The proof of this proposition is not less short and convincing than that which regards the other species of property. To make the land yield a produce useful to man, it must be cleared of many incumbrances, and prepared with much labour and expense. No adequate return can be obtained for this labour to the man who would bestow it, without a perpetuity of possession. It is essential for the well-being of the species that the labour should be yielded, and in the greatest degree of perfection. It cannot be yielded perhaps at all, certainly in no tolerable degree of perfection, without that exclusive possession which constitutes property. Property in land is, therefore, essential to the well-being of the human species.

We see in this manner what are the *rights* and what are the *duties* which the supply of the first wants of human nature renders it necessary to constitute; but as all mankind are not disposed to respect *rights* and *duties,* it is necessary, in order to obtain the advantages which they are destined to produce, that measures should be taken to protect them.

The measures taken to protect them are generally com-

prehended under one name, that is, *government*. The protection of the rights, or, which means the same thing, the insuring of the duties, is the *end*, the government is the *means;* and the question is, what combination of means is best adapted to the purpose?

This assuredly is the most important question to which the human faculties can be directed; and the economists have never yet received the credit which is their due, for the ability and success with which they laboured to resolve it. No speculations can be conceived of more importance than those in which they engaged, nor has it yet become easy to throw upon them a greater portion of light.

The grand classes of means by the skilful combination of which they conceived that the end might be obtained, were either more direct or more indirect. The more indirect were liberty and evidence; the more direct were laws exactly adapted to the end, magistrates exactly adapted to the execution of these laws, and a supreme, or, as they called it, "*tutelary power*." We shall endeavour to communicate their leading ideas on each of these particulars.

1. *Liberty*. We have seen that the end which is aimed at through property, as a means, is the greatest possible abundance of the things adapted for human enjoyment, and that property is a means altogether indispensable for that end. It is now to be proved that liberty is absolutely necessary to enable property to answer the purpose of a means to that end, and that, without liberty, the existence of property is deprived of almost all its advantages. In fact, the right which a man has not the liberty to enjoy is not a right. The right of property in a man's person, in his moveables, in his land, is the right of enjoying; but the *right* of enjoying and the *liberty* of enjoying are the same thing. Liberty, therefore, cannot be hurt without damaging the right of property, and the right of property cannot be hurt without damaging liberty. "It is," says Mercier de la Rivière, "so inseparably connected with the right of property, that it is confounded with it, and that the one cannot exist without the other. Deprive a man," he cries, "of all the rights of property, and I defy you to find in him a vestige of liberty. On the other hand, suppose him deprived of every portion of liberty, and I defy you to show that he truly retains every right of property."

It is now pretty clear that liberty is necessary to produce that abundance of production which is the end aimed at by the constitution of all *rights* and *duties*. Man is excited to labour only in proportion as he is stimulated by the desire of enjoying; but the desire of enjoying can only be a motive of action in so far as it is not disjoined from the liberty of enjoying. You cannot have productions in abundance, without the greatest possible inducement to labour; you cannot have the greatest possible inducement to labour, without the greatest possible liberty of enjoyment. The chain of evidence is therefore complete.

"Let us not," say the economists, "seek in men beings which are not men. Nature has destined them to know only two springs of action, or moving powers; the appetite of pleasure and the aversion to pain. It is in the purpose of nature, therefore, that they should not be deprived of the liberty of enjoying, since, without that liberty, the first of those two powers would lose the whole of its force. *Desire of enjoying, liberty of enjoying;* these are the soul of the social movements, these are the fruitful seed of abundance, because that precious combination is the principle of all the efforts made by human beings to procure it."

2. *Evidence*. Property, and by consequence liberty and security of enjoying, being proved to constitute the essence of what they called the natural and essential order of society, it was seen to be in reality a chain of *physical* consequences, involving nothing arbitrary, nothing changeable; evident, on the other hand, simple, and resting on no other ground than that of being the most advantageous possible to the whole body of the community, and to every one of its members.

"The best possible order of society, however," they observed, "cannot be established where it is not sufficiently known; but for that very reason, that it is the best order, the establishment of it, as soon as it is known, must become the common ambition of men; it must then introduce itself by *necessity*, and, once established, it must by *necessity* continue for ever." These were bold promises, but the proof was correspondent. "The best possible order of society must introduce itself as soon as known, and preserve itself for ever as soon as introduced, because the appetite of pleasure, and the aversion to pain, the only moving powers within us, lead naturally and constantly toward the greatest possible augmentation of enjoyments; and the desire of enjoying implies by necessity that of the means by which enjoyment is procured. It is, then," said the economists, "impossible that men should know their best possible condition without a consequent union of all wills and all power to procure and to preserve it. Imagine not," they cried, "that for the establishment of this essential order it is necessary to change the nature of men, and divest them of their passions; their passions, on the other hand, become auxiliaries in this establishment, and, for the most complete success, it is only necessary to place them in a condition to see with *evidence* that it is in this order alone they can find the greatest possible sum of enjoyments and of happiness."

These philosophers made some admirable observations upon the nature of evidence, and the important purposes to which it is subservient. They made a distinction between those propositions which a man receives without evidence, and those which he only receives upon the strength of evidence. The first they denoted by the word *opinion*, the second they marked by the names of *knowledge* and *certainty*. "As error," they said, "is every thing which is not truth, in like manner, what is not *evidence* is only *opinion;* and whatsoever is only opinion is arbitrary, and liable to change. It is evident, therefore, that these opinions are not a sufficient foundation for the natural and essential order of societies. A solid edifice cannot be erected on a basis of sand; and that into which nothing arbitrary can enter, which is and must be unchangeable as the ends to which it is directed, can never be founded on a principle so arbitrary and various as opinion; opinion which, however just and true it may accidentally be, so long as it is not founded on evidence, is but opinion still, and liable every moment to be subverted and expelled by any other opinion, however extravagant and absurd."

Evidence is the knowledge, clearly attained and possessed by ourselves, of all that is necessary to see the truth or falsehood of an object of belief. This excludes all doubt, all uncertainty, every thing arbitrary, all exercise of will. A man can no more help believing that which he actually holds in his mind evidence sufficient to prove, than he can help seeing the object which is painted on his retina.

From this irresistible power of evidence the economists deduced the most important consequences. "Not only is it," they said, "the essential characteristic of evidence to stand the test of the most severe examination, but the most severe examination can have no other effect than that of displaying it to more advantage; that of giving to

it a power more predominating and supreme; while, on the other hand, sufficient examination destroys prepossession and prejudice, and establishes in their place, either evidence, or at least suspension of judgment, where evidence on which to found a judgment is out of our reach."

On the first of these propositions, that "evidence can stand the test of the most severe examination," they said, "that all attempt at proof was surely unnecessary,—it was self-evident; and hence," they said, "was evidently deduced this most important consequence, 'that the liberty of examining, of criticising, and of contradicting evidence, is always and necessarily without inconvenience.'"

"That a sufficient examination destroys prepossession and prejudice," they regarded as a proposition equally indisputable; and from this it followed, as an irresistible consequence, "that the most unbounded liberty of examination and contradiction is of primary and essential importance; for no examination can be *sufficient* till all the reasons of doubt are exhausted."

"That a sufficient examination establishes evidence in the place of error in the case of all questions where evidence is within our reach," was a truth, they said, resting on the same immoveable basis; and from this it followed, as an evident consequence, "that liberty of inquiry will lead by necessity to the clear and public knowledge of what is the best possible order of human society; for on this subject evidence is undeniably within our reach."

"We may thus regard evidence as a sort of beneficent divinity, whose pleasure consists in spreading peace on earth. Never do you behold mathematicians at war with mathematicians on account of the truths which they have established on evidence; if they enter into a momentary dispute, it is only while they are yet in the avenue of inquiry, and have investigation solely in view; but as soon as evidence has pronounced either on the one side or the other, every man lays down his arms, and only thinks of enjoying in peace the good which is thus acquired in common."

"Pass now," say the economists, "from the evidence of *mathematical* to that of *social* truths; to the evidence of that order of human affairs in society which would produce to men the greatest possible amount of happiness. From the known effects of evidence in the first of these cases, try to conceive what would be the effects of it in the second; what would of *necessity* be the internal condition of a society governed by that evidence; what would of *necessity* be the political and respective situation of all nations if they were illuminated by its divine effulgence; consider if men, rallied under the standard of that evidence, would have any division among them; if any motive for war would be sufficiently powerful to make them sacrifice to it their best, and to themselves *evidently* best possible condition: penetrate still deeper, and see if the pictures which that medium presents to you do not excite in you sensations, or rather transports, which elevate you above yourself, and appear to indicate that, by means of evidence, we communicate with the divinity.

"But to increase your sensibility to the impressions which those pictures will make upon your understanding and your heart, place in opposition all the inconveniences which, in a state of ignorance, arise from the force of *opinion.*

"A certain thing is forbidden under the sanction of punishments capable of inspiring the greatest terror. What power can such prohibition and punishments have against an opinion which tends to despise them? None; we have too many examples to prove it.

"A man is placed by his birth in a situation in which he might effect the happiness of a great number of other men, if he made a beneficent use of his advantages; what is it the man performs when his *opinion* is wrong? He sacrifices his advantages to the disorder of his opinion, lives and dies unhappy.

"One man unarmed commands an hundred thousand with arms in their hands, of whom the weakest is stronger than he. What constitutes his power? Their opinion; they obey him in obeying it; they follow their leader because they have an opinion that they ought to follow him.

"Do you wish to see other effects which characterize the force of opinion? Consider the effects of honour; of that sort of enthusiasm which prefers toil and fatigue to repose, poverty and privation to riches, and death to life, on which it finds the secret of shedding a lustre.

"*Opinion*, of one sort or another, governs the world. Even when it is but a prejudice, an error, there is no power in the moral world comparable to its power. Fruitful in phantoms, it borrows all the colours of reality, in order to deceive. Source inexhaustible of good and of evil, it is through it alone that we see, by it alone that we will and we act. According as it borders upon truth or falsehood, it produces virtues or vices, the great man or the villain. No danger stops it; difficulties render it more intense; at one time it founds empires, at another destroys them.

"Every man is therefore a little kingdom upon the earth, governed despotically by opinion. He will burn the temple of Ephesus, if it is his opinion that he should burn it; in the midst of the flames he will brave his enemies, if his opinion is that he ought to brave them. Our physical powers themselves are so completely subordinate to the power of opinion, that, to have the command of our physical powers, it is necessary to begin by having the command of our opinion; but how is it possible to have the command of opinion, while it is the sport of ignorance, and its nature arbitrary? How is it possible to fix and to unite the opinions of men, but by the agency of evidence? Is it not visible that the Author of nature has appointed no other means for chaining our arbitrary will?

"We ought to look, therefore, upon ignorance as the necessary principle of all the evils which have afflicted society; and upon the knowledge, that is, the evidence of the best possible order of society, as the natural source of all the good which is destined for the inhabitants of the earth.

"But as all the physical forces in the world cannot render that evident which is not so, and as evidence can spring from nothing but *adequate examination*, from the necessity of that evidence clearly follows the *necessity of examination*, from the necessity of examination clearly follows the necessity of the *greatest possible liberty of contradiction*, and, in addition to that liberty, the existence of all those political institutions which are required to give to evidence its greatest possible *publicity*."

The *publicity of evidence* was a subject on which the economists dwelt with peculiar emphasis, and which they branched out into a number of the most important consequences. "The necessity of it," they said, "was apparent from this, that the proper order of society cannot be solidly established, but in proportion as it is sufficiently known. In any society, if some men only had knowledge and evidence of this order, while the multitude rested in other opinions, it would be impossible for this order to govern; it would in vain command; it would not be obeyed. This state would be that of a perpetual intestine war of one part of the nation with another. By *intestine war* they did not, however, mean," they said, "only that which is performed with arms in the hands, and by open force; they more peculiarly referred to those disguised and clandestine ravages and oppressions exercised under forms of law; to those dark and predatory practices, which sacrifice all the victims which artifice is able

to bring within their power; to all those disorders, in a word, which tend to make all particular interests enemies of one another, and thus to uphold, among the members of the same political body, an habitual war of clashing interests, the contending effects of which tear in sunder all the bonds of society. This situation is so much the more dreadful. in as much as, excepting the superior and governing force of evidence, there is no power in nature equal to that of opinion; as in its aberrations opinion is tremendous, and as no means exist by which we can make sure of retaining it always within proper limits, when it is once given up to its own inconstancy, and to seduction.

" From the *publicity*, which is an indispensable condition to possession of evidence respecting what is best in the social order, we are conducted to the necessity of *public instruction*. Though faith," said the economists, " be the gift of God, a peculiar grace, which cannot be the work of men alone; nevertheless it is held that the preaching of the gospel is peculiarly necessary to the propagation of the faith. Why, then, should not every one have the same opinion with regard to the publication of the social order, more especially as that publication has no need of being aided by grace and supernatural light? This order is instituted for men, and all men are born to live under it; it is then required by this order that men should know it, and accordingly they have all a sufficient portion of natural faculties, to be able to elevate themselves to that knowledge. For the same reasons that knowledge is required, instruction is required, by which alone certain kinds of knowledge can be attained."

The economists did not enter into details respecting establishments necessary for instruction. They, however, affirmed, that such establishments " constituted a part of the essential form of a society, and that they could hardly be too numerous, because instruction can never be too common." They affirmed, also, that " verbal instructions did not suffice; that it was necessary to have doctrinal books, suited to the purpose, and in every body's hand. This help," they said, " was so much the more important, as it was clear of all inconvenience, for error cannot stand in the presence of evidence; and contradiction is not less advantageous to evidence than it is fatal to error, which has nothing to fear so much as examination."

What they affirmed with respect to the necessity of those which they called doctrinal books, and of the liberty which ought to reign with regard to them, " was founded," they said, " upon the very nature of that order which is due to society, and of the evidence which belongs to it. That order," they observed, " is either perfectly and evidently known, or it is not. In the first case, its evidence and simplicity render the formation of heresies on the subject of it altogether impossible. In the second case, men cannot arrive at knowledge or evidence, but through the conflict of opinions. It is certain that an opinion can be established only upon the ruins of those which are opposed to it; it is further certain, that every opinion which is not founded upon evidence will be contradicted, until it is either destroyed, or recognized on evidence for a truth, in which case it ceases to be a bare opinion, and becomes an evident principle. And thus, in the pursuit of truths, capable of being established on evidence, the conflict of opinions leads, of necessity, to evidence, because it is by evidence alone it is capable of being terminated."

This doctrine is of such infinite importance, that we are willing to prolong it, by adding the illustration which the economists were accustomed to adduce. " If a man should be actuated by any motives to write a book endeavouring to persuade his countrymen that they might live without subsistence, that they ought to make commodities without the materials, that they multiply themselves by change of place, or any other extravagant opinion, it would be highly useless for the public authority to give itself any concern or labour to prevent such a book from making an impression upon the public mind; and, far from feeling any alarm, every body would rest securely upon the evidence of the contrary truths, assured that this evidence would always be sufficient for itself, and would quietly triumph over all the ridiculous efforts which would be made to oppose it.

" So absolutely necessary is it to leave to the whole body of society the greatest possible freedom of examination and contradiction; so absolutely necessary is it to abandon evidence to its own strength, that there is no other power which can supply its place; physical power, of what magnitude soever, can command actions alone, never opinions. The experience of every day affords to this truth the evidence of the senses. So little have our physical powers any influence over our opinions, that our opinions, on the contrary, exercise an uncontrollable dominion over our physical powers. Our physical powers are put in motion, and guided by our opinions alone. The common or social, called the *public force*, is formed by the union of the physical powers of many individuals. This supposes, necessarily and invariably, a correspondent union of evils; and this can never exist but in consequence of an union of opinions, good or bad. It is, therefore, to reverse the order of things, and take the effect for the cause, to desire to give the public force a power over opinion, while it is from the union of opinions that public force holds its own existence, and while, by consequence, it can have no stability but in proportion to that which reigns in the opinion on which it is founded, that is to say, in proportion as bare opinions, stripped of evidence, are replaced by opinions fixed and invariable, because founded upon evidence which cannot deceive."

3. *Laws*. Having established as incontrovertible truths, that property is necessary to the production of the means of human life and enjoyment, that the system of human rights and duties spring from it as natural consequences, and that the natural and essential order of societies is nothing in reality but the chain or connected order of these same rights and duties, the economists laid down the following definition: " That the essential form of a society is the continuation of all those social institutions which are necessary to consolidate the right of property, and secure to it all the liberty which essentially belongs to it."

Among these instrumental establishments, an important place is held by laws, of which they communicated the following very striking and original idea.

" A multitude of men assembled without acknowledging any respective rights, any reciprocal duties, would not form a society. That does not consist in the meeting of a number of men in a particular place. It may subsist among men very remote in respect of place, and not subsist among men very near in respect of place. *That which really constitutes the union, are the conditions of the union.* These conditions are the systems of rights and duties, in other words, the conventions entered into for their common interest by the members of the associated body. The laws, then, are precisely those conventions, by operation of which, the reciprocal rights and duties are established in such a manner that the members of the society are no longer permitted arbitrarily to depart from them.

" Of these conventions, some are of such a nature as cannot be defined very exactly, or at least cannot be enforced by artificial sanction, but must be left to the natural coercion of the approbation and disapprobation of mankind. Such are the common duties of morality; gratitude, veracity, charity, and the like. But the next class

of these conventions are those which are capable of being defined exactly, and enforced by artificial sanctions; as, that murder shall not be committed, property shall not be stolen. This last class of conventions are those which are properly called *laws*.

"The first property necessary to give those laws their best possible *form* (for, in regard to their substance, it is always supposed that they are strictly conformed to that utility from which the whole system of rights and duties takes its origin) is, that they be definitive; to distinguish, by an incontrovertible line, what each of them does, from what it does not, comprehend. This is implied in the very notion of a law, which is to render something *positive*, which would otherwise be *arbitrary*.

"The second property necessary to give laws their best possible form is, that they be written. This is indeed implied in the first property; because no combination of ideas can be rendered *positive* and *unvarying*, of which the *expression* is not *positive* and *unvarying*. But nothing can render an expression positive and unvarying but a permanent sign; and, of permanent signs, none is equal to writing.

"The third property necessary to give to laws their best possible form is, that the reason of each be annexed to it. The distinction is very important between the *letter* of the law, and the *reason* of the law. The *letter* of the law is its textical composition; the *reason* of the law is the motive by which it was dictated. *The man who is guilty of murder shall receive a certain punishment.* This is the *letter* of the law. The *reason* is, that *if murder were common, and not restrained by adequate motives, the happiness of human beings, if not the species, would soon be destroyed.* Having thus acquired a knowledge of the reason of the law, I possess the *evidence* of its *utility*. And of this I should not have been possessed, had I seen in the law nothing more than the *letter*. Let us suppose two laws, which equally assign the punishment of death; the one for homicide, the other for walking at certain hours in the day. Is it not clear that they would be viewed with different eyes; that the one would appear to be just, the other tyrannical; that we should feel within ourselves a natural disposition to submit to the one, a disposition to avail ourselves of every thing which might serve as a means to deliver us from the hateful yoke of the other? This difference arises from the different judgment we form of the *reason* of these bad laws. The first carries with it the *evidence* of its *utility*; and that *evidence* overcomes and binds without resistance the understanding and the will. The other carries with it, instead of the evidence of utility, the evidence of nothing but a disproportional rigour, of a manifest evil, to which our understanding, and consequently our will, can never submit.

"It is not, therefore, in the *letter*, but in the *reason* of the laws, that we must seek for the first principle of a constant submission and obedience to the laws; for that principle can be nothing but the dominion exercised over our minds by the *evidence* of the justice of necessity, that is, the *utility* of the laws; now this evidence is not in the *letter* of the laws; to establish that submission, therefore, generally and invariably, two conditions are requisite; one is, that the reason of the laws contain conclusive *evidence* of their *utility*, commonly called their justice and necessity; the other is, that the publication of this evidence be so complete, in respect both of clearness and diffusion, as to lodge it in the mind of a majority of all classes of the people. Men, persuaded that their laws were bad laws, might indeed for a time be constrained to observe them; but such a submission, contrary as it is to nature, could not be durable, nor escape daily breaches on the part of those who regarded themselves as suffering by the injustice of the laws. *Submission to the laws is always, and necessarily, proportional to the idea which we hold of their justice and necessity;* that is, their indispensable use in procuring good and eschewing evil.

"If laws," said the economists, "are any thing but the results of the natural order of society, or of that system of duties and rights which are rightly founded upon the interest of all; if the legislature of any country sets up rights and duties of another sort, these new rights and duties are contrary to the first; and hence, of necessity, the laws which prescribe them are in a state of perpetual opposition with our understandings and wills." This contrariety they proved in the following manner: "All the rights which a reasonable being can desire are summed up in that of property; because from the right of property results the liberty of enjoying; a liberty which ought to have no bounds but those which are assigned to it by the similar rights of property belonging to other men. As the essential order of society thus determines the measure of liberty belonging to each of its members, and as that measure is the greatest which can be, without disturbing that essential order itself, it is impossible that any thing should be added to the liberty, that is, to the rights of one set of men, without taking from the liberty, and by consequence from the property, of other men; and this is an injustice and disorder, the tendency of which is destructive to the society."

It is destructive to the society, because it throws it into a state of violence. "My neighbour," says Mercier de la Rivière, "will be content that he is not allowed to reap or to injure my crop; but for the same reason he will not be content that I should be allowed to reap or to injure his. On the view of such an injury permitted in regard to any other man, he will take the alarm, his fears will be excited for himself, and this anxiety will be a state of torment, from which his reason will perpetually urge him to seek relief. A law which violates the principle of utility, is a law therefore resisted by that evidence which governs beyond control the human will. To make such a law, is to put the society into a state of violence, because it is to put the minds of men into a state hostile to one another, and more or less hostile to the laws.

4. *Magistrates.* By this term the economists understood judges, and, in a word, all the leading functionaries employed in giving execution to the laws. Agreeably to the doctrines already exhibited, they conceived that the first service of the magistrates is that of shedding the light of *evidence* upon the particular cases which have been too obscure for the parties. But as there are some minds with which you cannot be sure of being able in every case to bring evidence, as it were, in contact, the magistrate needs to be armed with a coercive power; and all that is necessary is, that he affords to the rest of the community *evidence* that in such cases the power has been used agreeably to the principle of general good.

From these premises, the chief consequence which they deduced was, that the legislative and judicial powers are never to be united in the same hand, without destroying among the people all certainty of the justice and necessity of their laws, that is, the very essence of the laws themselves.

"The essential form of positive laws," they said, "in that which makes them to be what they ought to be, is, that they consist of certain visible signs, which show, that in the institution of them, that order has been followed which is necessary, 1*st*, to ensure their justice and necessity, that is, their adaptation to the ends of obtaining good and avoiding evil; 2*dly*, to render their adaptation to those ends evident or certain to the individuals whom

they concern. Now it is clear that these conditions could not be fulfilled if the legislative power was to engross the judicial functions. The legislator and judge being the same person, neither could the legislator find any resource against his own mistakes in the close review and experience of the judge; nor, on the other side, could the arbitrary will of the judge find any bridle or chain in the authority of the legislator; but the laws, however good in themselves, would be rendered evil by a variable and corrupt administration.

"If the legislator were judge also, his business would be to consummate and to crown all the mistakes which he incurred, or the abuses which he committed, in the formation of the laws. If the judge were legislator also, the laws existing only in conformity to his will, he would be under no necessity to consult the laws in passing his judgment, and would always ordain as law-maker, what he should have to determine as law-interpreter. Thus the *reason* of the positive laws would be found to consist in nothing but the will of the legislator, as he would be guided in making them by nothing but its arbitrary impulses; and, in the same manner, the *reason* of the judicial decisions would be found to consist in nothing but the mere will of the judge, whose independence would enable him to make them whatever he pleased. This double malady abundantly proves that those laws would be stript of the essential characteristics of law, the evidence of their justice and necessity, and an absolute exemption from every thing arbitrary."

The duties of the judge they deduced in the following order: As the laws are in themselves mute, and the magistrate is the organ through which they speak, he is particularly charged with the *guardianship* of the laws. It is of importance to know what is implied in the term guardianship of the laws. It relates either to the laws which *are* made, or to those which are *to be* made. The natural strength of the laws consists in the evidence of their goodness. Their weakness consists in the strength of the hands which dispose of the physical power. As the laws are mute in themselves, they cannot wield that evidence in which their strength consists. The magistrates, who are the mouth of the laws, ought therefore to wield it for them, and to resist the hands in which the physical power is deposited, when they attempt the infringement of the laws, with all the force which evidence can be made to exercise over the minds of the community.

The same principles demonstrate what are the duties incumbent on the depositaries of the judicial power with regard to laws *to be* made. As laws ought all to be founded on that concatenation of the causes of human good which the economists denominated "the primary and essential reason of all laws, the *evidence* of that primary and essential reason was," they said, "a deposit, so to speak, in the hands of the judicial instruments, of which they owed an account to the legislature, to the nation, and to God himself, of whose supreme will that evidence is the decisive token. It was their first duty, therefore, to have a perfect *knowledge* of that primary and essential reason." Their next duty was, on all occasions, as far as their utmost efforts could extend, to impart that evidence to the governing power, and to make it as clear as it can be made, what laws, not yet proposed, that evidence shows that the society requires.

The economists further affirmed, "that no man can, without rendering himself criminal towards earth and heaven, undertake to perform the office of judge, according to laws that are *evidently* unjust. He would in that case cease to be a minister of justice, in order to become a minister of iniquity. If any law, for example, ordained that a man should be condemned to the ultimate punishment, on the mere denunciation of another man, and without any inquiry into the truth of the allegation, is it not evident that such a law would be a law of murder? And is it not equally evident, that the barbarian who should pronounce a judgment agreeably to that law, would be the voluntary instrument of murder? It is necessary, however, either to go the full length of saying that a man can, without guilt, become the instrument of such a law, or allow that no minister of the law ought to lend his ministry to the execution of a law evidently unjust; for if he may for one such law, so he may for all, however atrocious; no outrage to humanity, no excess of evil, presents any limiting point."

5. The *tutelary authority*. "The union of wills to form that of individual powers; the union of individual powers to form a common or public force; the deposit of that force in the hands of a chief, by whose ministry it may command, and make itself obeyed,—these," said the economists, "are the component parts of the tutelary authority. The tutelary authority is nothing more than a physical force resulting from an union of wills; and, by necessary consequence, it is impossible for it to be either powerful or secure, unless the intuitive and determining force of evidence be the principle of that union.

"In one sense, it may be affirmed that the right of commanding belongs to evidence alone; for, in the order of nature, evidence is the only rule of conduct bestowed upon us by the Author of nature. But all men are not equally capable of seizing evidence; and even if they were, the interest of the moment often operates upon them with such vehemence, that the appetite of enjoyment will not, in a state of disorder, be restrained by the evidence of duty. Among human beings, therefore, it is necessary that the natural authority of evidence be armed with a physical force; and that the legislative power, though it commands in the name of evidence, have the disposal of the public force to ensure obedience to its injunctions."

From the analysis of what is necessary to constitute the tutelary authority, the key-stone, as it were, of the arch of human society, that which gives to the whole its binding force, and retains the parts in their order, the economists deduced a variety of most important conclusions, of which we can only present the more striking as a sample.

The first is, that the legislative and executive powers are essentially inseparable, and that all the fine-looking theories, which have solicited and obtained so much of the admiration of a superficial world about the virtues of their separation, are phantoms in the air, the mere visions of imagination. "To dictate laws is to command; and as our passions render it impossible that commands should be more than useless sounds without the physical power of making them obeyed, the right of prescribing laws can have no existence without the physical power of enforcing them. The depositary of the power is, therefore, and necessarily, the master of the right; and the executive power is always and certainly the legislative power. Let the enemies of this conclusion turn and torture the subject which way they please, they never can escape from it. Suppose, in order to form two powers, that the legislative right is confided to one organ, the public force to another, when opposition arises, which of the two is to be obeyed? As it is impossible that two contradictory commands can be obeyed at the same time, it must be absolutely decided which of the two is in preference to be obeyed. Now, this decision is, by the very fact, the destruction of the other power, and the establishment of that one. These two powers, therefore, unavoidably run into one; the legislative power necessarily becomes the executive power, or the executive becomes the legislative.

The second is, that the legislative never has, never can have, a right to make *bad* laws. A right to make bad laws, they said, is a contradiction in terms. A right supposes a *compact;* it is the offspring of an agreement, tacit or express; the idea of it can no more exist without that of a mutual convention, than a debt without the contract of debtor or creditor. The compact upon which all rights are founded is that of mutual advantage; it is the union of all wills, freely determined by a great interest, of which the *evidence* is visible to all. How can that union which only exists for the sake of a good continue to exist if it is seen to produce evil? The hope cannot be framed of maintaining it by force, because force is its effect; force can exist only subsequent to union, and in consequence of union. The horrid prerogative of being able to make bad laws supposes necessarily a state of ignorance, a state in which the vices of the laws are not illuminated by evidence; for it is impossible that a community should consent to uphold that which visibly hurts them. The power exists in this hateful situation, but the right as little there as anywhere else.

The economists come next to the important question, What is *the security for the right use of the legislative power?* On this subject their anxiety to secure to their opinions the benefit of publicity, and the favour of those in whose hands the governing powers were actually deposited, led them to use the veil of expressions too general, and into some positive mistakes. "The security," they said, "for the right use of the legislative power, is the interest of that same power, which can, in the general order alone, find its own best possible state The irresistible force which evidence acquires by publicity is also that security. This evidence exists in its greatest force in the body of the magistrates, who cannot, without ceasing to be ministers of justice, lend their ministry to the execution of laws evidently unjust; or forbear, without being criminal, their utmost endeavours to make the *evidence* of that injustice as clear as possible both to the legislature and to the nation."

The grand question followed, *What are the hands in which the legislative power ought to be deposited?* Having demonstrated that the legislative and executive powers cannot by possibility exist in any but the same hands, and that they form together what they denominated the *tutelary authority,* they proceeded to inquire what was implied in the idea of authority. "Unite," said they, "upon one object a multitude of opinions and of wills; from that union will arise naturally and necessarily an union of physical forces for the accomplishment of those wills; and from the whole together will result an authority, or, in other words, *a right of commanding, founded upon a physical power of procuring obedience to what is thus commanded.* If these opinions and wills should disunite, and form, for example, two parties, the forces will for that reason be divided; there will be two forces, two authorities, and, by consequence, two societies. That two authorities cannot exist in the same society, they maintained by the following proof. Such authorities must be either equal or not equal. If equal, each of them taken separately is null. If unequal, the superior is the real and only authority. That, in the first case, each taken separately would be strictly and literally null, arose, they said, from the very nature of equality, which rendered it absolutely impossible that the one could do any thing without the other. Neither of them, therefore, could procure a single act of obedience, except by their union; but, at the very moment of their union, they cease to be two authorities, and form both together only one authority made out of the union of both. Unity is, then, a part of the very essence of authority; to divide it is to reduce it to an incapacity of acting, that is, to extinguish it; for authority is not authority but in so far as it can act to procure the execution of its will."

From the necessary unity of the tutelary authority it followed, they said, by necessary consequence, that the organ of that authority must be one man. That the physical force which is one of its component parts can be directed only by one will, is above the need of proof. But it is said that one will may be formed out of the union of several wills, and that the public force is not subject to the separate wills till the union takes place.

To this the economists made answer, that if the opposition of one will can suspend the effect of all the others, it reduces authority to inaction, and for that reason destroys it. The reason why physical force is necessary is, that you cannot count upon the union of all wills. If, to avoid this objection, you have recourse, they said, to plurality of suffrage, you build no longer on the basis of evidence. That which divides opinions is not yet evident. As nothing in government ought to be arbitrary, and every thing that is not arbitrary is founded on reasons, that is, *evidence,* there cannot be diversity of opinions on matters of government, except from the effect of ignorance, or of bad design on the part of the deliberants. But it cannot be determined by a few voices less or more, on which side the ground of evil lies. Experience shows that an accredited error may long unite partizans in much greater number than the truth by which it is opposed. The number of those who concur in an opinion cannot render that evident which is not evident; their opinion is only opinion still, which is of course subject to change; for nothing but evidence is unalterable. And with respect to bad design, as that results from particular interests, it can never be determined whether the number of those whom such interests command is the greatest or the least. On both accounts, then, plurality of suffrage is not security.

But the greatest evil, they said, of the mode of determining, by majority of votes, the question respecting the social order, was, that it set individual interest in opposition to public; in which case the public interests are sure to be sacrificed. "How great soever the differences among men, they have within them, nevertheless, two grand moving powers common to all, and which are the source of all their actions—the appetite of pleasure and the aversion to pain. To suppose that men can move in opposition to those powers, is to suppose that the cause can depend upon the effect. But the desire of enjoyment, and opinion by which it is modified, cannot act naturally and constantly in the direction of the public interest, when authority is divided among several persons who are liable to have interests opposite to one another. For it may be laid down as a truth which will not admit of contestation, that the public interest cannot be considered as generally safe when it is in opposition to the private interests of those who are entrusted with it. If one or more of the public administrators behold any great advantage to themselves in a sacrifice which has been made, or which may be made, of the public interest, we ask, said the economists, What can prevent the sacrifice from being made? Not the two springs of action which nature has placed within us to be the cause of all we do; for they are in this case put in opposition to the public interest. Not any other authority in opposition to that of the public administrator, since by the supposition they themselves engross the whole of the governing power."

The remaining evil which the economists ascribe to this expedient was, that it attached to the number of votes a despotical authority, which can safely and usefully belong to *evidence* alone. "Under this system it is not evidence," they said, "which governs; it is opinion, or the will of a certain number of men actuated by the same opinion.

The mischief apt to result cannot be estimated; it is without bounds. Suppose, in fact, that the vote of the majority is dictated by private interests, and that *evidence* is on the side of the minority, is it not monstrous that the former should command, and that the form of the government should lend to bad design a title to triumph over evidence itself? This excess of disorder is nevertheless inevitable under so defective a plan of government; and the nation remains absolutely without protection against the scourges with which, under private interest set in opposition to public, it may be lacerated, especially if these private interests are the interests of men who, by their riches or otherwise, are in possession of power.

"We forget not," they said, "that the mischievous tendency of private interest would find a counterpoise in the *knowledge of the nation.* It is very true, that in a nation really enlightened, a nation that had from *evidence* the knowledge of its own true interests, the body of rulers could not abuse their authority. But why? because the evidence of the abuse would in that case annihilate the authority. But the idea of a nation governed by plurality of suffrage, and by evidence at the same time, involves an absurdity. Again, a nation sufficiently instructed to know all the links in the chain of social good and evil, would never sanction a form of government which places the common interest in opposition to the private interests of those to whom it is entrusted. Besides, it would be ridiculous to suppose a nation sufficiently instructed to have the wills of all united under the evidence of what is best in the social order, and to suppose its rulers at the very same time so ignorant as to be divided on those subjects, and reduced for a ground of decision to plurality of suffrage.

"So long, on the other hand, as a nation is not thus instructed, the people properly so called, sunk in ignorance and prejudices, see no farther than the nearest objects by which they are surrounded; each canton thinks the interest of the state is all summed up in the interest of that canton; each profession in the interest of that profession; the knowledge of relations and dependencies is absolutely wanting. Such men cannot ascend from effects to causes, much less enumerate the links in the chain of causes and effects. It becomes, therefore, morally impossible for them to act by principle and by rule. Ever credulous, and prone to prepossession, they must be gained in order to be persuaded; the same artifices must be practised upon them which are used to seduce them. The resolutions of men, the sport of momentary impressions, must have all the inconstancy of these impressions. Divided into rich and poor, the rich look upon the poor as made for them, and upon every power which they wish to possess as naturally their due. The poor, justly discontented with the treatment they receive, and mistaking the cause, are tempted to envy the condition of the rich, and to regard as injustice the inequality of the partition which is made between them. It is evidently, therefore, unsafe to choose the body of administration exclusively from either of these two classes. Nor would much be gained if one half were chosen from the one and the other from the other. If the separate portions continued to be governed by the prejudices and views of the classes to which they belonged, they would do nothing but contend; and there is only one way in which they could receive a motive to cease,—*if collusion would enable them to serve their own private interests by sacrificing the interests with which they were entrusted.*"

The economists come then to their grand conclusion with respect to the artificial or physical security of the social order. To the question, what is the best form of government, they answered, the government of a single individual, uniting in his own person the whole of the legislative and executive powers; in other words, absolute. "All men," they said, "would confess that the best form of government was that which was so perfectly conformable to the natural and essential order of societies, that no abuse could result from it; that form, in short, which renders it impossible to make gain out of misrule—which subjects him who governs to the absolute necessity of having no greater interest than that of governing well." This advantage would be found, they affirmed, in the government of an hereditary sovereign, and it would be found in no other.

The reason was, that in no other could the interests of governor and governed be rendered absolutely the same. As the hereditary sovereign is the hereditary proprietor of the sovereignty, the interest of the sovereignty is his interest. The interest of the sovereignty means the most perfect possible state of the governing authority; that is, the most perfect possible assurance of obedience to its command. But obedience to command can only arise out of the union of wills. And there can be no perfect assurance of the union of wills to obey but from one cause; the evidence that what is commanded is for the benefit of those who are to obey. The interest of the hereditary sovereign, therefore, and the interest of the community, is one and the same.

With regard to the famous idea of the *balance* of a constitution, that fancied arrangement of things in which the power and will of one part of the instruments of government finds a counterpoise in the power and will of another; this pretended counterpoise the economists treated as a perfect chimera, a mere imposition of the imagination, a sort of day-dream.

The nation, they said, is either instructed or not instructed. Let us examine the supposition of the balance in both cases. If it is instructed, or, in other words, possesses the evidence of the causes of good and evil in society, there is no balance of forces; there is only one force, because force follows will, and here wills are united. They carry the development of this idea to a great length, to which our limits will not permit us to follow them.

If the nation is not instructed, or, in other words, does not possess the evidence of the causes of good and evil in society, the establishment of counter-forces is impracticable. To ignorance there can be only one salutary counteracting force, and that is evidence. The effect of ignorance in the sovereign is dreaded; and to remove the dread, another man's ignorance is provided. This is what people call making counter-forces. It must be confessed that they are not of the very best sort of materials. How could it ever be imagined that confidence for any thing stable could be laid on any thing so unaccountable as the results of ignorance?

Let us adopt this chimera for a moment, and ask if it be possible to assure ourselves that each force will be the same to-morrow which it appears to be to-day. It is evidently impossible; nay, what each appears to-day may be a *false* appearance; for, resting only on opinion, detached from evidence, it rests on what can never be exactly known.

The idea of a balance is the idea of two powers, one tending by its own force in one direction, another urging it by an equal force in an opposite direction. The effect is rest. To balance the power of the sovereign acting in one direction, you provide another power acting in an opposite direction. If the powers are equal, they destroy one another, and there is no action. If they are unequal, there are not two powers, but only one power; for the greater swallows up the less.

The theory of a constitutional balance is founded on a metaphor, a contrivance of language; and moral forces are supposed to be subject to the laws of material forces. Material forces acting on a body in different directions,

make it assume a certain determinable duration between the two. But it has not been considered, that in physics the direction given does not depend upon the opinion of the things which act. In morals, on the other hand, the things which are depended upon for counteraction change their duration according to their opinion. A theory which supposes that to be uniform and constant which is known to be the reverse, is evidently absurd.

Suppose every thing which the theory needs to be supposed. Conceive an assembly, or assemblies, provided to counteract the sovereign, and so constituted, as to form the most perfect counteraction possible; that the sovereign can ordain nothing but with the consent of the assemblies, and the assemblies nothing but with the consent of the sovereign. In this case, it is not a government of one, but a government of many; each member of the assemblies shares in the sovereignty; they are so many partners, therefore, with a particular partner at their head. The question is, what are the interests of the partnership? Those of the nation or not? The interests of the partnership doubtless are, to make it as profitable to the members as possible; for it would be absurd to suppose them not governed by their private interests. Suppose, then, that there is originally a tendency to counteraction between the sovereign and the assemblies. It is very obvious that they will put an end to this counteraction, as far as they discover that the suspension of it is conducive to their private interests. This is a law of nature, and may be taken for granted. As far, then, as the serving of the private interests of the members is concerned, there is no balance of opposite forces; the forces combine instead of opposing, and so far the balance is lost. The loss of the balance to this extent may be a loss engrossing the whole of the protection to the common interest which it was expected to yield, or it may be a loss not extending so far. If it goes to the whole extent of that protection, there is to the purpose in question no balance at all. If it does not go to the whole extent, there will still be some balance, more or less. What then is the case? The case is, that the loss goes to the whole, and that the balance does not exist. The balance does not exist, as far as the private interests of those who share among them the governing powers are concerned. But it is only from the private interests of those who govern that the nation has any thing to fear; it is only against these interests that the balance is provided. As far, however, as these private interests are concerned, the balance does not exist. As far, therefore, as the balance is even *supposed* to be of any service, the balance is excluded by the law of nature. It follows as a corollary, that in a country where the people depend upon what is called *a balance* as the whole of their security for good government, they have no security at all.

Such is the analysis which the economists present of the causes of good and evil in human society, and of that order of things which best insures the presence of the one and the absence of the other. That part of their doctrine which alone is yet known to the mere English reader, their *Political Economy*, is introduced as only an auxiliary exposition. It is part of the development by which they endeavoured to prove the identity which they supposed between the interests of the sovereign and the interests of the people. But, as a very distinct account of this part of their system has been given by Dr Adam Smith and other writers, and as our object rather was the exhibition of those doctrines of the sect which nobody has yet presented to our countrymen in their own language, we shall content ourselves with only marking the place which their political economy held in their general system.

As the society has public expenses, it is necessary that it also have a public revenue. To reconcile the formation of a public revenue with the idea of social order, it ought to be formed, if possible, without infringing the property of individuals, for the sake of which the order of society itself is established. It ought, therefore, if possible, to be formed without diminishing the revenue of individuals. When the real origin of revenue, the source from which it all is drawn, is sufficiently understood, the mode of forming a revenue for the sovereign, without diminishing that of individuals, would be immediately apparent. *The source of all riches is the land; because the land alone, of all the sources of production, yields a produce greater than the cost of the production.* The surplus produce of the land, therefore, constitutes a fund, which is over and above the remuneration to the agents of production, and out of which the revenue of the sovereign may be taken, without diminishing the motive to production; that is, without retarding the natural progress of the state in wealth, population, and felicity.

To lay the foundation for this plan of a public revenue, it was necessary to prove that the land is the only source of production; and that manufactures and commerce, though they alter the form of things, never add any thing to the amount or value of production. In the development of these views, one of the most remarkable results at which the economists arrived was the necessity of perfect freedom to all the proceedings which lead to production; as giving to produce that form which is most agreeable to those who are to make use of it. Till the time of the economists, the necessity of holding those proceedings in chains, and binding them to the will of governments, was the universal doctrine of governments, and, to a great degree, of speculators themselves. The general principles of the economists respecting the *freedom* of property necessary to constitute the foundation of social order, led them to infer the evil of those abridgments of freedom; but they examined the inference in detail, and showed that the meddling officiousness of governments to compel industry to one thing, and exclude it from another, not only failed to effect any good purposes, but of necessity created obstructions of the greatest magnitude to production in general, and tended powerfully to keep down the wealth, population, and prosperity of the state. The light which they diffused on this subject, and which soon produced a grand effect on the minds of men, was a good, the magnitude of which is beyond calculation.

Another of their conclusions is, that the revenue of the sovereign, taken, as they said it ought to be, wholly from the net produce of the land, ought to be a fixed and unalterable proportion of that produce. The reason appeared to them conclusive. If the proportion was variable, and depended upon the will of the owners of the land, they might be induced to break upon the public revenue, and deprive the state of those benefits which the public revenue is necessary to produce. If it depended upon the sovereign, the property of the land might be detached from that of its produce; nobody would have a motive to become a proprietor in land, and all the advantages which depend on the existence of that property would be lost the production of subsistence would fail, and the community could not exist.

This proportion being once fixed, there is no longer any contrariety between the interest of the sovereign and the interest of any portion of his people; and the proprietors of land are as completely and securely exempt from contributing to the expense of the state, as any other class of the community. The sovereign derives no part of his revenue from the subject; and this deplorable source of the conflict of interests is wholly cut off. The proportion being settled for ever between the sovereign and the land-

owners, that alone is the property of the landowner which is the proportion remaining to him. The rest is, with regard to him, as if it did not exist. The sovereign they denominated, therefore, *co-proprietor* of the land; and between him and the landowner, commonly so called, a perfect community of interests is fixed. It is the interest of the sovereign that the produce of the land should increase, because, with every increase in the produce of the land, his revenue increases. It is also the interest of the landowner that the produce of the land should increase, because it is from the same cause that his revenue increases. See the article POLITICAL ECONOMY.

III. In the remarks which we have to offer on the doctrines of this sect, we must content ourselves with a few general strictures on one or two leading points.

The most important slips which the economists made in tracing the laws of the social order, are found in their deductions respecting the *tutelary authority*. Many steps, nevertheless, in that doctrine they have established. That the legislative and executive power are essentially the same, and cannot be separated except in *appearance*, they seem to us to have placed beyond the reach of dispute. That no security for good government can be found in an organization of counter-forces, or a *balance* in the constitution, they have proved in a manner equally satisfactory. But we think they have not proved that a security for good government can ever be found in the personal interests of a sovereign who unites in himself the whole of the legislative and executive power. And we think they have not proved that this security, if it cannot be found in the interests of such a sovereign, can be found in nothing else.

1. That the economists do not reason correctly from their own principles, when they regard the interests of the sovereign as an adequate security for good government, may be made apparent, we should hope, by an argument of a very few steps.

In a perfect state of the social order, they say that the interest of the sovereign would be the same with that of the community; and the evidence of this identity would be so clear to the sovereign, that the effect of it would be irresistible on his mind. But in a perfect state of the social order, they say also, that the interest of *every* man would consist in the most exact conformity to all the rules of that order, and that the evidence of this truth would be so apparent as to be sure of its effect. In the only state, therefore, in which the interest of the individual entrusted with the tutelary authority could be relied on as a security, the tutelary authority itself would not be required; for in a state in which every man would, of his own accord, do what is best, an authority to compel him to do so would be worse than useless.

The moment when you suppose a tutelary authority to be necessary, the moment at which you suppose there is any man in the community who can regard his private interest as consisting in any degree in what is hurtful to the community, how can you be sure that the depositary of the legislative and executive powers will not be that man? It can be easily shown that no man is acted upon by stronger forces to impel him in that direction.

In order to prove that the legislative power cannot be exercised by the community at large, the economists declare expressly, " that if we study the nature of each man in particular, we shall find in general that he would if possible have nothing but rights on his own side, nothing but obligations on the side of other men. The legislative power can be exercised with safety only by those who possess in perfection the evidence of the justice and necessity of the original and pervading laws of social order. It cannot, therefore, be exercised in safety by a body of men, among whom unequal rights exist, and must exist; and who at the same time are all separately desirous that the inequality should be in their favour."

Admit this—admit that all men in general desire to have nothing but rights on their own side, obligations on the side of other men; to have the inequality all in their own favour; to possess advantages, in short, over their fellows in the community; and it is surely absurd to talk of security in the interest of the sovereign.

It is a part of their doctrine, that he who is entrusted with the legislative power cannot be entrusted with the judicial power; because in that case the same party, both legislators and judges, would destroy law, by the exercise of arbitrary will. This is a direct admission, or rather an unlimited affirmation, that the interest of the sovereign is not a security such as good government requires. Again, it is said by the economists, " that under a government conformable to the principles of order, the positive laws would be of a justice and necessity *publicly evident;* and that in order to apply these laws, the judges would unite two sorts of knowledge, both of its meaning and of its reason; and, secondly, a knowledge of the facts which constitute the case in which they are required to decide." No men, according to them, are more urgently called upon, none can be more reasonably expected to be in full possession of the evidence of that interest which every man has in the preservation of the social order. Yet so far are the economists from saying that the interest of these men, and the evidence they could possess of that interest, would be a sufficient security for the right administration of their trust, that they declare them liable to the greatest malversations, and that the ultimate security would lie in the sovereign, who would check them. It is surely matter of wonder how the economists could fail to perceive, that the very same motives which they rejected as security for the right use of authority in the judges, they trusted to as complete security in the sovereign; though likely to operate on the judges with greater force than upon him.

2. We think it may also be made apparent, that the economists do not reason correctly from their own principles, when they conclude, that if security for good government cannot be found in the interests of one man entrusted with the whole of the legislative and executive powers, it can be found in nothing else.

They expressly state, that " the first, the real depositary and general guardian of the laws, is the nation itself, at the head of which is the sovereign. Accurately speaking, the deposit and guardianship of the laws *can* belong to those alone who are armed with the superiority of the physical force, to procure to that deposit its necessary superiority. This being evident, it is the nation as a body which naturally and necessarily is the depositary and guardian of its own laws; because there is in the nation no power comparable to that which results from the combination of its powers." Again,

In contending that the legislative and executive powers must always be exercised by the same hands, they affirm that those powers could only be exercised by those who had in their hands the superiority of the physical force. Observe, now, the legitimate conclusion:

The people alone have the physical force necessary to constitute them guardians of the laws. The same force is necessary for the makers and the executors of the laws. No body, therefore, but the people ever can, accurately speaking, have either the legislative or the executive powers. In a state of ignorance they may be led by fraud to lend their powers to their own destruction. But it is a part also of the doctrine of the economists, that in a state of knowledge, in which they may be easily placed,

Economy || Ecuador.

it is not possible they should make any but a good use of their power.

"A nation," they said, "governed according to the natural and essential order of society, has *necessarily* the perfect evidence and knowledge of it, and therefore sees with certainty that it enjoys its best possible situation. This perception, of necessity, unites all the wills and all the forces in the nation for the support of that order, and, by consequence, for the creation and preservation of all the institutions which are best adapted to that support." The people, therefore, may be safely trusted.

In a nation governed badly, governed not according to "the natural and essential order," but according to what the economists call the "*political* order," "it is always," they said, "one part of the nation which governs the rest; the weaker which governs the stronger. In this case, too, the power of him who commands consists in nothing but the powers united of those who obey him. And this union of their forces supposes, of necessity, the union of their wills; which can be founded only upon the persuasion that this obedience procures them their best possible condition. The powers of the nation in this vicious order are less at the disposal of the sovereign than at the disposal of those who hire to him their agency, and, by consequence, sell to him the means of procuring obedience from the nation; his situation is therefore at bottom a real dependence; his situation is precarious, uncertain, changeable; he is put in chains, which he dares not attempt to break." In every situation, therefore, it is the will of the people, either of the whole of the people united, or of a part of the people united against the rest, which is in reality both the legislative and the executive power. Estimate, therefore, as high as you please, exaggerate to any excess, the inconvenience of being governed by the people, you have that inconvenience still; you are bound to it by the inexorable law of nature; it is not within the range of possibility that you should escape from it.

Ecuador.

We have already seen that the economists declare that "every man wishes to have all the rights on his own side, all the duties on the side of other men; that every man likes inequality, in short, when the inequality is in his own power." From this they infer, that the community cannot safely govern; but from this it may with much more justness be retorted upon them, that nothing else can safely govern. The interest of the community, say the economists, is easily known; the evidence of it is within the reach of all descriptions of the people, and so cogent as to be irresistible. The union of wills, according to their doctrine, follows as a matter of course. Here, therefore, it should seem we have a much better security than can be found in the interest of any *individual*, sovereign or subordinate.

It is remarkable enough that the economists have wholly overlooked, in their criticism on the plans opposed to their own, *the representative system;* and yet it is pretty evident that it is by means of the representative system that the grand problem of government must finally be resolved. The speculations connected with this subject will, however, find a more fitting place under the article GOVERNMENT. (J.M—L.)

ECONOMY, POLITICAL. See POLITICAL ECONOMY.

ECSTACY. See EXTASY.

ECSTATICI (Ἐκστατικοί, from ἐξίστημι, *I am entranced*), in *Antiquity*, diviners who were cast into trances or ecstacies, in which they lay as if dead, but who, on recovering their senses, gave strange relations of what they had seen or heard.

ECTHESIS, in *Ecclesiastical History*, a confession of faith, in the form of an edict, published in 639 by the Emperor Heraclius, with a view to allay the troubles occasioned by the Eutychian heresy in the Eastern Church. He revoked it, however, on being informed that Pope Severinus had condemned it as favouring the Monothelites; declaring at the same time that Sergius, patriarch of Constantinople, was its author.

Name, situation, and boundaries.

ECUADOR, an independent state of South America, lying under the equator, from which it takes its name. It corresponds, with a trifling difference, to the old Spanish province or intendancy of Quito; but formed anciently the northern portion of the empire of the Incas of Peru, and latterly the south-western province of the now dissolved republic of Columbia. It is situate between S. Lat. 6. and N. Lat. 2., and W. Long. from Greenwich 70. and 82.,—being about 830 miles in length from E. to W., and 560 in breadth from N. to S.,—and only contains an area of about 320,000 English square miles. It is bounded on the S. by the state of Peru, on the N. by New Granada, on the E. by Brazil, and on the W. by the Pacific Ocean; but the boundaries of the eastern portion of the state are not yet very well defined.

Physical formation.

The western portion of the state, to the extent of about a third of its area, is covered with mountains. These consist principally of a cross section of the Andes, about 7° in length, forming at the northern and southern boundaries respectively the two large mountain-knots of Loja or Loxa, and Pastos. Between these knots the range of the Andes forms a single mass, about 300 miles in length and from 70 to 80 miles in breadth, rising with a steep acclivity at the distance of about 70 to 90 miles from the shores of the Pacific Ocean to a mean elevation of about 9000 feet, and forming on its summit a long plateau or table-land, bordered on each side by parallel ranges of mountains, which again rise several thousand feet higher, and have their peaks covered with perpetual snow. The highest, or those on the E. and W. sides of these ranges, are about 50 miles apart, while the lower and interior ranges occupy a breadth of several miles on each side, leaving between them a narrow belt of flat ground—from 15 to 24 miles in width, and 300 miles in length from N. to S.—divided into three parts by two cross ridges. The southmost portion forms the valley of Cuença, which has an elevation of about 7800 feet; the northmost is the celebrated plain of Quito, which has a mean elevation of about 9600 feet; and between them is the valley of Alausi and Ambato, with a mean elevation of 8000 feet. The valley of Cuença is connected with the middle valley by the pass of Assuay, the crest of which rises to the great elevation of 15,520 feet; but the ridge between Allausi and Quito, called the *Alto de Chisinche*, rises only about 500 feet above the contiguous plains on the N., and is of inconsiderable width. Among the lofty summits that border these valleys, the following table gives the names of the principal, with their elevations in feet above the level of the sea:—

	Feet.		Feet.
Chimborazo	21,424	Chumbal	16,824
Cayambe-Urcu	19,534	Carguairazo	16,663
Antisana	19,137	Cotocache	16,448
Cotopaxi	18,875	Tunguragua	15,960
Iliniza	17,376	Pichincha	15,936
Sangay	16,827		

With the exception of Chimborazo, all these are active, or only recently quiescent volcanoes; and the surrounding districts are subject to frequent earthquakes, some of which have been terribly destructive.

Between the Andes and the sea the country is covered with mountains, which, however, do not seem to form continuous ridges. The shores themselves are high, rising along the Pacific with a bold and broken line of gulfs, bays,

Ecuador. and headlands, except at the S.W., where the Gulf of Guayaquil, 70 miles wide, terminates inland, with an alluvial valley, or long plain, several miles in breadth, and so low as to be always flooded in the rainy season. In the bosom of the gulf lies the island of *Puna*, with an area of more than 200 square miles, but inhabited only by a few fishermen.

To the eastward the Andes sink abruptly into the great plain which extends eastward to the Atlantic Ocean along the river of the Amazons and its mighty tributaries, some of which have their sources among the mountains of Ecuador. In this direction flow the waters of the valleys of Cuença and Alausi, and Hambato, while those of Quito find their way to the Pacific through the rivers of Patias and Esmeraldas. So far as within this state, the great plain is partly wooded and partly a savannah interspersed with many lagunes and stagnant pools, and intersected by innumerable streams flowing from the Andes.

Geology. Granite seems to form the basis of the whole range of the Andes, but it rarely appears on the surface. Gneiss is sometimes found in connection with the granite, but mica-schist is by far the commonest of the crystalline rocks. Quartz is likewise very abundant, and vast tracts of red sandstone with gypseous and saliferous marls occur near Quito. Porphyry and greenstone abound all over the range, and great masses of trachyte, from 14,000 to 18,000 feet thick, are visible on Chimborazo and Pichincha. Basalt, of columnar structure, inclosing olivine, and overlaid with thick beds of clay, is found on the table-land of Quito. Immense quantities of lava, tufa, obsidian, and other volcanic products, are likewise found, particularly along the western face of the Andes.

Climate. Although this state lies under the equator, the great elevation of the mountain mass of the Andes renders the climate, in the elevated districts, mild and temperate. In the valley of Quito there prevails an everlasting spring, so equal in its temperature that vegetation never ceases; and the city has acquired the title of *Sempre verde* (ever-green), and *Eterna primavera* (everlasting spring). The change of seasons is scarcely perceptible, while the mean temperature of the day, all the year round, varies only from 60° to 67°, and that of night from 48° to 52° Fahr. The season between September and May is called winter, and the rest of the year summer; but the winter is only distinguishable by a somewhat greater quantity of rain, and the summer by a greater number of fine days. All the year round, however, scarcely a day passes without rain. In the mornings and evenings the sky is generally clear and serene, but in the afternoon it is generally overcast with dark clouds, which pour down torrents of rain, often accompanied with awful storms of thunder. Sometimes, however, the rain continues all night, and occasionally three or four days together. Wind blows continually along the valley, either from the north or from the south, but never with great violence. In the low country on the coasts the climate is very different. At Guayaquil the temperature is generally between 98° and 104°, and people complain of cold when it falls to 84° or 86°. In the other valleys along the coast the mean temperature of the year varies between 78° and 82°; but from December till April the heat rises to 95°, and during these months rain falls with little interruption, frequently accompanied with violent tempests. The floods at that season are so great, that in the valley of Guayaquil the country becomes one sheet of water even to the base of the Andes, to which the people betake themselves for refuge, with their herds and flocks. Fevers, diarrhœas, dysentery, vomiting, and spasms, then prevail, and the mortality is often very great. On the acclivity of the Andes, at the elevation of 3000 to 5000 feet, a soft spring temperature prevails, never varying more than 7° or 8°, and the mean temperature of the year being from 68° to 70°. The great eastern plain has a hot climate, the mean temperature being probably from 75° to 85°. The heat sometimes rises to 95°; but every day, early in the afternoon, a wind, generally accompanied with rain, begins to blow from the eastward with great force, and continues till sunset.

Vegetable productions. In the low countries that flank the base of the Andes the banana, cycas, plantain, cacao, jatropha which produces cassava and manioc, the cotton tree, indigo, coffee, and the sugar-cane abound; beneath the elevation of 4000 feet, the plants chiefly cultivated for food are the sweet potato, mandioc, yam, and banana, with rice, maize, and some legumes; but above 3100 feet most of these become rare, and thrive only in particular situations. The sugar-cane, however, has been grown so far up as 7500 feet. In some of the valleys are extensive plantations of sugar-cane, cotton, tobacco, and cocoa. The valley of Guayaquil is particularly fertile; the soil is alluvial, and there are few spots even between the tropics which can vie with it in richness and variety of vegetation. It is covered with groves of every kind of tropical fruits, either wild or cultivated, as the pine-apple, pomegranate, shaddock, orange, lime, lemon, peach, apricot, cherimoyer, pulta, granadilla, tuna, and pacay. In the same region are found the olive, pepper plant, tomatas, and sweet potatoes, gum copal, copaiba balsam, carana, dragon's blood, sarsaparilla, and vanilla. To these succeed, in the humid and shaded clefts on the slopes of the mountains, tree ferns and cinchona or Peruvian bark, the finest kind of which is obtained about 8 to 12 miles S. of Loja among the mountains of Uritusinga, Villanaco, and Rumusitana, where the trees that yield it grow in a soil resting on mica-slate and gneiss, at the moderate elevation of 5756 to 7673 feet above the level of the sea. Between the elevations of 6000 to 9000 feet is the region best suited for the European cereals. Wheat will not form the ear lower than at 4500 feet, or ripen higher than at 10,000 feet; but barley and rye grow at an elevation 2500 feet still higher. To these may be added the guinoa, a most useful production for domestic purposes. In this region also, and a little above it, grow the potato and its congeners, all of which are extensively used as food; the chick pea, broad bean, cabbage, and other European vegetables, are likewise abundant. Within the cereal limits are found the oak, elm, ash, and beech, which never descend lower than 5500 feet, and are seldom found higher than 9200 feet above the level of the sea. Higher up, the larger forest trees, except the pine, begin to disappear; and on the mountains of Quito the escallonia mark the highest limit of trees at an elevation of 11,600 feet. The bejarias, the highest of shrubs, terminate at 13,400 feet, above which, in rich and beauteous verdure, rises the zone of the grasses. Above these, among the trachyte rocks, only lichens, lecideas, and the brightly coloured dust-like lepraria are met with; and to these succeed the region of perpetual snow.

Animals. In some parts of the low country the air swarms with musquitoes and other flies still more tormenting, while the ground teems with snakes, centipedes, and other reptiles. The banks of the great rivers are crowded with caimans or alligators. Bats are exceedingly numerous and of great size; the forests of the warmer regions abound with armadillos, monkeys, and cavys; and everywhere are found the jaguar, the puma, the ounce, the ocelot, and several varieties of the wild cat. The pecari and deer are likewise common, as well as that singular animal the ant-eater. The characteristic animals of the Andes are the llama, the guanaco, the vicuña, and the paco or alpaca, some of which are trained as beasts of burden, while others, particularly the vicuñas, run wild among the mountains, where they are hunted by the Indians. Sheep and cattle are reared in great numbers, especially the former, in the valleys of the Andes, and on the declivities of the mountains. Horses, asses, and mules, are reared in sufficient numbers to be articles of export. The chief of the birds is the condor, which is found all along the Andes southward as far as the

Ecuador.

Strait of Magellan, but nowhere to the north of the equator. The turkey, vulture, and gallinago, are frequently met with, together with many kinds of smaller birds. In some districts, particularly along the coasts, considerable quantities of bees-wax are collected; and higher up there are spots in which the cochineal insect is reared. Along the rivers of the great plain turtles are numerous; and their fat, called *manteca* butter, forms a considerable article of trade. Fishing is carried on to some extent along the coasts, and a good deal of salt-fish is prepared. A murex is also found which yields a juice used in dyeing purple.

Mineral productions.

Ecuador is less rich in minerals, especially in the precious metals, than any other of the South American states. There are indeed several mines of gold and silver, but the yearly produce is inconsiderable. In some places are found lead and quicksilver, but the latter is found, as usual, in combination with sulphur, in the form of cinnabar. Near Azogue, 15 miles N.E. by E. of Cuença, the ore is found in an immensely thick bed of quartzose sandstone, containing fossil wood and asphalt. Sulphur is prepared in considerable quantities; gold has been washed from the sands of some of the rivers; and salt is obtained from sea-water along the coasts.

Population.

The settled population is composed of Spanish creoles of pure descent, meztisos, mulattoes, and negroes, the greater part of them being agriculturists, graziers, and growers of cocoa. These form about a half of the population. The other half are native Indians, of whom those that live among the mountains are mostly agriculturists, cultivating their lands with much care, and making for themselves coarse stuffs of wool and cotton. The Indians who inhabit the eastern plains are in a much lower degree of civilization. They cultivate only small patches of ground, and apply themselves chiefly to hunting and fishing. Three-fourths of the population dwell in the western or mountainous part of the state; and the total number is now estimated at about 800,000.

Manufactures.

The manufactures are unimportant, consisting chiefly of coarse woollen and cotton cloths and other necessary articles. The foreign trade is almost confined to Guayaquil, and is so trifling as scarcely to deserve notice.

Political condition.

Till 1812 Ecuador remained a portion of the Spanish empire of the Indies. It then threw off the yoke of Spain, and in 1821 became a part of the newly constituted republic of Columbia. This union, however, lasted only till 1831, when Ecuador became an independent state. It has gone through several revolutions; and by the last (1852–3) the democratic party has gained the ascendency, and shown a tendency to adopt the United States of North America as their political model. The state has in consequence received a new and more liberal constitution; the Jesuits have been expelled; and laws have been made for the abolition of slavery. The government is vested in a president, with a vice-president and two chambers, all elective; but the constitution is still notably complicated by what has always been its principal characteristic, a predominating mixture of military despotism, the president being always the master of the state. More, perhaps, than any other country of South America, Ecuador has been slow in the development of her resources and national industry. Frequent revolutions have paralysed its trade, and prevented the regulation of its finances. No interest has been paid on its public debt since 1826. It is emphatically the country of natural convulsions and political revolutions.

For adminstrative purposes the state is divided into the three departments of *Ecuador*, *Guayaquil*, and *Assuay;* and these are subdivided into the seven provinces of *Quito*, *Riobamba*, *Ibarra*, *Guayaquil*, *Babahoyo*, *Cuença*, *Loja*, or *Loxa* (Loh-ha), and *Jaen de Bracamor.* The state likewise claims the sovereignty of the *Islas de los Galapagos*, or islands of land turtles, lying under the equator at a distance of 700 to 900 miles from the mainland. The chief towns are, *Quito*, with from 50,000 to 80,000 inhabitants; *Guayaquil*, 25,000; *Cuença*, 20,000; *Riobamba*, 15,000; *Loja*, *Babahoyo*, and *Ibarra*, about 10,000 each. Quito is beautifully situated in the elevated plain to which it gives its name; and Guayaquil on the banks of a navigable river, opening into the spacious bay to which it gives its name.

Edda.

EDDA, a system of the ancient Icelandic or Runic mythology, containing many curious particulars of the theology, philosophy, and manners of the northern nations of Europe; or of the Scandinavians who had migrated from Asia, and from whom our Saxon ancestors were descended. Mallet was of opinion that it was originally compiled soon after the Pagan religion was abolished, as a course of poetical lectures, for the use of such young Icelanders as devoted themselves to the profession of scald or poet. It consists of two principal parts; the first containing a brief system of mythology, properly called the *Edda;* and the second being a kind of art of poetry, and called *Scalda* or *poetics.* The most ancient Edda was compiled by Soemund Sigfusson, surnamed the Learned, who was born in Iceland about 1057. This was abridged, and rendered more easy and intelligible, about 120 years afterwards, by Snorro Sturleson, who was supreme judge of Iceland from 1215 to 1222; and it was published in the form of a dialogue. The latter added also the second part in the form of a dialogue, which is a detail of different events connected with the heathen divinities. The only three pieces which are known to remain of the more ancient Edda of Soemund are the Volupsa, the Havamaal, and the Runic chapter. The Volupsa, or prophecy of Vola, or Fola, appears to be the text on which the Edda is the comment. It contains, in two or three hundred lines, the whole system of mythology disclosed in the Edda; and may be compared to the Sibylline verses, on account of its laconic yet bold style, and its imagery and obscurity. It is professedly a revelation of the decrees of the father of nature, and the actions and operations of the gods. It describes the chaos, the formation of the world with its various inhabitants, the functions of the gods, their most signal adventures, their quarrels with Loke their great adversary, and the vengeance that ensued; and it concludes with a long description of the final state of the universe, its dissolution and conflagration, the battle of the inferior deities and the evil beings, the renovation of the world, the happy lot of the good, and the punishment of the wicked. The Havamaal, or Sublime Discourse, is attributed to the god Odin, or Woden, who is supposed to have given these precepts of wisdom to mankind. It is comprised in about 120 stanzas, and resembles the book of Proverbs. Mallet has given several extracts from this treatise in his Northern Antiquities. The Runic chapter contains a short system of ancient magic, especially of the enchantments wrought by the operation of Runic characters, of which a specimen is also given. A manuscript copy of the Edda of Snorro is preserved in the library of the university of Upsal: the first part of it was published with a Swedish and Latin version by M. Goranson. The Latin version is printed as a supplement to Mallet's Northern Antiquities. The first edition of the Edda was published by Resenius, professor at Copenhagen, in the year 1665, in a large quarto volume, containing the text of the Edda, a Latin translation by an Icelandic priest, a Danish version, and various readings from different manuscripts. Mallet has also given an English translation of the first part, accompanied with remarks; from which we learn, that the Edda teaches the doctrine of the Supreme, called the Universal Father, and Odin, who lives for ever, governs all his kingdom, and directs the great things as well as the small; who formed the heaven, earth, and air; who made man, and gave him a spirit or soul, which will live after the body shall have mouldered away · then all the just shall dwell with him in a

place called Gimle or Vingolf, the palace of friendship; but wicked men shall go to Hela, or death, and thence to Niflheim, or the abode of the wicked, which is below in the ninth world. It inculcates also the belief of several inferior gods and goddesses, the chief of whom is Friga or Frea, that is, *lady*, meaning thereby the earth, who was the spouse of Odin or the Supreme God; and hence we may infer that, according to the opinion of these ancient philosophers, this Odin was the active principle or soul of the world, which, uniting itself with matter, had thereby put it in a condition to produce the intelligences or inferior gods, and men, with all other creatures. The Edda likewise teaches the existence of an evil being called Loke, the calumniator of the gods, and the artificer of fraud, who surpasses all other beings in cunning and perfidy. It teaches the creation of all things out of an abyss or chaos; the final destruction of the world by fire; the absorption of the inferior divinities, both good and bad, into the bosom of the grand divinity, from whom all things proceeded as emanations of his essence, and who will survive all things; and, lastly, the renovation of the earth in an improved state.

EDEMATOUS, or Edematose, (οἴδημα, *a swelling tumour*,) filled with a serous humour; dropsical.

EDEN, the country and garden in which Adam and Eve were placed by God himself. The term denotes pleasure or delight. The garden is also called Paradise—a term of Persic original, signifying a garden. In regard to its locality, it is generally agreed that we ought to look for it in the south of Armenia. See Paradise.

Eden, a river of England. See Cumberland.

EDENDERRY, a market-town of King's County, Ireland, at the N.E. extremity of the bog of Allen, 33 miles W. of Dublin. It is a neat, clean, and comparatively prosperous town; and has a considerable trade in corn. Pop. (1851) 1804, besides 1023 in the Union workhouse.

EDENTATA, Cuvier's sixth order of mammiferous animals, characterized by the absence of fore-teeth. See Mammalia.

EDER, a town of Hindustan, province of Guzerat, and the principal place of the rajpoot state of the same name. The town contains 1200 houses, with a population of about 10,000. The petty state of Eder was founded in the early part of the eighteenth century by Anund Sing and Raee Sing, sons of the celebrated Ajeet Sing, rajah of Joudpore; the territory having been assigned to them by their elder brother the viceroy of Guzerat. The annual revenue is estimated at about L.24,000; of which L.3300 is paid as tribute to the Guicowar. The political connection of the British government with this state commenced in 1820 in the arrangement with the Guicowar, under which that prince stipulated to withdraw his troops from the district, and the British government engaged to collect the Guicowar's dues free of all deduction. Upon the election in 1841 of Tukht Sing, the rajah of Ahmednuggur, to the throne of Joudpore, his possessions in Guzerat were claimed by the ruler of Eder as the feudal superior; and the claim having been recognised by the British government, the possessions of Ahmednuggur thenceforward merged into those of Eder. The town of Eder is in Lat. 23. 50., Long. 73. 3. (E. T.)

EDESSA, a later name of the ancient Ægæ, the capital of Macedonia, was situated in the very centre of that kingdom, at the head of a defile commanding the approaches from the sea-coast to the interior of the country. Its lofty and commanding position, and the magnificent surrounding scenery, combined with its historical interest, caused it to be regarded by the Macedonians with peculiar veneration, more especially as from it sprang the dynasty of their kings. Even after the seat of government was removed to the more accessible Pella, Edessa continued to be the burial-place of the royal family. It was at this town that Philip fell by the hand of his murderer Pausanias; and it was originally intended that the remains of the great Alexander should here repose beside the ashes of his ancestors, though the scheming Ptolemy contrived that they should be interred at Memphis. When Pyrrhus and his Epirotes overran the country, they opened the tombs of the Macedonian kings, in the vain hope of bringing to light some buried treasures of great value. The site of Edessa is occupied by the modern Vodhena, where a few unimportant remains of the ancient town may still be seen.

Edessa, or Callirrhoe, a city in the north of Mesopotamia, in the province of Osrhoëne, on the banks of the small river Scirtus, a tributary of the Euphrates. The time and manner of the foundation of this city are very variously given by different authors: by some writers its origin is even referred to Nimrod; and though this account may be very safely rejected, yet the extreme antiquity of the place is undeniable. Its very position is also variously given by the ancient geographers. Strabo, for instance, confounding it with Hierapolis, places it in Syria, while Pliny makes mention of it as being in Arabia.

It was not till the Christian era that Edessa began to play a part in history. In the wars between the Eastern empire and the Persians, and in the early history of the church, the name of Edessa very frequently occurs. One of the most important theological schools of the primitive church had its seat in this city, and distinguished itself by the zeal with which it maintained the Nestorian heresy. This zeal ultimately proved the ruin of the school, whose professors were banished from Edessa by the orthodox bishop Martyrus, while the building in which they had taught was pulled down by order of the emperor Zeno, towards the end of the fifth century.

In the wars with the Persians, Edessa frequently suffered great damage; and though this was immediately repaired, yet the destructive inundations of the Scirtus on more than one occasion threatened to endanger the very existence of the town. In 718 Edessa was nearly destroyed by an earthquake; and in 1184 it fell into the hands of the Saracens, under whose rule its prosperity rapidly declined. Under the name of Orfah, Edessa has recovered to a certain extent its ancient greatness, as it stands on the great route between Kurdistan and Aleppo, and has consequently become a place of very considerable commercial importance.

EDFU, a village of Upper Egypt, remarkable for its two temples. See Architecture, vol. iii., p. 458; and Egypt.

EDGEWARE, a village of Middlesex, 10 miles W.N.W. from London. It was formerly noted for the magnificent palace of the Duke of Chandos; the site of which is now occupied by a villa constructed out of the materials of the former palace.

EDGEWORTH, Richard Lovell, a distinguished essayist, was born at Bath in 1744. He received his education at Oxford, and in his after-life devoted himself to literary pursuits. His name is honourably known from his efforts in the cause of education and agricultural science. He is also said to have been the originator of several ingenious inventions, and some have claimed for him the invention of the telegraph. Most of his works were written in conjunction with his daughter; and she has also published a continuation of his "Memoirs." Mr Edgeworth was a member of the Irish House of Commons about 1794. He was four times married; and died at Edgeworth's Town in June 1817.

Edgeworth, *Maria*, an eminent English novelist, and daughter of the preceding by his first wife, was born in Berkshire, Jan. 1, 1767. She removed to Ireland when her father succeeded to the family estate in 1782, and there she spent the greater part of her life. Her literary career began with the publication of *Castle Rackrent* in 1801; and this was soon followed by the *Moral Tales*, *Belinda*, *Leonora*, *Tales of Fashionable Life*, *Patronage*, *Harring-*

Edinburgh. *ton and Ormond*, and other works. It was the humour, tenderness, and tact displayed in her admirable delineations of Irish character that first suggested to Sir Walter Scott the design afterwards carried into effect in the Waverley Novels. Parallel with this series of works of fiction, Miss Edgeworth directed her literary efforts to the cause of education. Her essays on *Practical Education* were published so early as 1798, and her latest work was the child's story of *Orlandino*, which appeared in 1834. The *Parent's Assistant*, and numerous other educational works, fill up the intervening period. Among the works to which her father's name is attached along with her own, the most famous is the *Essay on Irish Bulls*, published in 1803. The latter part of Miss Edgeworth's life was spent in peaceful retirement at Edgeworth's Town, whence, with the exception of a trip to the Continent and a short residence at Clifton, she had scarcely ever removed, and where she died in May 1849.

Edhiling || Edinburgh.

EDHILING, Edhilingus, an ancient appellation of the nobility among the Anglo-Saxons. It is sometimes written *atheling* or *ætheling;* which appellation properly pertained to the presumptive heir of the crown.

EDICT (*edicere, to publish*), that which is uttered or proclaimed by authority as a rule of action; as an order or ordinance issued by a prince to his subjects, either as a temporary regulation or as a permanent law. Strictly speaking, edicts cannot exist in Britain, since the power of enacting laws is lodged not in the sovereign but in the parliament.

EDINBURGH.

Situation.

Edinburgh, the capital of Scotland, and chief town of Mid-Lothian, or Edinburghshire, is situated within two miles of the south shore of the Firth of Forth, at the distance of about 392 miles north from London, in N. Lat. 55. 57. 20.; and W. Long. 3. 10. 30. The situation of this ancient city is pre-eminently romantic. It occupies a congeries of hills and elevated grounds, rising gradually from the shore of the Forth, and attaining in some parts to a considerable height above the level of the sea. The central elevation, which has been aptly compared to a wedge lying flat upon the ground, is terminated at its highest or western extremity by a mass of rock, seven acres in superficies at top, and about 250 feet above the surrounding country; on which stands Edinburgh Castle, the nucleus of the city. From the castle, along the slope towards the east, and for a mile in length, the Old Town was built, with a spacious street in the centre, and narrow alleys or closes diverging down the north and the south sides of the ridge. In later times the city, by means of bridges, was extended to the grounds on the south and north.

Origin and name.

The etymology of the name Edinburgh has been supposed to be found in the history of its origin. It is said that subsequently to the year 449, or the era of Anglo-Saxon dominion in Lothian, the castle became the occasional residence of the chiefs of the Northumbrian dynasty; and from Edwin, the potent king of the territory, the appellation *Edwin's burgh* was introduced and afterwards retained. At a period coeval with or preceding the era of Edwin, the name applied to the fort was *Mai-din* in British, or *Magh-dun* in Gaelic, which may either signify the fortified mount in the plain, or the good fort; but when the English language came into use, the *Maiden* Castle gave occasion to fanciful etymologists to connect the title it obtains in old writings—that of *Castrum Puellarum*, the Castle of Maidens—with the fable that it had been the residence of the daughters of the British kings. The origin of Edinburgh can now with tolerable accuracy be traced to the beginning of the seventh century, or the era of Edwin, from which period it gradually though slowly increased in size. In the year 856 it is described as a considerable village; and, with the castle, it was often the object of contest in the wars which took place between its Anglo-Saxon possessors and the natives of Scotland. From the period of the cession of Lothian to the Scots in 1020, the castle continued to be the frequent residence of their monarchs; and here the widowed consort of Malcolm Ceanmore, the pious and worthy Margaret, died in the year 1093. In the reign of David I. the castle continued a royal residence, and the town increased so much as to be considered one of the four chief burghs in the kingdom. Soon after his accession, the munificent David founded the Abbey of Holyrood on the plain at the eastern extremity of the rising ground on which Edinburgh was built. On the canons of this abbey he conferred the privilege of building a suburb westward from their church, along the ridge, in order to meet the burgh; and the new town thus reared by the monks received the name of *Vicus Canonicorum*, or popularly *Canongate*, which title the eastern part of the old city still retains. For a considerable period after the reign of David, the houses of Edinburgh were all thatched with straw; but the town nevertheless rose into importance, and in the twelfth century it was constituted a royal burgh by William I., surnamed the Lion.

The death of Alexander, king of Scotland, proved disastrous to Edinburgh. In June 1291 the town and castle were surrendered to Edward I.; but in 1313 they were recovered by assault, under the conduct of Randolph earl of Moray, and the castle was destroyed. The English again took and repaired the castle under Edward III., who resided there and placed a strong garrison in it. In 1337 the castle, still in the custody of the English, was besieged by Sir Andrew Moray, the guardian of Scotland, though without success; and it was only by an ingenious stratagem, employed by Sir William Douglas, in 1361, that the fortress was secured by the Scottish patriots.

From the era of the murder of James I. at Perth, in 1436–37, the origin of Edinburgh as a national capital may be dated. Neither Perth nor Scone, Stirling nor Dunfermline, being able to secure royalty against the designs of the nobility, Edinburgh and its castle were selected as the only places of safety for the royal household and the functionaries of government. The infant sovereign was crowned in the chapel of Holyrood, in which sat the first parliament of his reign. James II. was particularly attached to Edinburgh, and bestowed on it a variety of grants as to the holding of fairs and markets, the levying of customs, and also rights to property. Besides, in 1450, he sanctioned the erection of walls and bulwarks for its defence. Edinburgh was the seat of the court and regular parliament throughout the turbulent reign of James III., who conferred additional immunities upon the city, and granted to the magistrates, town-council, and community, the office of heritable sheriff of the burgh. On account of the loyalty of tne people in assisting him against Edward IV. he moreover granted the inhabitants a banner, with power to display the same in defence of their king, their country, and their own rights. This flag, which is still esteemed a sort of palladium of the city, is called from its colour the *Blue Blanket*, and remains in the custody of the Convener of the Trades. In 1497, Edinburgh was visited by a loathsome distemper imported from abroad, and the king by a proclamation ordered the magistracy to put out of the town all infected persons, who, in order to free the city, were transported by boats to the island of Inchkeith in the Firth of Forth, which thus served as a lazar-house for the time. James III., in his latter years, made Edinburgh castle the repository of his treasure, valuable effects, and ordnance. In

1488, when this prince was murdered near Stirling, the whole fell into the hands of his rebellious subjects.

The first parliament of James IV. was held at Edinburgh; and in 1503, on the marriage of this prince with Margaret, the eldest daughter of Henry VII. of England, the capital was the scene of a gorgeous pageant, which is fully recorded by the historians of the time. In 1508 the king empowered the town to feu the grounds of the Boroughmuir on the south; but the citizens were no sooner in possession of this grant, than they set about clearing the ground of its wood, and so many trees were cut down that they could not be disposed of; wherefore the magistrates enacted, that whosoever should buy as many trees as would form a new front to a house, might extend the same seven feet farther into the street. The consequence of this was, that Edinburgh was in a short time filled with houses of wood, and the principal street was reduced fourteen feet in breadth. The year 1513 was the epoch of a dreadful plague; and also of that great national calamity, the defeat at Flodden. With James perished the magistrates and many of the burgesses; the privy-council removed to Stirling for safety; the Cowgate and Grassmarket, at that time southern suburbs of the town, were inclosed with a wall; and at the same time the corporation of the burgh raised the civic military corps called the town-guard, which was not finally disbanded till the year 1817.

Throughout the minority of James V. the capital was the constant scene of tumults. One especially, between the Hamiltons or Arran's party and the Douglases or party of Angus, is known in history by the name of *Clear the Causeway.* May 1532 is the era of the greatest event in the annals of the Scottish metropolis. This was the establishment of the College of Justice, or series of supreme courts and their functionaries. The city now became a place of resort from all parts of the kingdom, and the magistrates for the first time had the High Street repaired and paved, and gave orders to the citizens to light it. In 1538 the town was the scene of rejoicings, on the entrance of James with his wife Mary of Guise.

In 1544, on the refusal of the regency to ally the young Queen Mary to the son of Henry VIII., an English fleet and army were sent to ravage Scotland; and in prosecution of this object the earl of Hertford landed with a force near Leith, and set fire to the city in several places. In 1548 Edinburgh was garrisoned by French troops under D'Essé, who prevented the English from committing any further serious damage.

Disturbances consequent on the change of religion in Scotland broke out in 1556, at which time a concourse of people assembled to protect John Knox from the violence of the ecclesiastical judicatory. During the struggle which ensued in effecting the Reformation, Edinburgh formed the chief position of the Reformers, as Leith was that of the French and Catholic party. By the assistance of a Protestant army sent by Queen Elizabeth the Reformers were finally triumphant, and the first assembly of the Reformed kirk met at Edinburgh on the 15th of January 1560.

A new object of excitement soon appeared in the person of Mary, the young queen of Scots, who on the 9th of August 1561 arrived at Leith from France. On the 1st of September she made her public entry into the city. Darnley was proclaimed king at the market-cross in July 1565, and next morning was married to the queen in the chapel of Holyrood. In June following the queen was delivered of a son, afterwards James VI.; and in February 1567 Darnley was blown up by gunpowder in a house at the Kirk of the Field, on the site of which the university now stands. Mary's marriage with Bothwell occasioned fresh disturbances in Edinburgh; and during the period of the irregular warfare which ensued between the king's and queen's parties the city suffered very severely. At length the young king himself entered upon public life, and on the 17th of October 1579 arrived in the metropolis with a cavalcade of 2000 horse, and held his first parliament in person. In the year following the Earl of Morton was beheaded in Edinburgh, by an instrument called the *Maiden,* which it has been said he had himself introduced, and which is now preserved in the Museum of the Society of Antiquaries. The character of the city was about this period greatly improved by the erection of the college, which was commenced in 1581, and to which the first professor was appointed in 1583. The infant institution was warmly patronized by King James, who, on the occasion of a temporary visit which he made to Scotland in 1617, desired that it should thenceforth be called King James' College. In 1585-86 the city was visited by the plague, and suffered severely from that disease. In 1591 the inhabitants were alarmed by an attempt of Francis Stewart Earl of Bothwell to seize upon the person of the king in Holyrood Palace. The attempt, however, was defeated by the promptitude and vigour of the citizens. Bothwell himself escaped, but eight of his followers were taken and put to death on the following day. In 1596 the clergy and citizens united in tumultuary resistance to an attempt made by the king to control the language of the pulpit. Unable to subdue or restrain the insurrectionary spirit which he had excited, James withdrew from the town, and ordered all the public courts to be removed from it. A reconciliation, however, soon afterwards took place, and the offended monarch returned peaceably to his capital. In 1599 the first regular dramatic actors appeared in Edinburgh. They came from England, and there is some reason to suppose that the immortal Shakspeare was amongst the number.

Three years later the regal dignity of Scotland became extinct, or rather merged in that of England. On the 24th of March 1603 James was called to the throne of the sister kingdom. Two days before his departure he addressed the citizens in St Giles' Church; promising them a continuation of his countenance, and expressing the regret which he felt at leaving them. Among the marks of royal favour with which James visited Scotland after his accession to the throne of England, was his empowering the magistrates of Edinburgh, in 1609, to have a sword of state carried before them, and to wear gowns. This, it is believed, was the earliest appearance of magisterial robes in Scotland. In 1617 James paid a long-promised visit to his native country. He entered Edinburgh by the West Port, and was conducted through the city with great pomp, and every demonstration of rejoicing. On the 28th of June he convened his twenty-second parliament at Edinburgh. In this assembly there were several remarkable acts passed, including one for the restitution of archbishops, bishops, and chapters. Four years after this, namely, in 1621, an act of the estates and town-council was passed for coping houses with lead, slates, or tiles, instead of thatch, which had hitherto been the covering commonly employed. In the same year water was introduced by pipes into the city; and three new bells were imported from Campvere in Zealand, two for St Giles' Church, and one for the Netherbow Port. The casting of bells for churches, however, is much more ancient in Scotland. On one of four fine bells in the ancient cathedral of Kirkwall in Orkney there is an inscription—"Robert Borthwik made me in the castel of Edinbrugh in the year of grace MDXXV."

Edinburgh seems to have enjoyed uninterrupted tranquillity during the remaining period of King James's reign. When he died, in 1625, the ministers of the city eulogized him as the "most religious and peaceable prince that ever was in this unworthy world." After the accession of Charles to the throne, which was proclaimed at the cross by the officers of state, a convention was held; and the town-council, in consequence of certain ships of war being wanted, and forts for securing the coasts, not only agreed to advance

the assessment when called upon, but also to contribute towards the maintenance of 10,000 men. Some time afterwards, a subsidy for four years having, at the king's desire, been granted by parliament, the inhabitants of Edinburgh generously advanced at once their quota, amounting to L.40,000 Scots. For these acts of kindness His Majesty expressed his gratitude by sending a sword and gown to be worn by the provost in the manner appointed by his father. Like his father, too, Charles resolved to visit his native country, and though prevented for some years from fulfilling his design, he at last accomplished it in 1633. He was received by the inhabitants with much pomp, and the celebrated Drummond of Hawthornden was appointed to address him on his arrival, which he did with all the characteristic poetical embellishment peculiar to the times. On the 18th of June, Charles was crowned in the Abbey Church of Holyrood, and on the 20th he assembled his first Scottish parliament in the Parliament House. During his residence in the city on this occasion, Charles erected the bishopric of Edinburgh, a measure which was by no means popular, and gave rise throughout the country to a series of civil disturbances, the principal focus of which seems to have been Edinburgh. During the civil war in 1640, the magistrates fortified the town against the castle, and disciplined the citizens. The governor, on perceiving these demonstrations of hostility, fired upon the city; but being soon afterwards besieged by General Leslie, he was compelled to surrender from want of provisions.

Charles visited the city a second time in 1641, and was received and entertained by the magistrates with the utmost deference and respect. A parliament met on the 15th of July, the result of whose proceedings was an entire change in the government, Charles retaining only the name of king, and the kingdom only the appearance of a monarchy. He agreed to an act of oblivion, by which his opponents were pardoned at the expense of his friends; and after a residence of four months in the northern metropolis, he returned to London, having intrusted his Scottish affairs to a committee of the estates. Two years after this, in the month of July, the Solemn League and Covenant for the extirpation of prelacy was signed in the High Church; and shortly afterwards the city raised and supported a regiment of 1200 men, to assist the English parliamentary forces against Charles, at a cost of L.60,000 Scottish money. For this and several other acts of hostility to the king, the town was in 1645 threatened with a visit from the Marquis of Montrose; but it was saved from this disaster by the breaking out of the plague, which committed great ravages amongst its population. This was, however, the last visit which this dreadful scourge paid to the metropolis. Shortly after this the city borrowed L.40,000 Scots to raise troops for the national engagement in favour of Charles; which debt they afterwards refused to pay, on the plea that it was contracted in an unlawful cause. The impartial justice of Cromwell, however, subsequently compelled them in 1652 to repay the money. In May 1650 the Marquis of Montrose was conveyed a prisoner into Edinburgh. Three days afterwards he was brought to trial, condemned to death, and suffered on a gallows erected at the cross. Two months subsequently Charles II. was proclaimed on the same spot; and in the end of September following, the town was in the possession of Cromwell. On this occasion the magistrates fled to Stirling, then the headquarters of the king's forces. The town was thus left without any other civic rulers than that of a body of 30 citizens, chosen by the inhabitants to discharge in part the functions of the magistracy, who absented themselves from the 2d of September to the 5th of December 1651. About this period the town-council granted liberty to one Adam Woodcock to establish a stage-coach between Edinburgh and Leith; which is amongst the first notices of a public conveyance of the kind in Scotland.

On the 11th of May 1660, the magistrates sent the town-clerk to Charles, who was at Breda, expressing their concurrence in his meditated restoration, already agreed to by both houses of parliament in England, and their joy at the prospect of such an event. Their messenger "had a most gracious reception;" and, in the name of the burgh, presented "a poor myte of L.1000, which he did graciously accept, as though it had been a greater business." The feelings of delight which the arrival of the king in England excited in Edinburgh, were expressed in the customary mode of costly feasting, a sumptuous banquet having been served up by the town-council at the cross. This attachment on the part of the citizens was ill requited by Charles, who, in settling the affairs of the kingdom, re-established episcopacy in Scotland, in opposition to the oath and obligation of honour by which he was bound. It is not surprising, therefore, that the Scottish people, so attached to Presbyterianism, should have expressed their indignation at his conduct in the most open manner. But when the liberty of the press, and freedom in matters of religion, were in consequence also speedily infringed upon, the whole country rose in arms, particularly the western counties. The attempt, however, which was made upon the life of Archbishop Sharp in the streets of Edinburgh, led to those milder measures which were soon afterwards adopted by government. In 1679, James, then Duke of York, came to reside in Edinburgh, and took up his abode in the palace of Holyrood, where he remained till May 1682. During this period he rendered himself extremely odious by his opposition to the Covenanters, and by his attempting the revival of the drama, and encouraging other amusements to which the people were exceedingly averse.

Two years after this, the magistrates set up for the first time a regular state carriage; and were so much pleased with the accommodation and conveniency of this novelty, that they ordered two coaches from London for their own especial use, with the addition of four horses. On the demise of Charles II. in 1685, the town-council erected an equestrian statue to him in the Parliament Square, as a proof of their gratitude to and affection for that monarch. Soon after James's accession, the unfortunate Earl of Argyll was brought a prisoner to Edinburgh; and after being ignominiously paraded through the streets, his head was struck off by the Maiden, this being the last time, it is believed, that the instrument was employed. After a series of disturbances and tumultuary proceedings, occasioned by the attempts of James VII. to restore the Roman Catholic religion, a convention of estates was held at Edinburgh, in which it was declared that James had forfeited the crown; and in March 1689 it was offered to William and Mary.

In 1696 Edinburgh was deeply interested in the celebrated Darien expedition, and was full of the high anticipations which this speculation had diffused throughout Scotland. About L.400,000 sterling were subscribed in the country. Six ships of considerable force and burthen, and laden with various commodities, sailed from the Firth of Forth; and in 1699, when intelligence arrived of the settlement being formed, the rejoicings in Edinburgh were unbounded. On the other hand, the disappointment excited on learning in the following year of its failure, filled the streets for several days with tumult and riot; and the city altogether presented such a scene of lawless anarchy, that the commissioner and officers of state deemed it necessary, for their personal safety, to retire until the popular fury had somewhat abated.

In 1704, on the occasion of a Captain Green and two of the crew of the Worcester, connected with the East India trade, being convicted, on circumstantial and insufficient evidence, of piracy and murder on the high seas, a commotion was excited by an apprehension on the part of the populace that they were to be permitted to escape the consummation

Edinburgh. of their sentence through the connivance of the authorities. The lord chancellor, in passing from the privy-council in his coach, was attacked at the Tron Church, the glasses were broken, and he himself was dragged from the carriage. He was rescued by some of his friends; but it was found necessary to sacrifice the seamen to the resentment of the populace. The year 1703 had been distinguished by its presenting the last exhibition of the ancient Scottish national pageant called the Riding of the Parliament, which took place on the 6th of May: in 1704 the inhabitants of Edinburgh were gratified by another ceremony quite in accordance with the spirit of the age, when, under the authority of an act of the privy-council, a large quantity of vestments, beads, chalices, crucifixes, and other appurtenances of Catholic worship, were brought to the cross, and there publicly burnt before the eyes of a delighted populace.

The tumults to which the city had been so frequently subject were revived in 1706, on the occasion of the proposed union of the kingdoms. This, as is well known, was at first vehemently opposed by the Jacobites and ultra Covenanters in Scotland, and gave rise to a series of the most violent and outrageous proceedings on the part of the mob, in order to intimidate those members of the Scottish parliament who were favourable to the measure. The deed, however, was finally accomplished, though not without great danger to the lives of its most active promoters. On the 6th of March 1707, the act received the royal assent in the House of Lords.

In the civil war of 1715 an unsuccessful attempt was made by the Jacobites to surprise the Castle. About this period the provost received a regular salary of L.300 per annum in order to defray his expenses; and in 1718 the scheme which had for some time been framed of extending the pier and building docks at Leith was in part executed; the town's debts, which even then amounted to L.25,000, being thereby, in the space of five years, nearly doubled.

The celebrated tumult designated the Porteous Mob took place in September 1736. The accounts of this remarkable affair are so numerous, so easily accessible, and withal in general so full, that it is deemed unnecessary to give more than a mere outline in this place. Porteous, whose name distinguishes the transaction, was captain of the city guard. At the execution of a criminal of the name of Wilson, whose fate had excited an extraordinary sympathy, Porteous, dreading a rescue by the mob, who suddenly became tumultuary, ordered the guard to fire on them. Six people were killed by the discharge, and eleven wounded. For this Porteous was tried and condemned to death; but he was afterwards reprieved by Queen Caroline, then regent. Resolved however that he should not thus escape the fate which they conceived he merited, the mob, on the evening of the day previous to that on which he was to have been executed, broke into the jail in which he was confined, and having dragged him out, led him to the Grassmarket, the usual place of execution at that period, and there hanged him by torch light on a dyer's pole.

On the 17th September 1745, a party of the Highlanders having made themselves masters of the Netherbow Port, Edinburgh was taken possession of by the rebels under Prince Charles Edward. The main body of the rebel army arrived shortly afterwards at the King's Park, headed by the Chevalier in person, who took up his residence in Holyrood, where he held open court, and was visited by great numbers of the inhabitants. The city remained on this occasion in the hands of the rebels till the 31st of October, when, finding it impossible to reduce the castle, they proceeded on their march towards England.

The public transactions of an historical nature which occurred in the metropolis after these events, are not, except in a few instances, such as to require a particular description. On the 2d of February 1779, an infuriated mob, under the influence of religious fanaticism, burnt one Roman Catholic chapel and plundered another. Twelve years later, on the outbreaking of the revolution in France, a considerable body of the inhabitants manifested their admiration of the new political principles which were then brought so prominently forward, by forming themselves into associations for supporting the cause of political regeneration. These societies, the members of which received the appellation of Friends of the People, at length drew down upon themselves the notice and vengeance of government. Several persons accused of having been concerned in spreading sedition, and engaged in treasonable practices, were arrested and brought to trial. One of them, named Watt, was condemned and beheaded, whilst others were transported. Subsequently, during the war with France, the citizens showed great zeal in support of the government, by forming themselves into regiments of volunteers, consisting of yeomanry, artillery, and several corps of infantry. On the last night of the year 1811, being the season devoted to innocent festivity, the streets of Edinburgh were disgraced by a series of riots, outrages, and robberies, hitherto unparalleled. During almost the whole night, after eleven o'clock, a gang, principally composed of young men, armed with bludgeons and other weapons, infested some of the principal streets of the metropolis, and knocked down, robbed, and otherwise wantonly maltreated almost every person who had the misfortune to fall in their way. In the dreadful tumult and scuffles which ensued, one officer of police was killed and many persons dangerously wounded, some of whom died in consequence, whilst a great number received severe contusions. Several rioters were seized, and being brought to trial, three were condemned and hanged, whilst some others were transported. This fearful outbreaking of juvenile delinquency led to the adoption of several beneficial plans for the better instruction of the lower classes, the benefits of which still continue to be felt.

George IV. visited Scotland in 1822, and spent upwards of a fortnight in the metropolis, inspecting its public institutions, and receiving the congratulations of his Scottish subjects.

In 1824 the city suffered from a series of conflagrations of a most destructive and appalling description. The first of these commenced on the 24th of June, when some of the private dwellings in the Parliament Square, with a part of the High Street, and several closes, were consumed. The second and the most extensive began on the evening of the 15th November, and continued for three days, destroying an immense number of houses, chiefly between the High Street and Cowgate, also several fronting the High Street at the Cross, another portion of the Parliament Square, and likewise the spire of the Tron Church, which had accidentally caught fire from the flying brands.

In no part of the United Kingdom was the passing of the Reform bill hailed with more heartfelt demonstrations of joy than in Edinburgh. The first election of members of parliament by the citizens took place at the cross on the 21st of December 1832.

The only important event of interest in the subsequent history of Edinburgh is the "Disruption" of the Church of Scotland, which formally took place at the General Assembly convened in St Andrew's Church, George Street, May 18, 1843.

The city: its position. Edinburgh is surrounded on all sides excepting on the north, where the ground slopes gently towards the Firth of Forth, by lofty hills. On the east, in the immediate vicinity of the city, are the abrupt and rocky elevations of Arthur's Seat, Salisbury Crags, and the Calton Hill, the first of which rises to the height of 822 feet above the level of the sea. On the south are the Braid and Pentland Hills, and on the west is the hill of Corstorphine. Salisbury Crags form a con-

Edinburgh. tinued range of naked and perpendicular cliffs, which rise like a mural crown from the summit of the hill, and at a distance have a singularly wild and romantic appearance, the interest of which is heightened by the contrast of the splendid city over which they tower majestically. The town stands on high and uneven ground, being built on three eminences, which run parallel to one another from east to west. The most elevated of these, on which the city was originally built, is terminated abruptly on the west by a precipitous rock surmounted by the castle, whilst to the east it gradually inclines to the plain from which rises the lofty elevation of Arthur's Seat. The valley to the north of this ridge, which was formerly filled with water, has been of late years drained, and is now laid out in public gardens.

Rise and progress of the city.

Till the middle of the eighteenth century, Edinburgh continued to occupy little more than the same space of ground which it had covered in the reigns of James III. and James IV., namely, the ridge between the Castle on the west and Holyrood House on the east, with the hollow called the Cowgate on the south, and part of the rising ground beyond. This was surrounded by a wall with several gates, or ports as they were called, a considerable part of which is still to be seen in the Vennel, leading from Lauriston Place into the Grassmarket. In a great proportion of this Old Town the buildings are crowded and irregular, and the houses in some parts rise to the unusual height of eleven stories. The principal, or High Street, which is somewhat more than a mile in length, and is in some parts ninety feet in breadth, occupies the centre of the ridge, and extends, under different designations, nearly in a straight line from the Castle on the western extremity to the Palace of Holyrood on the eastern. Both sides of the ridge occupied by this street are covered with buildings crowded together in the closest array, and descending from the High Street, chiefly in narrow lanes, or closes as they are termed, which are seldom broader than six feet, and which, consisting of high houses on either side, are inhabited by numerous families, with little regard either to health or cleanliness. A proposal in the reign of Charles II. to extend the town over the lands to the north, beyond the hollow called the North Loch, having been frustrated, nothing was done till 1751, when an old building having fallen, by which one person was killed, a strong feeling regarding the inconvenience and decayed condition of the houses began to be expressed. The first decided step towards extending the city was taken by Provost Drummond, on the 21st of October 1763, when he laid the foundation-stone of what is now styled the North Bridge, in order to connect the town with the properties on the north. This edifice consists of three great arches, each 72 feet in width and 68 in height, with small side arches, making the total length 310 feet. In 1767, whilst this work was proceeding, an act for extending the *royalty* was obtained; and a plan for the New Town being then formed by Mr Craig, architect, the foundation of the first house was laid on the 20th of October the same year. By this plan the chief streets of the New Town of Edinburgh were disposed in three parallel lines from east to west, intersected by cross streets at right angles from north to south. Princes Street, on the south side, is formed like a terrace, facing the Old Town; a similar street, facing the north, is called Queen Street; while George Street is in the centre. Charlotte Square, at the west end of George Street, corresponds with another at its eastern extremity, designated St Andrew Square. Coeval with the erection of these, a spacious street was opened from the extremity of the North Bridge and Princes Street, towards Leith Walk, or main road to Leith, opening an excellent communication with that seaport. The whole of the new edifices, according to Mr Craig's plan, were completed about the year 1815, but the greater part much earlier.

Such was the success attending the building of the New Town, that in time a second extension of the same nature was projected, still farther towards the north, beyond an open area in front of Queen Street. The design of this second town intimately resembled that of its predecessor, consisting of a terrace in front and rear, a large central street, with two intermediate narrow ones, and cross streets in continuation of those in the former New Town. This vast and splendid addition to Edinburgh was commenced in 1801, and was nearly finished in the year 1826.

Edinburgh.

About the time when the second New Town approached its completion, a series of superb edifices began to be erected on its north-western confines, between Charlotte Square and the Water of Leith, on the Earl of Moray's property of Drumsheugh. This magnificent part of Edinburgh was erected during the years 1823, 1824, and 1825. This quarter of the town was greatly improved by the erection, in 1832, of the Dean Bridge, consisting of four arches, stretching across the deep dell or ravine at the bottom of which flows the Water of Leith.

The extension of the New Town to the north and west absorbed public attention till about the year 1813, when the idea was started of opening an entrance from the east. The foundation-stone of the Regent Bridge, to form a connection with the Calton Hill, was laid in September 1815, and the work was completed in 1819. The arch of this structure is 50 feet wide, by about the same in height. On the top of the ledges of the bridge are arches and ornamental pillars of the Corinthian order, which on both sides are connected with the houses in the line of street formed at the same time. The street, or Waterloo Place as it has been designated, is composed of very superb houses of four stories, and each is terminated at Princes Street by a pediment and columns above the lower story. From Waterloo Place, the new road by which most of the vehicles and passengers from the east enter the city, proceeds by a sweep round the southern face of the Calton Hill. The entrance by this thoroughfare is not less commanding and beautiful than that by the west; and the houses in segments of circles, forming the Royal and Regent Terraces, erected on the slope of the hill, have a very striking effect.

Some years prior to the foundation of the New Town, certain private proprietors began to build lines of houses, of a good style of architecture, on the grounds to the south of the Old Town; and in this way George Square, Argyle Square, and Brown Square were opened for the reception of the higher class of citizens. The erection of these and other edifices soon suggested the necessity of a proper communication between them and the High Street, on the plan of the North Bridge; and on the 1st of August 1785, the foundation-stone of a bridge crossing the Cowgate, styled the South Bridge, was laid, and the thoroughfare opened for passengers in March 1788. The South Bridge consists of twenty-two arches, all of which are concealed by the buildings along its sides, with the exception of one at the centre spanning the Cowgate. The formation of the Union Canal, to serve as a water communication with Glasgow, by joining the Forth and Clyde Canal, took place in virtue of an act of parliament procured in 1817 by a joint-stock company. Its eastern termination is about half a mile S.W. from the Castle, near the present terminus of the Caledonian railway. This locality was greatly improved by the formation of the New West approach and Castle Terrace. The greatest recent improvement in Edinburgh has been the construction of the four railways that leave it on each side; the Edinburgh and Glasgow on the west, the North British on the east, the Caledonian on the south, and the Edinburgh, Perth, and Dundee on the north. With the exception of the Caledonian, the stations are concentrated at Waverley Bridge, a most convenient locality, situated in the hollow between Princes Street and the Old Town.

At the present day the city extends about two miles in

Edinburgh.

length and the same in breadth; but with Leith, and the suburbs of Newington, Morningside, Inverleith Row, and Trinity, about $2\frac{3}{4}$ miles by $3\frac{1}{2}$ miles.

Public buildings and institutions.

The Castle, as has already been stated, owes its origin as a regular place of defence to the Anglo-Saxon dynasty, near the end of the fifth century; but its fortifications appear to be of comparatively modern date. The rock, surmounted by battlements, lofty barracks, and other buildings, rises to a height of 300 feet, and is precipitous on all sides except the east, on which it is connected with the town by an open glacis or esplanade. In a small apartment on the ground floor of the palace erected by Queen Mary, that princess was delivered of her son, James VI., on the 19th of June 1566. In the same part of the edifice is situated the crown room, where the regalia of Scotland were lodged in 1707, and found in 1818, after being lost sight of for upwards of one hundred years. These regalia consist of a crown, sceptre, sword of state, and lord treasurer's rod: the former is supposed to be even more ancient than the time of Robert Bruce, though it has undergone several changes since that period; the sword was a present from Pope Julius II. to James IV. The arsenal or storehouse of the Castle is capable of containing 30,000 stand of arms, and the whole buildings about 2000 men. In March 1829 an addition was made to the curiosities of the castle by the restoration of an ancient piece of ordnance called Mons Meg, which had been removed from the fortress and carried into England in 1754. This immense cannon, for it is of an unusual size, was fabricated in the year 1498, and is curious from its structure, being formed of bars bound together with rings. It was employed at the siege of Norham Castle, but was rent in 1682, when firing a salute in honour of James Duke of York.

Holyrood.—The charter of foundation of the Abbey of Holyrood has no date—the Abbey however was founded about the year 1128. It was largely endowed by the founder David I., and was considered as one of the wealthiest ecclesiastical establishments in Scotland. In 1544 it was sacked, and in part destroyed, by the Earl of Hertford when he invaded Scotland; and again in 1547. The nave used as a chapel was desecrated and dismantled by the mob in 1688; and in 1768 the roof fell in, and it was left in the ruined condition in which it now stands. Within this chapel were interred, amongst others, David II., James II., James V., his queen Magdalen, and Darnley. The royal palace is contiguous. It is not known at what time a palace was first erected on this spot. The more ancient parts of that which is now in existence were built by James V.; but it has since undergone many changes, and little if any of the original building remains. It was burnt by the soldiers of Cromwell, and was rebuilt after the Restoration by Charles II. The architect on this occasion was Sir William Bruce, and the builder who carried his designs into execution was Robert Mylne. The edifice is of a quadrangular figure, with an open court in the centre, surrounded with piazzas. Amongst the curiosities exhibited in the Palace of Holyrood is the chamber of Queen Mary, in which may still be seen, though in a decayed state, the bed of that unfortunate princess. In a hall or gallery 150 feet in length, $27\frac{1}{2}$ in breadth, and 18 in height, containing 106 mythical portraits of Scottish monarchs, the election of representative peers for Scotland takes place. The most remarkable circumstance connected with Holyrood House is its privilege of affording a sanctuary to debtors. The limit of this privileged territory is marked in the direction of the town by a channel or gutter at the foot of the Canongate, and at the distance of about 100 yards from the palace. Altogether the sanctuary describes a circle of about five miles, including Salisbury Crags and Arthur's Seat. The immunities of the sanctuary have existed since the date of the monastery. Considerable improvements were made on the exterior walls of the palace during 1832, and some years previously. The locality has also been greatly improved recently by the removal of many of the surrounding old houses, which, with the numerous additional repairs and alterations in the palace that have been made lately, render it an agreeable residence for her present Majesty Queen Victoria.

Edinburgh.

Courts of Law.—Edinburgh is now chiefly distinguished as a capital by being the seat of the Scottish supreme courts or College of Justice, which, as has already been mentioned, was constituted in 1532 by James V. This body consists of persons intimately connected with the various supreme courts, and comprehends the judges or senators, the faculty of advocates, writers to the signet, solicitors in the supreme courts, advocates' first clerks, clerks to the judges, extractors, keepers of the different departments, &c. This influential body at one time possessed some valuable privileges, the chief of which now remaining is exemption from certain local taxes.

The Parliament House.—The edifice, which has been appropriated since the Union as the place of meeting of the supreme courts, is the old Parliament House of Scotland, situated in the centre of the Old Town, and separated from the High Street by the cathedral of St Giles. This structure was erected between the years 1632 and 1640, at an expense of L.11,600 sterling to the civic corporation. In recent times, however, with the exception of the great hall, it has been almost totally renewed. It stands on the southern and western sides of the inclosure called the Parliament Square, a place formerly surrounded with the shops of tradesmen, but entirely remodelled since the destructive fires of 1824. These improvements, which extend over the front of the old parliament house, or present court-house, have been executed chiefly by government at a great expense. The entrance to the courts is at the south-west angle of the square: the great hall is 122 feet by 49, and has a lofty roof of carved oak, arched and trussed in an admirable style of carpentry. This hall is the waiting-room of the advocates and other practitioners in the Supreme Courts; and the floor during session is the daily resort of all persons connected with them. The Lords Ordinary sit in small court-rooms at the south end of the hall. On a pedestal near the south end of the hall is a statue in white marble by Chantrey of Henry Viscount Melville, who died in 1811; and in recesses in the walls other statues have been placed, including those of Duncan Forbes of Culloden, erected in 1752, five years after his death, of Robert Dundas of Arniston, who died in 1819, and of Robert Blair of Avontoun, who died in 1811; the last also by Chantrey. More recently additional niches have been prepared for the reception of the statues of Lord Jeffrey and President Boyle.

Adjoining the Parliament House are certain spacious apartments fitted up as libraries for the Faculty of Advocates, the Writers to the Signet, and the Solicitors of the Supreme Courts. The Advocates' Library was founded in 1682, at the instance of Sir George Mackenzie, then Dean of Faculty. The collection is now the largest and most valuable in Scotland, and is in every sense one of the noblest national libraries. It is one of the five libraries entitled by act of parliament to a copy of every work printed in Britain; and, with the sums annually disbursed in the purchase of useful and rare books, it is rapidly increasing. The library is under the charge of six curators, a librarian, and assistants.

The Library of the Society of Writers to the Signet occupies a modern erection of two stories, in the Roman style of architecture, extending westward from the north-west corner of the Parliament House, and having a front to the Lawnmarket. This edifice contains two large and beautiful apartments, decorated in front of the book-presses with rows of columns. These noble apartments have cost the society L.25,000. The library, like that of the Advocates, is under the charge of curators, a librarian, and assistants.

Register House.—The Scottish Supreme Courts possess accommodations for their records, and the functionaries connected therewith, in a building styled the General Register House of Scotland, one of the most remarkable national edifices in the metropolis. It stands at the eastern extremity of Princes Street, fronting the thoroughfare of the North Bridge. The foundation was laid on the 17th of June 1776, and L.1200 were given by George III. out of the money arising from the sale of the forfeited estates, to assist in its erection. It was fully completed in 1822, at a very great expense, which has been defrayed by an accumulation of fees paid by persons searching the records, and for writs in the chancery office. The building, which was planned by Mr Robert Adam, forms a square, with a quadrangular court in the centre, containing a circular edifice or dome fifty feet in diameter, which joins the sides of the court, leaving spaces at the angles for the admission of light. Viewed from the street, it presents a compact building of 200 feet in length, by a breadth of 120. Each of the corners is surmounted by a small turret, and the central tower is crowned with a dome. The interior consists principally of small fireproof chambers, in which are deposited state papers, copies or records of all the title-deeds of property, and of all legal contracts, mortgages, &c.; also records of all suits at law from an early period. In front of it is an equestrian statue of the Duke of Wellington in bronze by Steele.

Royal Institution.—In looking along the noble line of Princes Street, the eye is arrested by two structures upon the Earthen Mound—the Royal Institution and the National Gallery—both of which were designed and executed by Mr W. H. Playfair. The Royal Institution was originally founded in 1823, but was enlarged, by an extension towards the south, in the year 1832, which was completed in 1836. It is of the Grecian Doric order, of the era of Pericles, and is designed upon the theme of a peristylar temple. The great projection of the north portico surrounded and filled with columns, and the long ranges of pillars upon each flank, preserve the columnar richness of the original; while the necessary departure from the simple parallelogram, caused by the necessities of the plan, is compensated by the introduction of small side porticos of classic design. A statue of the Queen in stone by Mr John Steele, R.S.A., is placed on an attic immediately behind the northern portico. The building, which fronts the opening of Hanover Street, is the property of the Board of Trustees for Manufactures in Scotland; and besides furnishing official apartments for the Board and galleries for the School of Design under their charge, is appropriated by them for the accommodation of the following institutions:—The Board of British White-Herring Fishery; The Incorporation of the Royal Institution for the Encouragement of the Fine Arts in Scotland; and the Royal Society; to which will be added the Society of Antiquaries as soon as the adjoining building of the National Gallery is completed.

The interior accommodations consist below of a large central gallery for exhibitions, the ends of which are formed into octagons of some size. On both sides of this gallery is a range of smaller apartments, those on the east side being reserved as offices for the Board of Trustees and for the Board of Fishery, and those on the west being tenanted by the Royal Society. Above is another spacious gallery in which is a noble collection of casts from the best ancient works of sculpture, with some of modern date. This gallery, along with the adjoining apartments, is occupied by the School of Design. In one of the apartments is contained the admirable set of busts of celebrated Greeks and Romans, known by the name of the Albacini Collection. In the picture gallery is deposited a small but valuable collection of works by ancient and modern masters, among which are some very fine specimens of Vandyck, and in the modern section some masterly paintings by Etty. The collection since its first formation has been enlarged by the addition of the pictures, bronzes, and marbles belonging to the late Sir James Erskine of Torrie, who bequeathed them to the college at Edinburgh, for the purpose of laying a foundation for a gallery for the encouragement of the fine arts; and in the year 1845, with the consent of the Senatus Academicus, an agreement was entered into between the trustees of Sir James Erskine's will and the Board of Trustees for Manufactures, that the collection should be placed in the Royal Institution for public exhibition, where it passes under the name of "The Torrie Collection." The whole of the collections are increased from time to time by gifts or purchases of works of art, or by their temporary deposit in charge of the Board for the purpose of exhibition. The galleries are opened gratuitously to the public; the statue gallery for five days in the week, and the picture gallery for two. On other days the picture gallery is reserved for the use of artists and students.

The Board of Trustees for Manufactures owes its origin to the 15th article of the Treaty of Union between England and Scotland, by which, amongst other provisions by way of equivalent for the increase of the duties of excise and customs then imposed on Scotland, it was agreed that out of certain funds therein mentioned, L.2000 per annum should be applied towards the encouraging and promoting of the fisheries, and such manufactures and improvements in Scotland, as might most conduce to the general good of the United Kingdom; which grant was afterwards made payable out of the customs and excise in Scotland. The Board itself, however, was not constituted until the year 1727, when letters patent were issued by King George II, empowering it to administer this grant upon which accumulations had arisen in previous years so as to form a reserve fund. By the original letters patent the Board was made to consist of 21 trustees: these were afterwards increased to 28 by the act 48 Geo. III., cap. 110. They are chiefly gentlemen of distinction and property, judges of the supreme courts, &c.; and at the present moment three members of the Royal Scottish Academy have seats at the Board. Vacancies are filled up by the crown; five members form a quorum; and meetings are held periodically throughout the year. For many years the Board made specific appropriations of the monies at its disposal, half being usually allotted to the improvement of the fisheries until a separate Fishery Board was established in 1809, the other half to premiums and other measures for the encouragement of the linen and hempen manufactures. Ultimately this system was abandoned, and the funds have now for a long while been almost entirely appropriated to the maintenance of a School of Design, which is justly regarded as the most effective method of permanently improving the arts and manufactures of the country.

This school had its commencement in 1760, when a drawing academy on a small scale was formed, and placed under the direction of M. Delacour, a French artist. He was succeeded in 1768 by M. Pavillon, another French artist. Runciman, an eminent Scottish artist, was appointed in 1772; who, in 1786, was succeeded by David Allan, a Scottish artist of great genius. Under his successor John Graham were brought up Wilkie, Burnet, the late Sir William Allan, and the present President of the Royal Scottish Academy, Sir John Watson Gordon. The sphere of the school has been enlarged of late years, so as to be converted from a drawing academy into a School of Design, embracing, besides the study of the antique, the art of manufacturing design and of architectural and general ornament. In this stage, it has been successively superintended by Andrew Wilson, Sir William Allan, William Dyce, and Thomas Duncan, and is now (1855) directed in architecture and ornament by Alexander Christie, A.R.S.A., and in the antique by Robert Scott Lauder, R.S.A

Edinburgh. In the department of architecture and ornament this school gives instruction in drawing, painting, and modelling, and in architectural and ornamental design of every kind; and in the department of the antique, in drawing, painting, and modelling from the antique; and also from the living model. There are upwards of 180 students attending the school, who are divided into separate male and female classes. Among these, besides the ordinary students, are several schoolmasters and schoolmistresses and pupil teachers; so that the establishment has the character of a normal institution for drawing and painting, as well as that of a school for art. The Board of Scottish White and Herring Fisheries has also apartments in this building. See SCOTLAND, and FISHERIES.

The National Gallery, the foundation stone of which was laid by Prince Albert in August 1850, was finished externally in 1854. It is of the Greek Ionic order, and has a central mass with large hexastyle porticos to the east and west. At each side of this central portion, stretching to the north and south, ranges of antæ are terminated by smaller tetrastyle porticos which form the north and south fronts of the building—two porticos separated by a recessed portico being upon each front. The absence of windows on the flanks increases the classic aspect of the entire building. It was erected at the joint expense of the Board of Trustees for Manufactures and of the Government, under arrangements made with the Lords Commissioners of Her Majesty's Treasury, and confirmed by act of parliament. The Government have made a grant of L.25,000 towards the building, and the Board of Trustees have undertaken to furnish other L.15,000. Its objects are the giving of suitable accommodation for the annual exhibitions of the Royal Scottish Academy, for the extension of the School of Design, and for the institution of a Scottish National Gallery of Painting and Sculpture, and thus to promote the successful progress of the fine arts in Scotland, and afford facilities to the public for viewing exhibitions and collections of modern and ancient art. The site was purchased in part from the city of Edinburgh and in part from the Free Church. By the act 13th and 14th Victoria, cap. 86, the whole of the property and buildings have been vested by parliament in the Board of Trustees, who are appointed to determine and regulate the appropriation thereof, subject to the approbation of the Lords Commissioners of the Treasury.

Royal Institution for the Encouragement of the Fine Arts.—This Institution had its origin in the year 1819 as a private association formed for the encouragement of the fine arts in Scotland, on the model of the British Institution of London. It was not an association of artists, but of noblemen and gentlemen admirers of art, who were desirous by their united pecuniary contributions and personal influence to diffuse a taste for art among their countrymen. The first aim of the institution was to furnish exhibitions of the pictures of ancient masters, drawn from the private collections of members and their friends, and to which, at the same time, professional artists should have private access for the purposes of study. Exhibitions of this nature accordingly took place in the years 1819 and 1820. In 1821 it was suggested that an exhibition of the works of living artists should for that year be substituted, and the exhibitions of modern paintings were continued during the years 1821, 1822, 1824, and 1825. The institution had found great difficulty in procuring commodious rooms for the purposes of exhibition; and when it was subsequently arranged that a building should be erected at the expense of the Board of Trustees for Scottish Manufactures, and that other public societies should become their tenants, the Royal Institution obtained under this arrangement the galleries which were first opened in the year 1826. In March 1827 the institution was incorporated by royal charter from the crown by the name and title of the Royal Institution for the Encouragement of the Fine Arts in Scotland. The charter contains the following provision in regard to the application of the funds:—"The ordinary directors shall be entitled to apply the funds of the institution for the purpose of acquiring such property and buildings as may appear to them necessary and proper for the objects of the institution, and in the purchase of the works of art and books for the institution, and, generally, in such manner as they may consider to be expedient for the encouragement of the arts in Scotland."

The management of the Royal Institution is vested in governors and extraordinary and ordinary directors, a secretary, treasurer, and manager. The directors are likewise trustees for the Spalding Fund for the purpose of providing annuities for decayed and superannuated artists.

This fund was left by the late Peter Spalding, Esq., by his will dated 12th June 1826, and the directors of the Royal Institution were intrusted with its management as trustees. The fund is a limited one, and from the annual proceeds, which amount to about L.200 a-year, annuities are granted to artists rendered incapable, by sickness or age, of maintaining themselves.

The Royal Scottish Academy of Painting, Sculpture, and Architecture was instituted in 1826, and incorporated by royal charter in 1838. It was formed, with some modifications, on the plan of the Royal Academy in London, and its success has been very remarkable, as, besides considerable funds, it has accumulated a valuable collection of pictures, which are made available to the public gratuitously. As yet the academy has received no assistance from government, but its efforts have been favourably recognised, and it is to be placed in Scotland in a position analogous to that held by the Royal Academy in England. The Royal Scottish Academy is not merely the only successful fine-art body in Scotland, but there is no other society in the whole kingdom, out of London, that possesses sufficient vigour within itself to be able to place before the public an exhibition of works, almost all of which are contributed by its own members or artists who have enrolled themselves as candidates for membership.

The Royal Association for the Promotion of the Fine Arts in Scotland.—The first of the societies now generally known in this country under the name of "Art Unions," was founded in the year 1834, and was incorporated by royal charter in 1847.

The association is composed of annual subscribers of one guinea and upwards, and the funds are appropriated to the purchase of modern works of art in painting, drawing, or statuary, and to the execution or purchase of engravings, bronzes, bas-reliefs, models, or other productions of art, for distribution among the subscribers, by lots publicly drawn at an annual general meeting which is held in July for that purpose. A portion of the funds is also devoted to the production of an engraving which is annually given to each subscriber, and to the acquisition of modern works of art, towards the formation of a National Gallery.

Eminent success has attended the association since its commencement; and to its animating influence must mainly be attributed the improved condition of art and artists in Scotland.

The Royal Society of Edinburgh was incorporated by royal charter in 1783, for the purpose of encouraging philosophical inquiry and discussing matters connected with nature and art. Its meetings take place on the evenings of the first and third Mondays of each month during winter and spring; and it has published twenty volumes of transactions. It is governed by a president, six vice-presidents, and twelve councillors. It possesses apartments, an extensive library, and a small museum, in the Royal Institution buildings.

The Society of Antiquaries of Scotland originated in

1780, and was incorporated by letters under the great seal in 1783. Their museum, or collection of antiquities, in the apartments No. 24 George Street, is open to visitors two days in the week on the most liberal terms; and by some arrangements recently made it will, upon the completion of the National Gallery, be transferred to the Royal Institution buildings as national property, but remaining under the custody of the society. The meetings are usually held on the second and fourth Mondays from December to May inclusive; and the proceedings are now printed annually for the use of the members.

The Highland and Agricultural Society of Scotland was the first institution of the kind in the United Kingdom, and the parent of the very numerous bodies which now devote special attention to the advancement of agriculture. The society's chambers are in Albyn Place, where also is the secretary's official residence. The museum and hall for public meetings are on George IV. Bridge; the former being open to the public free every day, except Monday, from eleven o'clock to three. (For particulars of this Society see SCOTLAND.)

Ecclesiastical institutions and buildings.

During the reign of episcopacy in Scotland, Edinburgh was the seat of a bishop. It is now the place of meeting of the General Assembly of the Church, and the seat of a synod and presbytery. Ecclesiastically, the ancient and extended royalty comprehend thirteen parochial divisions, eight of which have one clergyman each, and five are double or collegiate charges. That portion of the town which is not within these divisions belongs to one or other of the parishes of St Cuthbert's, Canongate, and South Leith. Originally the city consisted of only one parish, of which the ancient church of St Giles was the place of worship.

The fifteen city churches are the charge of the civic corporation, who appoint the ministers. The clergy, eighteen in number, are supported by an assessment, called annuity-tax, levied within the ancient and extended royalty on all houses and shops, with the exception of the dwelling-houses of the members of the College of Justice. This tax is six per cent. on the rental of the city, and has been levied for more than two centuries. During the last 100 years the sum so raised has exceeded L.400,000, which, it was urged in a statement of the lord provost, magistrates, and council, unanimously adopted 26th May 1851, should have been provided out of the proper ecclesiastical funds of the nation. This tax has long been a source of strife and heart-burning among the citizens, and many attempts have been made to get it abolished or equitably adjusted, but without effect.

The following statement (from the Report of Select Committee ordered by House of Commons to be printed July 1851—No. 617) shows the free proceeds of the annuity-tax and other revenues belonging to the ministers of Edinburgh, after deducting all the expenses of survey and collection payable in the collector's department; but without deducting the salary paid to the factor for the ministers, law expenses not recovered from parties prosecuted, and general law and miscellaneous expenditure in the department of the factor and law agent, on an average of seven years from Whitsunday 1844 to 1850:—

Average amount of assessment	L.11,168	7	5
Average amount of the annuity-tax collected, including arrears	8,811	6	2
Average expenses of survey and collection	580	15	4
Average net proceeds of the annuity-tax	8,230	10	10
Average net proceeds of the Leith revenue and Lady Yester's fund	2,008	6	8
Average total revenues belonging to the ministers	10,238	17	6
Average stipend to each minister, subject to the deductions above mentioned	568	16	6

Another statement from the same report, made up from the published accounts of the Free Church of Scotland, shows the average stipends of the 25 Free Church ministers of Edinburgh, for the years ended 31st March 1849, and 30th March 1850, including supplementary grants and sums received from the Sustentation Fund, to have been as follows:—1849, L.280, 18s.; 1850, L.289, 18s. 5d.

The following table, from the religious census of 1851, gives the statistics of the several sects in Edinburgh and Leith:

Religious Denomination.	Population of Parishes, . 193,929. Burghs, 191,221.			
	Places of Worship.	Sittings.	Attendants Morning.	Attendants Afternoon.
Established	26	19,994	8,674	6,887
Free	29	20,830	15,315	15,922
United Presbyterian	20	20,465	12,792	15,235
Episcopal	10	3,796	3,052	1,630
Roman Catholics	4	1,500	2.454	2,068
Independent	6	5,610	2,376	2,799
Relief Presbyterian	1	540	317	360
Original Seceders	1	900	250	350
Baptists	7	3,096	1,654	1,265
Friends	1	430	47	58

Isolated	8	1,070	750	155
Catholic and Apostolic Church	1	300	185	14
Latter Day Saints	...	...	...	...
Jews	1	67	28	...
Total	123	81,873	48,886	47,227

The evening attendance in the churches of Edinburgh was 11,319. And with regard to Edinburgh it is stated that the number of sittings is not returned for 17 places of worship—3 Established Church, 2 United Presbyterian, 3 Free Church, 3 Episcopalian, 1 Baptist, 2 Roman Catholic, and 3 isolated congregations; and returns are altogether wanting for 16 other places of worship—8 belonging to the Established Church, 2 Original Secession, 1 United Presbyterian, 1 Free Church, 1 Episcopalian, 1 Roman Catholic, 1 Evangelical Union, and 1 isolated congregation.

St Giles.—This venerable fabric, which occupies a prominent situation in the centre of the Old Town, on the south side of the High Street, is of unknown origin and date. It has been presumed that a church existed on its site as early as the year 854; but the first certain intelligence regarding it occurs in 1359, when a charter was granted by David II. bestowing some land on a chaplain who officiated at one of its altars. The building, previously to certain alterations which were made upon it, was cruciform, and of Gothic architecture, but rather substantial than elegant. From the centre of the whole there rises a square tower, the top of which is encircled with open figured stone work, whilst from each corner of the tower springs an arch, and the four meeting together produce the appearance of an imperial crown. These arches are highly ornamented with small pinnacles, and from the apex rises an equally ornamented short spire. This elegant object is prominent above the whole of the town; and being 161 feet in height, it may be seen at a great distance. After the Reformation, the church was divided by internal walls into separate places of worship. By these and other subsequent alterations, the choir or eastern division formed the High Church; the one occupying the centre of the building was styled the Old Church; another, entering from the south-west corner, the Tolbooth Church; and one at the north-west corner was named the New North Church. Between the years 1829–33 this extensive edifice was remodelled by an entire casing of new walls, and fitted for the accommodation of three churches, on a plan by William Burn.

Trinity College Church, which was next in point of anti-

Edinburgh. quity to St Giles, was removed from the low ground east from the North Bridge, by virtue of an act of parliament, procured by the North British Railway Company in 1846. It was founded in 1462 by Mary of Gueldres, widow of James II.; and in 1502 James IV. invested it with some additional revenues. At the period of the Reformation it shared the fate of the other ecclesiastical establishments of the kingdom. In 1567 the Regent Murray gave it to the town-council to "be ane hospital for the poor, to be biggit and uphaldane be the gude toun," and the council soon afterwards founded within its precincts the Trinity Hospital. When the building was taken down, the body of its royal foundress was disinterred from beneath the aisle on the north side of the church, and deposited in Holyrood Abbey; within its walls were likewise the remains of many persons celebrated in Scottish history. As this church was by far the finest specimen of ecclesiastical architecture in Edinburgh, being a noble fragment of the second-pointed style, arrangements were made when it was taken down for restoring it on a new site; and it is hoped that this design may be carried out, so as to continue a valuable architectural ornament to the city.

The Old Greyfriars Church was built in 1612, but it was not constituted a parish church till 1722. Previously to this, in May 1718, its spire was blown up by gunpowder, which had been lodged in it by the town authorities for security. It was destroyed by fire in 1845; but arrangements are in contemplation for its re-erection in uniformity with the New Greyfriars Church, to which it is contiguous. The New Greyfriars Church was built in 1721. Both of these buildings, which were separated only by a wall, were erected on what was formerly the garden ground of the monastery of Greyfriars, in the south part of the town, and which, on the demolition of the friary in 1559, was conferred by Queen Mary on the town, to be used as a public cemetery. The Old Greyfriars Church was remarkable as being the place where the National Covenant was begun to be signed in 1638, and as including amongst its ministers Robertson, the celebrated historian of Charles V.

The Assembly Hall, or *Victoria Hall* as it is sometimes called, was erected in 1843, as a place of meeting for the General Assembly of the Church of Scotland, and also to be used as one of the city churches. The spire is 241 feet high, and, from its elevated position, forms an elegant and conspicuous object from almost every point of view. The design is by Gillespie Graham; and the spire is one of the best specimens of modern Gothic architecture in the kingdom.

St John's, situated at the west end of Princes Street, is the most elegant Episcopal church. It was founded in 1816, and finished in two years at an expense of L.15,000. It is of the florid Gothic style, from a design by Mr Burn, measures 113 feet in length by 62 in breadth, and is terminated at the western extremity by a beautiful square tower, rising to a height of 120 feet. Another Episcopal chapel, of tasteful Gothic architecture, is that of St Paul's in York Place. It was designed by Mr Elliot, founded in 1816, and finished in 1818, at an expense of about L.12,000. It measures 122 feet by 73, and from each corner there rises a small circular turret. St Paul's Chapel, Carrubber's Close, is the oldest Episcopal chapel in Edinburgh, having been erected about the end of the seventeenth century.

Fducational institutions. *The University.*—Edinburgh has long derived celebrity from its educational establishments, the chief of which is the University. This institution was founded by James VI., by charter dated 24th April 1582, and the first professor was appointed in 1583. About the year 1660, by means of benefactions from public bodies and from private individuals, the establishment had attained a respectable rank among similar institutions. As a school of medicine it first rose into repute under Dr Alexander Monro, who became professor of anatomy in 1720; and in this branch of science it afterwards attained a distinguished pre-eminence, from possessing professors remarkable for their abilities and success as teachers. In the other branches of knowledge, its reputation was gradually exalted to the highest pitch by Maclaurin, Black, Fergusson, Stewart, Robertson, and other eminent men. The decay and insufficiency of the old buildings had long been complained of; and at length, in 1789, the foundation was laid of a new and extensive structure, the plan of which had been furnished by Mr Robert Adam. But this plan, after it had been partly carried into execution, was altered and modified; and the building has been finished in conformity with a very skilful and tasteful design furnished by W. H. Playfair. This edifice forms a parallelogram, inclosing an open court which is occupied with the class-rooms, the museum, and the library.

The number of professorships is thirty-two, and these are divided into four faculties, viz., theology, law, medicine, and arts. The latter includes all the chairs devoted to literature and general science. The principal and professors constitute the Senatus Academicus.

The magistrates and town-council are the patrons of the university, and have the nomination to the greater number of the chairs; the others are under the patronage of the crown, except three, the patronage of which is shared by the faculty of advocates, the writers to the signet, and the town-council. The degrees it bestows are the same as in the other Scottish colleges, namely, those of doctor of divinity, doctor of laws, doctor of medicine, and master of arts. The winter session commences on the 1st of November and closes at the end of April, and the summer session begins on the first Monday of May and terminates at the end of June. During the latter term the lectures given are confined to botany, natural history, medical jurisprudence, histology, and clinical lectures on medicine and surgery Those who wish to qualify for a degree in arts are required to attend the classes of humanity, Greek, logic, mathematics, moral philosophy, natural philosophy, and rhetoric. There are 34 foundations for bursaries, of the aggregate value of L.1172 per annum, for the benefit of 80 students. The number of students who matriculated in 1853–4 was 808, of whom 453 joined literary classes, 298 attended the medical faculty, and 57 were students of law.

The College Museum is particularly rich in objects of natural history, amongst which are specimens of from eight to nine thousand birds, foreign and British. The mammifera amount to about 950 specimens. The mineral and geological collections are of immense extent; but can only be partially exhibited for want of sufficient accommodation. The Museum occupies two large rooms, each ninety feet by thirty, besides minor apartments.

Her Majesty's government having resolved to establish in Edinburgh a National Industrial Museum, a first parliamentary grant was obtained for the purpose last session (1854), and a suitable site has been obtained adjoining the west end of the college.

The College Library consists of about 100,000 volumes. It is supported from a fund formed by the contribution of one pound exigible from every student who matriculates, five pounds payable by every professor on his admission, and a portion of the fees of graduates both in medicine and arts. It was besides entitled, along with the other libraries belonging to the Scottish universities, to a copy of every work published in Great Britain, instead ot which it now receives an annual grant of L.575. There is also an excellent collection of books on theology and church history connected with the class of divinity, and which is supported by certain annual fees paid by the students attending the class. The principal apartment, called the Library Hall, is 198 feet in length by 50 in width.

The Botanic Garden, which is connected with the chair

 of botany in the university, may be traced as far back as about 1670. It was founded by Sir Andrew Balfour and Sir Robert Sibbald, who enriched it in part with plants from the garden of Patrick Murray, baron of Livingstone. The garden was first confined to a small spot near Holyrood; it was afterwards transferred to the vicinity of Trinity Hospital, occupying the ground long known as the Physic Gardens, and now covered by railway buildings. In 1767 it was transferred to Leith Walk, and in 1822 it was removed to its present locality in Inverleith Row. It is the only Royal Botanic Garden in Scotland, and is maintained by government. It contains a large collection of plants, an extensive range of houses, including a palm house, and a museum of economic botany. The professor of botany in the university lectures in the class-room at the garden during the summer months.

The Royal Observatory, presided over by the Astronomer Royal for Scotland, who also holds the conjoint office of professor of practical astronomy in the university, is situated on the Calton Hill, in N. Lat. 55° 57′ 23·2″, and W. Long. 0^h 12^m $43{\cdot}0^s$ of time, or 3° 10′ 45″ of space, of the meridian of Greenwich. It is the property of government, who contribute an annual grant of L.100 toward its maintenance. Its principal objects are the provision of suitable instruments for the pursuit of the study of practical astronomy, and also to enable the Astronomer Royal to make those observations and calculations which are regularly published for comparison with those of sister observatories in this and foreign countries.

Besides his duties at the observatory, and the laborious reduction of a vast mass of important astronomical observations with the aid of a single assistant, the Astronomer Royal annually delivers regular courses of lectures on practical astronomy.

The Royal College of Surgeons.—The celebrity of Edinburgh as a place of education has been in some measure derived from the schools of a number of extramural lecturers of eminence in their several departments of science, particularly in medicine. These lecturers are chiefly members of the Royal College of Surgeons. This body, which was incorporated by charter in 1505, confers the same privileges on medical students as the University, that of doctor of medicine excepted. The College possesses a beautiful edifice in Nicolson Street, from a design by Playfair. Towards the street it is adorned with a lofty portico, which has a striking effect; and the details, though elaborate, are exquisitely finished, and in admirable harmony with the design. It cost the Royal College L.19,060, and forms several splendid halls for the accommodation of the members and the pathological museums. These museums, enriched by the collections of the late Dr Barclay and others, exhibit a valuable repository of preparations and objects calculated to advance the study of surgical science.

The Royal College of Physicians was established in 1681, by a charter of Charles II.; and the number of its fellows, resident and non-resident, is now about a hundred and sixty. The meetings of the body take place in the Physicians' Hall, a handsome edifice in Queen Street. It contains a good library, and very valuable museum of materia medica.

The New or Free-Church College was instituted in 1843, for the benefit of students qualifying themselves for the ministry. The session commences on first Tuesday of November and closes early in April. The classes consist of divinity, church history, Hebrew and Oriental languages, exegetical theology, apologetics, and pastoral theology, natural science, logic, and metaphysics. There are six professors, one of whom is principal. It forms one of the schemes of the Free Church of Scotland, and is supported by that body. The building, part of which forms the Free High Church, is plain but handsome, and was designed by W. H. Playfair. It stands at the head of the Mound.

The High School is one of the two chief seminaries in Edinburgh for classical education, and has long maintained an eminent place amongst similar establishments. Its origin may be traced to an early period in the sixteenth century; but it has been greatly extended and improved in recent times. The building now occupies a site on the south side of the Calton Hill, facing the road that sweeps round that eminence. The design was furnished by Thomas Hamilton, and the foundation-stone was laid on the 28th of July 1825. The main building extends about 270 feet in front, and in the centre of the edifice is a magnificent hexastyle Doric portico. On each side of the portico there is a corridor, the entablature of which is supported by six Doric columns. The apartments, which are entered through a spacious play-ground, consist of a large hall of 75 by 43 feet, and rooms for the accommodation of the various classes taught in the establishment. The cost of this extensive building was about L.30,000, which was partly raised by subscription. The patronage of the High School is vested in the town-council of the city. The curriculum of study extends over six years, and embraces the Latin, Greek, French, and German languages; history, geography, and the elements of natural science; with writing, arithmetic, algebra and geometry, drawing, fencing and gymnastics. Each class in the classical department is taught by the same master for the first four years, after which it passes into the charge of the rector. Connected with the school is a library of 7000 volumes, comprising many of the most important works in ancient and modern literature, to which the pupils have access. The vacation is during the months of August and September. The quarterly fees are:—Rector's class, L.1, 5s.; four junior classes, L.1, 1s.; writing and arithmetic, 7s. 6d. each; the other classes, 10s. 6d. each, attendance on the last seven branches being optional. The system of education is divided into two departments—Classical and English, and Commercial; and the whole is conducted by a rector and four classical masters, with teachers for the other branches. The usual number of pupils is from three to four hundred.

The Edinburgh Academy is a similar institution with the High School, but its fees are higher. It was begun a few years ago by a society with a capital of L.12,900, which may be augmented to L.16,000, raised by proprietary shares of L.50 each. The superintendence of the establishment is vested in fifteen directors, chosen by the proprietors from their own body. The system of education is nearly the same as that pursued in the High School. There are here also a rector, four classical masters, besides masters of modern languages and literature, mathematics, elocution, writing, fencing, and drawing. The complete course extends over seven years.

Besides the High School and Academy, there are a number of excellent private academies, many on very moderate scales of charges, and numerous free schools.

Free Schools.—The principal of these are the Heriot Foundation Schools, erected from the surplus revenues of Heriot's Hospital, in accordance with an act of parliament obtained in 1836, for educating within the royalty of the city free of expense poor children of burgesses and freemen deceased, or who are unable to provide for their support, or the children of poor citizens and inhabitants of Edinburgh residing within the royalty. There are twelve of these schools, eight for juveniles and four for infants, attended by about 3000 children; and this number is supposed, according to the census of 1851, to form about one-half of all the children belonging to the poorer classes within the royalty of the city of Edinburgh, from which alone the children are admissible. In the juvenile schools there are Sabbath-morning classes.

Dr Bell's Schools (two in number), under the patronage of the lord provost and magistrates and council, are also noted for the admirable way in which they are conducted.

Edinburgh. In each of them upwards of 300 children, who pay small fees, are instructed in English, grammar, etymology, geography, arithmetic, writing, the principles of the Christian religion, &c. There are attached to the schools eight apprentices, who receive fixed wages, and are indentured for assisting in the business of the school, and being trained as teachers.

Besides these, there are the Local Day Institution founded by Dr Andrew Thomson, the Canongate Burgh School, the Sessional School of Canongate, the Lancasterian School, the Apprentice Schools, and various others.

There are two Normal Schools, one in connection with the Established, and the other with the Free Church, and two Ragged or Industrial Schools.

The following table is taken from a parliamentary paper published in 1854, and, so far as it may be relied on, gives a brief view of the state of education in the city. It is, however, explained in that paper, that, in large towns especially, some schools have been overlooked, which is clearly the case in regard to Edinburgh, particularly as regards private schools not denominational:—

Denomination.	Number of Schools.	Number of Teachers.	Number of Scholars.	Number Educated gratuitously.	Income of Teachers.
Established Church...	20	61	3,271	841	£2,372 15 0
Free Church............	22	98	3.918	176	3,367 5 3
United Presbyterian..	10	17	1,293	159	609 10 0
Scottish Episcopal.....	5	13	919	177	465 0 0
Roman Catholic........	4	33	970	500	739 0 0
No Denomination......	31	183	6,743	3,299	13,661 16 8
	92	405	17,114	5,152	£21,215 6 11

Heriot's Hospital.—The founder, George Heriot, was born in the parish of Gladsmuir, and in the year 1597 he was appointed goldsmith and jeweller to James VI. He died in London (whither he had removed on the accession of James to the English throne) on the 12th of February 1624, leaving a fortune, it is supposed, of not less than L.50,000. Of this sum L.23,625, 10s. 3½d. were, by his bequest, appropriated to the founding and endowing of the hospital which bears his name, for the maintenance and education of children, the sons of burgesses of the city "who are not able to maintain them." The magistrates, town-council, and ministers of the town, were nominated the governors; and certain trustees were appointed to superintend the execution of the will. The building of the hospital was begun in 1628, and, after some interruptions, completed in 1650, at an expense altogether of L.30,000. It was not however opened for its legitimate purpose till 1659, when 30 boys only were admitted. There are now 180 in the establishment, all of whom are comfortably lodged, fed, and clothed; and all pains are bestowed upon their education, which comprehends Greek, Latin, English, writing, arithmetic, book-keeping, mathematics, and geography. On leaving the hospital they are furnished with a liberal supply of articles of dress of their own choosing; and such of them as are apprenticed to trades receive an apprentice fee of L.50, besides an allowance of clothing at the expiration of their indentures. Boys who distinguish themselves by their literary attainments, and who are qualified to enter the university with a view to the learned professions, receive bursaries of L.30 per annum for four years. Ten other bursaries of L.20 each, for the same period, are bestowed upon young men unconnected with the hospital who give proofs of superior talents. Boys are not admitted under seven years of age, and generally leave it at fourteen. As already mentioned under that head, the Free Schools in connection with this hospital form now a most important branch of its operations.

The hospital is situated in the southern part of the town, and is one of the most remarkable buildings connected with the city. It is three stories in height in the central parts, and four stories at the corners, with an interior quadrangle or court. It has been traditionally said to have been designed by Inigo Jones, and though no direct evidence can be produced for this, yet it seems highly probable. The character of the architecture is supposed to be an improvement on the common turreted Scottish style of the day; and the names of two Scotsmen have been brought forward, William Wallace and William Aytoun, both at different times called "master masons" of the work, to one or other of whom the design has also been supposed to be due. In 1832–33 this beautiful structure received some external repairs, and a lodge, which is a miniature of the hospital, was erected at the principal entrance.

Donaldson's Hospital was founded by James Donaldson of Broughton Hall, a printer in Edinburgh, who died in 1830, and bequeathed by his will, dated 4th July 1828, the greater part of his property, amounting to nearly L.200,000, to certain trustees for the endowment and erection of an hospital for the maintenance of poor boys and girls after the plan of the Orphan Hospital and John Watson's Institution. Poor children of the name of Donaldson or Marshall have a preference. The management is vested in trustees appointed in conformity with the deed of constitution. The building, commenced in 1842 and finished in 1850, is a structure of large dimensions, exceeding those of any building in the city excepting the university. The length of its south or principal front is 270 feet, and its depth (exclusive of the chapel which projects 90 feet from the north front) is 260 feet. The size of the quadrangle within is 175 × 163 feet, being greater than the external dimensions of Heriot's Hospital, which is 160 feet square. The style of architecture employed in the design is that which arose in Britain in the sixteenth century, when, upon mediæval architecture (which had been verging from ecclesiastical into civic and domestic application) were engrafted many features of modern Italian buildings; resulting in combinations which assumed a marked and individual style, eminently expressive of a high condition of social refinement and grandeur. On the centre of the south front a tower 49 feet square, with lofty central oriel corbelled above the entrance doorway, and with bold enriched cornices, embattled parapets, and perforated chimney-shafts, rises to the height of 120 feet; at each angle of which are attached octagonal towers pierced with mullioned windows, enriched with multiplied panellings, armorial bearings, devices and ornaments, and finished with ogee leaded roofs surmounted by richly carved stone lanterns and finials The four corners of the building have each a tower 43 feet square, and 92 feet high, with attached square towers terminated by lead roofs and finials, the main tower having oriels, battlements, and chimney-shafts. These corner towers are connected with each other and with the large central tower of the south front by intermediate stretches of building, having mullioned and labelled windows and buttresses surmounted by little curved pediments with angels' heads and terminal ornaments, the whole being crowned by a corbelled cornice and parapet with shields and devices, and terminal shafts above each buttress. The chapel, projecting to the north, partakes of the same general character of detail which obtains throughout the main building, but resumes somewhat of an ecclesiastical aspect by the introduction of archedm ullioned, and transomed windows, which, with a lintelled oriel to the north, serve to mark the idea of a domestic or baronial chapel. The interior, roofed with corbelled beams and panelling and having the walls lined all round with massive panelling and the windows filled with richly stained glass, sustains and enhances the effect of the exterior. The entire structure was designed and carried into execution by W. H. Playfair. It stands on a piece of ground about a mile to the westward of the city, on the line of the Edinburgh and Glasgow road.

Table showing the number of Hospitals in Edinburgh.

Name of Hospital.	For maintenance and education of	Age of admission.	Number admitted or maintained.	Fees on leaving.	Governors or Directors.	Date of Bequest.
Trinity.	Burgesses, their wives, or children not married, nor under 50 years of age.	Above 50.	108	... ...	Magistrates and Town-Council.	1567
Heriot's.	Sons of burgesses and freemen of Edinburgh.	7 to 10, leaving at 14.	180	Apprentice fee of L.50, according to circumstances, and allowance of clothes, or L.30 for 4 years for those who receive a college education.	Magistrates, Town-Council, and City Ministers.	1623
Merchant Maiden.	Daughters and granddaughters of merchant burgesses of city, or of ministers of city and suburbs, or of those who have been governors or benefactors to the hospital.	7 and under 11, leaving at 17.	100	L.9, 6s. 8d.	Five members of the Town-Council, master and 3 assistants of Merchant Company, 3 clergymen of city or suburbs, Earl of Mar, and 9 persons elected by the Merchant Company.	1695
Trades Maiden.	36 daughters and granddaughters of decayed craftsmen in Edinburgh, and the rest from any part of Scotland.	7 to 11, leaving at 17.	48	... ...	Convener of Trades, and deacons of 13 incorporations, 2 trades councillors, 2 persons of name of Erskine, president of Society of Barbers, and 9 persons elected by the other governors.	1704
George Watson's.	Sons and grandsons of decayed merchants, burgesses, or guild-brothers of Edinburgh, with a preference to the Merchant Company.	7 and under 10.	86	Apprentice fee L.10 for 5 years, and on attaining 25 years of age, if unmarried and able to show testimonials of good behaviour, a premium of L.50. Boys preferring a college education receive L.20 per annum for 6 years.	Master, 12 assistants of Merchant Company, 5 of the Town-Council, and minister of the Old Church.	1723
Orphan.	Boys and girls from any part of Scotland.	7 and not above 10.	100	... ...	Variable, and appointed by Trustees.	1727
John Watson's.	Destitute boys and girls.	5 and under 8, leaving at 14.	120	... ...	The Lord Clerk-Register and Depute-Keeper of the Signet, the treasurer of the fund, and 12 commissioners of the Writers to the Signet.	1759
Gillespie's.	Old men and women, and Poor boys.	55 and upwards. 6 to 12, and retained for 3 years.	40 } 200 }	... ...	Master, treasurer, and 12 assistants of Merchant Company, 5 of Town-Council, and ministers of Tolbooth and St Stephen.	1796
Donaldson's.	Poor boys and girls, especially of the names of Donaldson and Marshall, from any part of Scotland (of those already admitted a third are deaf and dumb).	6 to 9, leaving at 14.	300	Such sum of money or other assistance during apprenticeship or otherwise, as governors think advisable.	The Lord Justice-General, Lord Clerk-Register, Lord Advocate, Lord Provost, Lord-lieutenant of county, Principal of the University, senior minister of Established Church, Edinburgh, 2 ministers of St Cuthbert's Parish, preses of College of Physicians, treasurer and secretary of the Bank of Scotland, and 14 other gentlemen, 3 of whom go out annually by rotation, their successors being appointed by the remaining managers.	1828
Cauvin's.	Sons of poor teachers and farmers, whom failing, of printers, booksellers, or agricultural servants.	6 to 8, and retained for 6 years.	26	... ...	The Lord Provost, the Principal of the University and Professor of Humanity, Rector of High School, ministers of Duddingston, Libberton, and Newton, and others.	1825
Stewart's.	Poor sons of honest and industrious parents.	... ...	...	... ...	Trustees.	1814
Chalmers'.	Sick and hurt.	... ...	...	Building not yet erected.	Dean and Faculty of Advocates.	1836
Fettes'.	Young people whose parents have fallen into adverse circumstances.	... ...	...	Do. do.	Trustees.	1836

Edinburgh.

Commercial institutions.

Although not itself an extensive trading or commercial town, Edinburgh may be said to have contributed in an important degree to the vast progress which trade and commerce have made in Scotland, no less than in the other parts of the empire. By means of its banking institutions, capital has been diffused over every district of the country; and thus a beneficial influence has been exerted upon all branches of industry, commercial and agricultural.

Banks.—There are ten banks and branches of banks in Edinburgh, all joint-stock companies. Five are properly Edinburgh institutions, originating and having their principal establishments there. These possess an aggregate capital of L.5,600,000 sterling. Of the other five, two may be considered as partly Edinburgh and partly Glasgow establishments, having head offices and directors in both cities. These have each a capital of one million. The remaining three are branches of Glasgow banks.

The oldest bank in Edinburgh is the Bank of Scotland, which was established in 1695 by an act of the Scottish Parliament. The capital of the company was originally L.1,200,000 Scots (L.100,000 sterling), raised by shares of L.1000 Scots (L.83, 6s. 8d. sterling). This capital is now increased to one million sterling, and the shares have been converted into stock. The establishment is situated in Bank Street, near the head of the Earthen Mound.

The Royal Bank of Scotland was instituted in 1727 by royal charter. Its capital stock was originally L.111,000 sterling. This was raised in 1738 to L.151,000, and by various subsequent additions to two millions. The Royal Bank is in St Andrew Square.

The British Linen Company was erected into a bank in 1746, with a capital of L.100,000, which has now been raised to one million. This bank is also incorporated by royal charter. Its premises, lately rebuilt, are handsome and commodious; they are also in St Andrew Square.

The Commercial Bank of Scotland was established in 1810, and has a capital of L.600,000. It is incorporated, but its charter reserves the liability of its partners. It occupies a splendid new edifice in George Street, on the former site of the Physicians' Hall.

The National Bank of Scotland was instituted in 1825; capital one million. This bank is also incorporated, its charter containing a similar provision with that of the Commercial Bank. The bank is in St Andrew Square.

The other banks in Edinburgh are the Union Bank of Scotland, Parliament Square, an establishment which was originally the private banking-house of Sir William Forbes and Co., and joined the Union Bank in 1843; the Edinburgh and Glasgow Bank, George Street, established 1838; Branch of the Western Bank of Scotland (1832), St Andrew Square; Branch of the Clydesdale Bank (1838), Royal Exchange; and Branch of the City of Glasgow Bank (1839), Hanover Street.

There is also a National Security Savings Bank in Edinburgh, instituted in 1836. It occupies premises in North Bank Street.

The Merchants of Edinburgh form a body, called the Merchant Company, incorporated by a charter of Charles II. in 1681. This company is entrusted with the management of several charitable institutions, and is active in superintending measures connected with the commercial interests of the city. Its business is conducted by a master, treasurer, and twelve assistants, and their hall of meeting is a spacious apartment in Hunter Square.

Literature.—Edinburgh is distinguished as a mart of literature, and its inhabitants enjoy a reputation for cultivated tastes and habits. This character, however, is not of much older date than the latter part of the eighteenth century. Thirty years after Caxton had set up his press at Westminster, Walter Chapman and Andro Myllar, by a royal privilege of James IV., granted in 1507, established here the first printing-press in Scotland. From this only two publications are known to have issued;—one (in 1508), a collection of pamphlets, chiefly metrical romances and ballads, of which an imperfect copy is preserved in the Advocates' Library; and the other (in 1509 and 1510), the Scottish Service Book, including the Legends of the Scottish Saints, commonly called the Breviary of Aberdeen, in two volumes 8vo, printed in red and black letter, a copy of which is preserved in the University Library. The next work was published about the year 1506, and consisted of a black-letter folio volume, entitled "The History and Croniklis of Scotland, compilit and newly correckit be the Reuerend and Noble Clerke, Maister Hector Boece. Translatit laitly be Maister Johne Bellenden. Imprentit in Edinburgh be Thomas Davidson, dwelling fornent the Frere Wynd." The whole works of Sir David Lindsay were also printed by Davidson in 1540. Davidson was succeeded by Lekprevik, Vautrollier, Hart, Young, and others; but the press of Edinburgh did not become distinguished until the appearance of Thomas Ruddiman, the well-known philologist, born in 1674, and Allan Ramsay the poet, born in 1686. The numerous classical works which issued from the press under the editorship or authorship of Ruddiman were then models of typographical accuracy and beauty, while the general excellence of his Rudiments of the Latin tongue, which appeared in 1714 and is well known to every schoolboy in Scotland, is still acknowledged. The long practice he had acquired in superintending the press during the publication of his own works, induced him, in 1715, to establish a printing-press on his own account; and while proprietor of the Caledonian Mercury newspaper, he received the honourable appointment of librarian to the Faculty of Advocates.

Contemporaneously with Ruddiman, Allan Ramsay, the poet and bookseller, was engaged in the publication of several works of his own, among which the *Gentle Shepherd*, a pastoral comedy in the Scottish dialect, which appeared in 1735, then acquired and still retains great popularity. Previously to this, in 1721, Ruddiman had printed, in a handsome quarto volume, a collected edition of his minor poems and ballads, which Ramsay published in the succeeding year at the sign of the Mercury, opposite the head of Niddry's Wynd, and by which he is said to have realized four hundred guineas.

It was thus in the beginning of the eighteenth century that these two men first imparted to Edinburgh that literary character which it still enjoys, and which was the precursor of the era of a new system of publishing commencing with the establishment of the Edinburgh Review in the year 1802, and the publication of such large works as the early editions of the Encyclopædia Britannica. The person to whom Edinburgh is most indebted for an increase of its literary reputation is Sir Walter Scott, whose poetical productions appeared at intervals from 1802 till 1812, and whose novels and tales began to be published in 1814. The principal literary men whose names have generally been associated with Edinburgh, are David Hume (died 1776); Henry Home, Lord Kaimes (1782); Robert Henry (1790); David Dalrymple, Lord Hailes (1792); W. Robertson (1793); Hugh Blair (1800); John Home (1808); Adam Ferguson (1816); Malcolm Laing (1819); John Playfair (1819); Thomas Brown (1820); Dugald Stewart (1828); H. Mackenzie (1831); Sir John Leslie (1832); Sir James Mackintosh (1832); T. M'Crie (1835); Sir Charles Bell (1842); John Abercrombie (1844); Thomas Chalmers (1847); P. F. Tytler (1849); Francis Jeffrey (1850); D. M. Moir (1851); and John Wilson (1854).

The principal newspapers published in Edinburgh are the Scotsman, the Witness, Caledonian Mercury, Edinburgh Evening Courant, Edinburgh Advertiser, Scottish Press, and Evening Post, some of which are published

Edinburgh.

twice, and some thrice a-week. There are two weekly papers, the Guardian and the News; also a paper solely devoted to advertisements, and distributed gratis, on Saturday, called the North British Advertiser.

Civic institutions.

The Corporation.—The ancient civic establishment of Edinburgh was remodelled in 1833 by the act of parliament for reforming the royal burghs of Scotland. The management of the general municipal affairs within the royalty is vested in a town-council, consisting of thirty-one members chosen by the parliamentary electors of the five different wards, and renewed by one-third annually. To these are added one of the deacons of the ancient incorporated trades, elected annually as their convener by his brother deacons and trades' councillors, and the Dean of Guild elected by the guild brethren of the city. The council, thus composed of thirty-three members, elects out of their own number a chief magistrate, with the title of Lord Provost, and four bailies, who together form the magistracy of the city. Besides the ordinary powers of magistrates of royal burghs, the magistrates of Edinburgh are also, by virtue of ancient charters, sheriffs, coroners, and justices of peace, within the city and liberties, and possess and exercise all the powers, privileges, and jurisdictions competent to such officers. The city and liberties form a county of itself, and the Lord Provost is vested with the office of Lord Lieutenant. The magistrates are likewise admirals of Leith and the road thereof, but delegate their powers of holding admiralty courts to the magistrates of the burgh of Leith. The revenue of the Corporation of Edinburgh proper for the period from 2d August 1853 to 1st August 1854 was L.24,000, 14s. By the parliamentary reform act of 1832, Edinburgh and the adjoining districts and suburbs were formed into a parliamentary district, 9½ miles in circumference, which returns two members to parliament. The number of parliamentary electors on the roll in November 1854 was 7713, and the number within the municipal district 4229.

The Dean of Guild Court consists of the Dean of Guild (an office resembling that of the Roman Edile), and five guild councillors, with the dean of the previous year. The powers of this court were formerly far more extensive than they are at present, having relation to causes between merchant and mariner, as well as to those between merchant and merchant. The institution, however, of the Admiralty Court, by the act 1681, cap. 16, superseded its interference with maritime affairs. The Dean of Guild is chosen yearly, and with his council has power to regulate the buildings within the burgh, agreeably to law. He alone is competent to grant authority, by his warrants, or *jedges* as they are called, for pulling down or erecting houses within the burgh and liberties. The provost and bailies have no power to review the decrees of the Dean of Guild, redress being only competent in the Court of Session; as is the case also with the decisions of the bailie court. The public business connected with the civic establishment or corporation is conducted in the Royal Exchange Buildings. The public business of the county, and the sittings of the sheriff and justices, take place in the County Hall, adjacent to the Parliament House, and erected in 1819, at an expense of L.15,000.

The *superiority* of the Canongate jurisdiction, which formerly belonged to the abbot of Holyrood, was purchased by the town of Edinburgh from the Earl of Roxburghe, into whose hands it had fallen, in the year 1636. Since that period the burgh of Canongate has been governed by baron bailies appointed by the town-council from their own body, and by two resident bailies, also appointed by the same authority on the recommendation of the parliamentary electors. In a similar manner bailies are appointed to the subordinate districts of Easter and Wester Portsburgh.

Police.—Till the year 1805 the city was protected only by a feeble body of old men in the garb of soldiers, entitled the City Guard, which constituted the remains of a civic defensive force originally raised in 1514, after the battle of Flodden. In 1805 a regular police establishment was formed, and the city guard was finally dissolved in 1817. The police establishment was remodelled by specific acts of parliament in 1812, 1822, and 1832, and latterly in 1848 and 1854. The establishment consists of 32 general commissioners elected by the inhabitants of the same number of wards, qualified to vote by paying an annual rent of L.10. The body of general commissioners is increased by eight *ex officio* members, the lord provost, four bailies, the sheriff of the county, and his substitutes. Under this body there is an executive police, with a superintendent; and a criminal court is held daily on the plan of that at Bow Street in London. In it a town bailie officiates as magistrate or judge in all cases which occur within the ancient and extended royalty; whilst cases originating in that portion of the city included between the exterior limits of the royalty and the general police boundary fall under the cognizance of the sheriff. Edinburgh is now in all its parts well watched, lighted, and cleaned; and the expenditure for these purposes amounted in the year ending at Whitsunday 1854, to L.38,746, 1s. 5d. An assessment on the inhabitants, of about 1s. 2d. per pound on the rental, the produce of street manure, and the surplus of general fines, supply the revenue of the establishment. The head police-office is a large building in the High Street, with one of its sides to Parliament Square; and the number of the police force is 327.

Edinburgh Police Statistics for 1853.

Persons apprehended by the City Police and remitted to a *higher Court* consisting of the Sheriff and Bailies—285 males, 194 females, and 59 juveniles.

Persons *tried in the Police Court* for thefts, &c., 707 males, and 487 females. Of these there were under 14 years of age, 294 males and 33 females.

	Males.	Females.
Results of these trials:—		
Imprisoned (for periods under 60 days)	210	187
Whipped (males under 14 years of age)	140	
Ordered to find caution	66	40
Dismissed with an admonition	131	98
Fined	5	
Total number convicted	552	325
" " not proven	25	22
" " in which diet was deserted	130	140

Persons *tried in the Police Court for offences and contraventions, assaults, &c.*, 5401 males and 5443 females.

	Males.	Females.
Results of these trials:—		
Imprisoned	345	697
Whipped	43	
Fined	2504	1796
Ordered to find caution	528	577
Dismissed with an admonition	1579	2099
Total number convicted*	4999	5169
" " not proven	98	87
" " diet deserted	296	184
" " remitted as insane	8	3

* Of these there were for contravening cleaning regulations, 2159.

Prisons.—After the removal of the Old Tolbooth in the High Street, an extensive building situated on the Calton Hill, fronting the road which sweeps round that eminence, was provided for the city and county prison. The centre division of the range, called the prison of Edinburgh since the passing of the prison act for Scotland in 1839, was formerly the city bridewell, so called from having been built on the same principle as the St Brideswell prison in London. It was constructed in 1791, in the Panopticon form, after a plan by Robert Adam.

The west wing of the prison was erected in 1817, after a plan by Archibald Elliot—it was this part of the prison which was erected in lieu of the Old Tolbooth; and

Edinburgh. the east wing was erected in 1847, after a plan by Robert Brown. The buildings are in the castellated style of architecture, and have a fine appearance from whatever point they are viewed. The prison contains about 430 cells and rooms, and affords accommodation for both civil and criminal prisoners. The expenses of the establishment are defrayed chiefly by assessments, and partly by the labour of the inmates. A small lock-up-house adjoins the County Hall, and is used for prisoners under examination and before committal for trial. Since the passing of the present police act, prisoners remanded for further examination, and prisoners under sentence of three days' imprisonment from the police court, may be kept in the cells of the new police office in the High Street. The Canongate jail, an old-fashioned plain edifice of the time of James VI., and used for debtors, was discontinued as a prison after the erection of the east wing of the prison of Edinburgh in 1847.

The Poor.—Edinburgh, as regards poor-rates, is divided into three districts, the City parish (or ancient and extended royalty), the parish of St Cuthbert's, and the Canongate, each of which has a house for the reception of paupers, with distinct funds and a separate board of management. A portion of the eastern part of the city is in South Leith parish, for which there is no workhouse. The principal resource for the support of the poor is an assessment. The amount of money collected for this purpose in 1833 was L.13,479, 19s. 4d., whereas in 1814 it was only L.6943, 19s. 10d.

The following table shows the amount of accommodation available in the poor-houses of Edinburgh, and the number of inmates in each house on 1st of July, in each of the years 1850 to 1853, with the population of the parish, according to the census of 1851:—

Poor-houses.	Pop. 1851.	Accommodation.			Number of Inmates 1st July			
		1850.	1851.	1852.	1850.	1851.	1852.	1853.
Canongate of Edinburgh	10,801	163	163	160	107	121	117	100
Edinburgh City Parish	66,608	691	895	909	627	627	549	615
St Cuthbert's Parish......	82,479	686	691	661	554	551	599	619
Totals...	159,888	1540	1749	1730	1288	1299	1265	1334

In the city parishes of Edinburgh and St Cuthbert's, the orphans and deserted children that become chargeable, instead of being collected in the poor-house, are dispersed in the surrounding rural districts, where they are boarded in houses of the working-classes, and regularly visited by an assistant inspector appointed to that duty.

The income from the assessment (for 1853) was as follows:—

City parish	L.21,056	13	8
St Cuthbert's do....................	18,059	6	11½
Canongate do........................	2,946	4	3¾
	L.42,062	4	11¼

The average amount of cost of house inmates in the city parish poor-house for the last year was L.8, 10s., and for children at nurse L.7, 12s.

The number of permanent and outdoor poor and children at nurse, in 1853 was as follows:—

City parish, permanent........................	2000
Do. children at nurse...............	325
St Cuthbert's..	1776
Do. children at nurse...............	498
Canongate...	...
	4599

Besides these public institutions for the relief of the poor, there are numerous other charitable associations of a public and private nature.

Markets.—There are three market-days, Tuesday, Thursday, and Saturday, each week, for the sale of butcher-meat and vegetables; but on Wednesday only are held the markets for the sale of horses, cattle, sheep, corn, and other agricultural produce. The spacious street called the Grassmarket used to be the place where these Wednesday markets were held; but being found to be too small and inconvenient, a place for the cattle and sheep market was procured in the neighbourhood, and fitted up for the purpose in 1844, at the cost of L.8000. In 1849 a spacious corn-market was erected on the south side of the Grassmarket at the cost of L.17,500. It is a handsome building, with a front of three stories, in the Italian style, and a campanile or belfry at the west end. The covered market-place behind is 156 feet 6 in. in length by 97 feet in width, and is lighted from the roof. The butcher meat, fish, and vegetable markets are situate in the centre of the city, and consist of a series of descending open areas, connected by flights of steps from the back of the High Street to Market Street, below the North Bridge. They are well supplied with provisions; but a great part of the business formerly transacted in them is now carried on in private shops throughout the city. A public market for the sale of the same kind of provisions was erected about thirty years ago in Nicolson Street, a second in Old Broughton, and a third, on a large and expensive scale, costing upwards of L.20,000, at Stockbridge; but these speculations of private companies have proved almost complete failures. In 1852 an extensive range of slaughter-houses was erected by the town-council on an area of four acres purchased by them at Lochrin, in the south-west quarter of the city, at the cost of L.22,163; but they have been found already too small for the trade, and will require a speedy enlargement. These slaughter-houses and the corn market were erected from designs by David Cousin, architect, the city's superintendent of public works.

Edinburgh has the privilege of holding two yearly fairs, called the *Trinity* and the *Hallow* fairs; the former on the Monday after Trinity Sunday, and the latter in the first week of November, following the feast of All-Hallows, or All-Saints. The former, however, has long since fallen into disuse; but the latter is still held, and is a well-frequented market for the sale of cattle, horses, and sheep. It is held in such fields as can be hired for the purpose in the vicinity of the city. There is also a great market for sheep and lambs held on the first and second Mondays of April yearly, at the *House of Muir*, about 7 miles south of the city, the privilege of holding which was acquired by the magistrates and council from the Lord Abernethy of Saltoun in 1612.

Supply of Water.—Edinburgh seems to have been anciently supplied with water chiefly from wells within the burgh; but about the year 1680 a supply was brought in by a leaden pipe from the Tod's Well, on the estate of Comiston, a distance of four miles. An addition was subsequently procured from Bonaly; but the supply proving quite inadequate for the wants of the inhabitants, the town-council, being unable to raise money for the purpose themselves, surrendered their rights for L.30,000 to a water company, which was incorporated by act of parliament in 1819. This company expected to derive a sufficient supply of water from the Crawley spring, a feeder of the North Esk in Glencorse parish, and expended nearly L.200,000 in their works for bringing it into town. In the course of years this supply likewise proved utterly inadequate, and the company were forced at last, by public clamour, and the threatened rivalry of new companies, to take measures for increasing the supply. This they have effected by collecting the rain water that falls on the Pentland Hills into great ponds or reservoirs formed in the valleys of the Logan water, and the Bavelaw Burn; and their capital has been fixed by act of parliament (in 1853) at L.322,000. Still the supply is not overabundant, being only about 25 gallons a-day to each per-

Edinburgh.

son in the district supplied, which, besides the city of Edinburgh, includes likewise the towns and villages of Leith, Portobello, Newhaven, and Granton. The company are empowered to levy certain rates upon the rental of the city; but the maximum of their dividends is fixed at $6\frac{1}{4}$ per cent. per annum.

Gas-light.—Edinburgh is lighted with gas supplied by two companies, namely, the Edinburgh Gas-light Company, whose works are situated in the Canongate, and the Edinburgh and Leith Gas-light Company, whose works are situated in Leith.

Places of amusement, and pleasure-grounds.

The Theatre Royal was built in 1768, shortly after the commencement of the New Town, and acquired great reputation under the successive managements of Henry Siddons, and his brother-in-law W. H. Murray. Previously to this period the theatrical performances of the city were exhibited in the Canongate, where a play-house was erected in 1746, in opposition to a rival establishment in the Cowgate. The present house accommodates about 1500 people, and although externally of plain appearance, in internal arrangements it is neat and comfortable; and the company of actors has generally been considered as one of the best out of London. Recently during the winter months it has been used with much success for the representation of operas. It is situated at the east end of Princes Street. The Queen's Theatre and Opera-House has recently been erected on the site of the old Adelphi, at the head of Leith Walk.

The Assembly Rooms, George Street, where public assemblies, balls, and concerts, are held, are plain and unpretending in their external appearance, and were erected in 1787. The Music Hall, a recent addition to the original edifice, forms the largest of the apartments: it is seated for 1486, exclusive of the orchestra, which measures 108 feet long by 91 broad and accommodates 200 people. It contains a large organ, and is well adapted for concerts and public meetings. The ball-room is 92 feet long, 42 feet wide, and 40 feet high.

Princes Street Gardens.—Perhaps the most beautiful feature of Edinburgh in its modern state consists in the highly ornamental pleasure-grounds which occupy the open spaces between the Old and New Towns, as well as between the parallel ranges of Queen Street and Heriot Row. The low grounds to the east and west of the Earthen Mound continued for about fifty years after the commencement of the New Town in a very marshy and unprofitable condition. At length, in 1821, under the authority of an act of parliament, the ground on the west was drained, inclosed, laid out, planted, and highly beautified with walks, and has since been opened to the proprietors or tenants of property in Princes Street, or others, on payment of an annual fee. In 1832–33 the ground on the east was similarly inclosed; but having been recently purchased by the town, it has, under the superintendence of the city architect, been greatly improved and ornamented, and is now open to the public. Since the year 1820 the greater part of the ground north of Queen Street was inclosed and laid out in gardens or promenades in the same tasteful and pleasing style.

The Calton Hill (350 feet above the level of the sea) is the higher portion of one of those heights upon which part of the town is built, and forms one of the principal public parks or promenades. From its position, and the number of monuments with which it is covered, it confers great picturesque beauty on the town, and has been compared to the Acropolis of Athens. The principal access to it is from Waterloo Place, nearly opposite the prison, and convenient and well-made roads for pedestrians are carried over and around the hill in various directions, affording panoramic views of the town and surrounding country.

On the north are the lines of streets of the New Town, constructed of white sandstone, gradually extending with a moderate descent towards the flat ornamental grounds adjacent to the sea. Westwards we have the vista of Princes Street, nearly a mile in length; and on the opposite side of the Princes Street pleasure-grounds the huge unbroken line of tall structures forming the Old Town, terminated by the towers of the Castle. Towards the south the town is seen to spread out in lines of streets and detached houses, till arrested by the Braid and Pentland Hills, or on the east by Arthur's Seat and Salisbury Crags. The view from the Calton Hill in a northerly direction beyond the town is also remarkably fine, comprehending a prospect of the whole Firth of Forth and the hills of Fifeshire.

Arthur's Seat and the Queen's Park (surrounding Holyrood Palace) are now rendered additionally attractive by the formation of the Queen's Drive, an excellent road round the hill, made recently in the most perfect style by the Commissioners of Woods and Forests, and affording the finest views of Edinburgh and its neighbourhood. The hill itself is a noble object, presenting bold pieces of rocky scenery, the principal of which are Salisbury Crags and Samson's Ribs. The summit is 822 feet above the level of the sea.

The Meadows.—In the year 1722 a marshy ground, anciently called the Burrowloch Boroughmuir, in the southern environs of the city, was inclosed, drained, planted with trees, and traversed by extensive broad walks, for the accommodation of the citizens. These public grounds, which receive the appellation of the Meadows, and bear some resemblance to the Green Park in London, are bordered on the south-west side with extensive open downs, called Bruntsfield Links, which are also open to the public, and form a place of agreeable recreation for youth, as well as an excellent golfing ground.

Monuments.

The National Monument occupies a prominent situation on the Calton Hill. It was begun by a body of subscribers in 1822, and was intended to be an exact model of the Parthenon at Athens. Its object was to commemorate those Scotchmen who had fallen in the different engagements by sea and land during the wars consequent on the French revolution; but it has been arrested in its progress for want of funds, and only twelve massive pillars of exquisite workmanship have as yet been completed.

A monument of a singularly elegant description, designed by Mr Playfair, and which is a reproduction, with some variations, of the choragic monument of Lysicrates, was erected in 1830–31 on a prominent situation on the Calton Hill. It is commemorative of the late Dugald Stewart, professor of moral philosophy in the University of Edinburgh. A monumental erection, commemorative of Professor Playfair, is also placed on the Calton Hill, at the corner of the inclosure of the Royal Observatory; and more recently another to the memory of Robert Burns, from the street of the Tripods, has been raised on an isolated eminence fronting the new High School. David Hume's Monument, after the model of an ancient Roman tomb, stands within the old Calton Hill burying-ground.

Lord Melville's Monument, an elegant fluted column, in the centre of St Andrew Square, was finished in 1828. It was raised by subscriptions chiefly among gentlemen connected with the royal navy. On the summit is a colossal figure of the above nobleman, cut in freestone. This beautiful column rises to the height of 136 feet, is modelled after Trajan's pillar at Rome, but without the sculptures, and forms altogether a very prominent and striking object.

The monument to Sir Walter Scott is situated in the East Princes Street Garden, opposite the foot of St David Street. It was designed by George M. Kemp, a young man of humble condition, who died before the structure was completed. The foundation was laid in 1840, and the building completed in 1844, at a cost of L.15,650. A stair conducts to the top of the monument, which is 200 feet high. A marble statue of Scott by Steele, for which the sculptor received L.2000, is placed underneath the princi-

 pal arch, and several sculptural impersonations of characters portrayed in the writings of Sir Walter occupy some of the larger niches.

The equestrian statue of Charles II. (Parliament Square), in vigour of design and general effect, maintains its rank as one of the best specimens of metal statuary in the city. It was cast in Holland, and is composed of lead.

The fine equestrian statue of the Duke of Wellington, by Steele, occupies a prominent position in front of the Register Office. The statue is fully 13 feet in height, and contains about 12 tons of metal. The pedestal, of Aberdeen granite, is 12½ feet high. The different parts were connected by fusion—a novel operation, attended with considerable labour and difficulty. The ceremony of its inauguration took place in 1852. A statue of Burns, by Flaxman, is in the hall of the University Library. The equestrian statue of John Fourth Earl of Hopetoun, in bronze, stands in front of the Royal Bank, St Andrew Square. There are two statues of Queen Victoria; one, by Steele, on the top of the Royal Institution, and another in front of Holyrood Palace, by A. H. Ritchie. In George Street, at the crossing of Hanover Street, stands a pedestal surmounted by a bronze figure of George IV., erected in 1832, in commemoration of the visit of His Majesty to Scotland in 1822. A statue of Pitt, on a similar pedestal, was erected in George Street, at the crossing of Frederick Street, in 1833. Both statues are by Chantrey. There is a bronze statue of Frederick Duke of York on the Castle Hill; and a statue of Watt, in freestone, by Sclater, is placed in front of the School of Arts, Adam Square.

Population. In 1755, shortly before the commencement of the New Town, Edinburgh had a population amounting to 57,195; in 1775 it was computed at 70,430; and in 1791 it had risen to about 80,000. In 1801, by parliamentary census, the amount was 82,560; in 1811 it was 102,987; in 1821 it was 138,235; but in these latter enumerations the population of Leith was included.

Statistics of Population, extracted from Mr Thorburn's Analysis of the Census of 1851.

Increase.—The population, which between the census of 1831 and that of 1841 had been almost stationary, has during the last ten years received a very considerable augmentation. The increase is 10,477 or 18 per cent., while, taking the *Old Town* separately, the increase is 6467 or 27 per cent., demonstrating generally the prosperity of the city during the last ten years.

In the absence of extended commercial transactions and manufactures, which have caused such a large accession to the population of Glasgow, and in England to that of the metropolis, Liverpool, Manchester, and other manufacturing towns, the increase in the Old Town may perhaps be ascribed to the construction of the railways communicating with the city, which, since the date of the last census, had, in consideration of the high wages, induced many of the natives of Ireland to leave their own country and settle in Edinburgh. Again, by the operation of the acts for extending the royalty, Leith Street Terrace, the greater part of Leith Street, part of East Register Street, East Broughton Place, and part of Broughton Place, containing collectively a population of about 1200 persons, have, since the census of 1841, been disjoined from St Cuthbert's Parish, and annexed to the extended royalty. Another cause has tended in some degree to augment the population. The census, which in 1851 was taken on the 30th of March, was in 1841 taken on the 6th June, at which time considerable numbers of the population generally retire to the country. Against these "accidental" causes of increase must be placed the dislodgment of the population residing in Canal Street and its immediate neighbourhood, removed since 1841 to make room for the various railway stations.

Old Church Parish is pre-eminent in the department of "Increase." That of the males amounts to 50 per cent. The females show an increase of 32 per cent.: the average of both sexes is 44 per cent. Features of parishes.

[1] For the information of such as may not be resident in Edinburgh, it may be proper to state, that "City," "Royal Burgh," and "Ancient and Extended Royalty," are synonymous terms. "Old Town" and "New Town," again, correspond with "Ancient Royalty" and "Extended Royalty," respectively.

St Mary's Parish exhibits strikingly the disparity of the sexes, which forms so remarkable a feature in the New Town; while the male population numbers 2854, the females amount to 5029, or nearly double. If we exclude the juvenile portion of the population, the results are still more extraordinary; for, while the male population above 15 years of age amounts to 1804, the females of the same class are 3970—being considerably more than double the male population. The solution of this remarkable fact is to be found in the number of female servants in this parish. Of these there are 2254 above 15 years of age—a number considerably above half of the entire adult female population.

Rental.—The gross amount of the rental of dwelling-houses, shops, warehouses, &c., producing above five pounds of rent, within the bounds of police, for the year ending at Whitsunday 1833, was L.406,484. In the year 1853 this sum had risen to L.479,051, and in 1854 to L.484,563.

EDINBURGHSHIRE, or, as it is often called, MID-LOTHIAN, is the seat of the metropolis of Scotland. It is situated between N. Lat., 55. 39. and 50. 59., and Long. W. of Greenwich, 2. 36. and 3. 33. Its boundaries are the Firth of Forth on the N., Linlithgowshire or West-Lothian on the N.W., Lanarkshire S.W., Peebles and Selkirkshire on the S., and Roxburgh, Berwick, and Haddington shires on the E. In form it is very irregular, being narrowest to the Forth, and spreading out towards Lanark and Roxburgh shires. The area comprises 360 square miles, or 230,400 acres; whereof 99,275 acres are under regular cultivation, 26,657½ acres permanent pasture, 831¾ irrigated meadow, 4177¾ called waste, 7321¼ in wood; the remaining area is occupied by towns, villages, sheep-walks, roads, &c.

The surface of this county presents a great variety of scenery. Within the space of a few miles the stately grandeur of the metropolis, the trim elegance of the suburban villa, and the desolate loneliness of a highland glen may be seen. Bounded by the Firth of Forth from Musselburgh to Cramond, the land everywhere rises towards the base of the Pentland Hills, which advance boldly from the S.W. to within five miles of the sea at their eastern extremity. S. and E. of these hills the surface is flat but broken, and again rises to the Lammermoors, the mountains at the head of the Gala, and the Moorfoot-hills. Of the low districts comparatively a small portion is flat. The occasional outbursts of trap, and frequent undulations, diversify its surface, while the woods surrounding the residences of the proprietors beautify and enrich a scene possessing much natural grandeur and loveliness. One cannot travel along a mile or two of road, but some eminence brings into view the ever-changing sea, with the Lomonds, Ochil Hills, and the Grampian Mountains in the distance; while Arthur Seat, the Castle Rock, the Braid, Craiglockhart, and Corstorphine Hills, and the more lofty sweeps of the Pentlands, contrast finely with the rich and beautiful plains around.

Many memorials of the ancient inhabitants of this district have been found, or may still be seen. At Cramond various objects of Roman art have been got; and it is believed that that place was once their principal seaport on the east of Scotland. Along the banks of the Almond, which falls into the sea there, and upwards to where it passes into West-Lothian in Livingston parish, numerous burial places have been discovered; the chief of which is at Old Liston, having the form of a circular mound rising in the centre of a flat field, in the middle of which field stand three large upright stones, like giant guards over the ashes of the dead. Not far off there is another rough pillar; while at the Briggs farm stands the "Cat-Stane," with a Roman inscription upon it. In Ratho parish there is also an upright pillar and an altar stone. Above Comiston and near Morton, a similar upright stone exists, while more of these Standing Stones, as they are called, described in the local traditions as the battle-stones of the Picts, are seen in other situations. On various heights, such as Dalmahoy Hill, are shown what are said to have been the camps of the invaders at the time when the bow and the sling formed the arms of the warriors.

On the North Esk several traces of the early people who dwelt there also exist, but the valley of that stream is more enriched with the remains of a more advanced period of history; of which the chapel of Roslin, founded by the St Clairs in 1446, and Hawthornden, the seat of the poet Drummond, attract many to its banks. Further south Borthwick and Crichton Castles stand as records of the age before gunpowder was known. Dalhousie Castle and Dalkeith Palace keep up the connection between the past and the present, which Craigmillar, associated with the name of Mary Queen of Scots, has long ceased to do. Merchiston Castle, where dwelt Napier the inventor of logarithms, is seen to the S. of the city; while many a modern pile has since been raised between Whitehill and Barnton. On the S.E. brow of the Pentlands, at a place called Rullion Green, the Covenanters gave battle to the king's troops.

Of the several streams rising in the hilly ranges, the Gala flows southwards to the Tweed—in the district which bears its name. The Tyne, rising above Crichton, runs N.E. into Haddingtonshire. There is also the Esk, whereof the southern branch flows from the Moorfoot Hills, the northern from the southern slopes of the Pentlands. The Water of Leith also rises in the north-western side of the same hills. The Almond rises in Lanarkshire, and forms the boundary between West-Lothian for a considerable space. Rising in an elevated district, the course of these streams, though short, affords a large amount of water-power, considering their volume. The only loch of any extent is that at Duddingstone, near Edinburgh. The Edinburgh Water Company have constructed several large reservoirs—the first, called the Compensation Pond, between two hills at Logan House; and several others on the northern side of the Pentlands, at Bonaly and Bavelaw; while the reservoir for the supply of the Union Canal at Cobbinshaw covers several hundred acres.

The natural history of the county affords a wide field for interesting investigation. Hutton first brought the rocks into notice; and since then the fossil fishes in Burdiehouse lime-quarries, and the fossil trees at Craigleith, are conspicuous. Of the various rocks which are found, none can surpass the Craigleith freestone for building purposes; and a vast excavation has been made for the supply of this material for the city. The cost both of quarrying and hewing the rock has caused recourse to be had to cheaper substitutes; and from Redhall and Hailes much stone is taken. This last forms coarse pavement and excellent steps for stairs, and is largely wrought. Many valuable greenstone or whinstone quarries exist: that at Barnton Mount supplies blocks of large size, which have been sent to England for docks, and even to Russia for fortifications. The causeway stones for the streets of Edinburgh are now procured from the whin quarries at Ratho, whence they are conveyed by the Union Canal. Materials of this sort for roads abound in every quarter.

Coal occupies two situations. The extensive deposits in the basin lying between the Pentlands, Inveresk, and Crichton, is the source from which a large supply is taken to the city. As many as 33 seams are enumerated, of various thickness and quality, including gas as well as household coal. The history of the working of these various seams, and its results on the fortunes of their proprietors, or those interested in them, has been of a very chequered nature; large sums having been lost in a fruitless search, or in too sanguine expectations as to the richness of the beds to be reached. Along the northern side of the Pentlands,

from the city to the western extremity, a distance of 18 miles, no coal is wrought; but close on the borders of West Lothian, at Muirhouse-dykes, Wood-Muir, and Longford, a supply is procured for the wants of the district.

Limestone is of frequent occurrence, and is wrought in many situations where coal is not to be had: at Esperston in the south; at Cousland, Crichton, Burdiehouse, and Gilmerton, near Edinburgh; at the Camps in Kirknewton parish; at Muireston and Levenseat still further west. Less is now used for agricultural purposes than formerly, but for smelting iron a large supply is quarried.

Although no blast furnaces have been erected in this county, nor any of those large works which have changed cold barren moorlands into populous districts, and added so largely to the wealth of the country, still ironstone has been wrought for a long period; first to supply the Wilsonton works, and more lately, and now at Muldron in West Calder parish, for the Shotts Company.

Numerous beds of clays are found, and when tile-draining became so prevalent about 1835, many works were erected. The demand having fallen off, they now only are found where a good local demand, fine clay, and plenty of coal are combined; or at Portobello with a large brick trade; at which place and at Edmonstone, fire-clay also is manufactured into the various articles for which it is now used.

To paper-works and corn-mills the water-power of the district is chiefly applied. The quantity of paper made on the Esk and Water of Leith is very great: the process of manufacture is curious and interesting, and forms a striking criterion of the progress of art and civilization. Large quantities of flour are made, and also pot-barley; while much of the oatmeal, which forms the food of the manufacturing districts, is made here. The art of milling is here thoroughly understood, and the article commands the highest price in the market. There are fewer distilleries than formerly. There are carpet-works at Lasswade, gunpowder mills at Stobbs and Roslin, iron-works at Cramond, potteries and salt-pans in Inveresk parish, sailcloth-yarn mills at Balerno.

The climate varies exceedingly; along the low flat eastern portion less rain falls than westwards, while the air is drier. At Inveresk, 90 feet above the sea level, during seven years ending 1853, the average fall was 24·8 inches. In Ratho parish, at 350 feet, 28·8 inches was the fall during the same period. In the earlier editions of this work 25·75 inches is stated as the average fall for the eight years ending 1792 near Edinburgh, and 46°·57 was the mean temperature. At the sea level at Leith 48°·36 is the recent average, while at Bonaly, 1100 feet above the sea, 44°·21 is found to be the mean.

The prevailing winds are from the south-west, north, and north-east. This last, save on the coast side, never rises so high as the south-west, but its effects are far more pernicious on men and animals. In few other counties is the effect of altitude so distinctly traceable, or so sudden. On the shores of the Firth, up the Almond and Esk, and in several of the rich flats, the grain crops ripen fully earlier than in most counties; while a couple of miles nearer the hills, and 200 feet higher, the harvest is ten days later; and still further up at an elevation of 600 feet, another week at least intervenes; and in some spots the crops are as late as any in Scotland. It has often been a subject of remark that the *fiars* prices of grain for a county so placed as this is are lower than others not so favourably situated. The cause is the variety of climate. So long has this been known, that from time immemorial, in fixing these prices, it has been the practice to divide the county into three districts, the Low, the Middle, and the High, examine from each an equal number of witnesses, strike the average from their sales, and take that as the *fiars* price. As the agriculture of these districts is very dissimilar, we can follow no better division than that referred to.

The low district extends from the coast-side inwards by Dalkeith, Slateford, and Ratho. Here are grown those crops which supply the wants of the city. Potatoes, turnip, clover grass, hay, straw, are all carried there, as well as grain; manure is brought back; and cattle are either reared or fattened. Several dairies send milk fresh to town, and their number is increasing. A few fields are pastured, but in general the only grass land is around the houses of the landlords. The farms contain from 50 to 400 acres, and are let on 19 years' leases at rents from L.3 to L.6 per acre, one-half of which is payable at Candlemas, the other at Whitsunday or Lammas, in the year succeeding that on which the crop is grown; and which usually varies with the price of grain. The labour is performed by married men who live in cottages on the farm. Three are required for each 100 acres, and one horse for every 20 or 30 acres, according to situation. Women and boys, some of whom come from the city, do the barn work, weeding and cleaning, and other light labour. The harvest work is chiefly performed by Irish reapers, and some few scythemen. Reaping machines have also been tried, but the heavy tangled crops are too much for them. The land for potatoes is either manured in autumn, or in the drill when planting. From 24 to 34 tons is allowed of horse and cow dung per acre. When the lesser quantity is given, guano also at the rate of from 2 to 6 cwt. accompanies it. But guano is no favourite so near the city. The time of planting is March and April; seed per acre, 10 cwt.· produce, 5 to 8 tons. Wheat succeeds, and is sown in November, either broadcast or in drill. Hunter's and Fenton's are the kinds mostly sown; but Spalding's and Talavera are also grown. Either barley or turnips succeed the wheat. If barley, it has 15 tons of dung ploughed in autumn, or an equivalent of guano in spring, to be followed by turnip. The turnips in either case receive rather less manure than the potatoes, and are all carted off the ground; being sold to cowfeeders, who pay from L.12 to L.20 per acre for them. Barley or spring wheat again succeeds, to be followed by clover grass, which is sold green. Oats follow again, to be succeeded by potatoes or beans. The grain grown in this district is of the finest quality, and commands the highest price for seed corn, for which there is a considerable demand. A small part of this district is naturally dry, and the soil over the whole has been much altered with repeated heavy manurings, and it is now mostly of a free open texture, the heavy clayey portion having become so. Elkington's system of draining was early introduced, and tile-draining more recently has been extensively followed, first at two feet deep, and of late at four, and from 18 to 36 feet apart. Steam-engines for thrashing the crops have been in use since 1830. They are non-condensing, and from four to ten horse power. Fences are chiefly thorn hedges; but stone walls surround the pleasure-grounds of the gentry. The capital required for farming purposes amounts to about L.10 per acre.

The farm buildings are not extensive. They are either slated or tiled. Improvements have taken place in the new cottages, but there is still much to be done in this respect. The *bothy* system is unknown here. The ploughmen are a steady, regular class, hired by the year, partly in money, and partly in meal and potatoes,—the wages for 1854 being about 12s. 6d. per week, the various items being calculated at fiars prices.

There are about 200 acres of irrigated meadows, east and west of the city. Those to the west, from the liquid not being so rich, have never produced such large quantities of grass as those eastwards, where the most of them lie. The old meadows at Lochend Farm extended only to 15 acres; but a large increase has taken place between these and the sea, wherever the water could be raised, either by levels or steam power; and a large barren waste on the sea-coast between Portobello and Leith, now carries luxuriant crops of grass. From four to five cuttings are

yearly obtained. Each acre lets for the season at from L.15 to L.35. The grass is entirely consumed by cows (it having valuable milk-producing properties), and, along with brewers' grains, forms their summer food. Of all the present applications of sewerage-manure water, that by gravitation forms the most profitable; and when it can be applied without detriment to the health of the inhabitants, it is certainly very deserving of being so, for it supplies a large quantity of milk-producing food, in close proximity to the place where it is most required.

The nursery grounds are very extensive, and supply a variety and quantity of plants, shrubs, and forest trees, equal to any in Britain.

In one parish in the vicinity of the town the average produce of wheat per acre for the four years ending 1854 has been estimated at 48 bushels, barley $57\frac{1}{2}$ do., oats $64\frac{1}{2}$ do., turnips 24 tons, potatoes $7\frac{4}{20}$ tons per acre; which may be compared with a similar estimate from a high parish of $25\frac{3}{8}$ bushels wheat, $25\frac{5}{8}$ barley, $20\frac{4}{8}$ oats, $11\frac{4}{20}$ tons turnip, and $2\frac{8}{20}$ tons potatoes: showing the increase which high cultivation, plenty of manure, and fine climate, confers on a soil originally not of the finest quality.

The middle district comprehends the space lying beyond the forementioned line, but does not approach to the hill sides or moorland tract. It covers a larger space than the former, and the same system of farming prevails as in the most improved counties removed from cities. Few potatoes are grown, and turnips are all consumed on the farm with the straw. Save where railways pass, distance prevents town manure being carted; but the canal towards the west takes off a considerable quantity. The rents range between L.1, 10s. and L.3 per acre. The farms are larger, fewer hands are employed, and also fewer horses kept. The crops are not so large, nor the quality of grain so fine. Guano is largely used, in conjunction with farmyard dung. The farm offices are commodious, but in many cases old. The rearing and feeding of cattle is here practised. Byres, boxes, and yards, are all in use. Save the harvest labourers, all the people reside on the farm. Draining with tiles and small stones began about 1830, and was very generally practised, the distance apart of the drains being about 36 feet. Since 1845 deeper drains have been put into the intermediate furrows, with pipes and collars. There are considerably more dairy farms here. A large portion of land is pasture, the best part of which is grazed with sheep, which are sold fat. The soil varies from the free open soil lying on trap, to the stiff, heavyish clays. Most of it is of an intermediate quality; and the system of fallowing having given place to turnip husbandry, in texture it has become much more free, and on part of it the turnips are eaten off with sheep. The cattle fed are chiefly bought for that purpose: they were formerly all of the Angus or Aberdeen horned breeds, but now they are either Irish or English one and two year olds. From the quantity of stock kept, fully L.10 per acre is required as capital, as the high farming system increases the amount of capital required. The leases here are also for nineteen years, and, as a rule, the old tenants have always the first offer of their farms before the expiry of the existing contracts. Many of the properties being of moderate size, the proprietors are as often changed as the tenants. On one estate we know, which has been held by eight different owners during the last fifty years, a tenant has continued o hold the same farm under all of them.

The high district includes all the moorland tracts and hill-sides where corn is grown. As it reaches an elevation of more than 800 feet, almost no wheat is grown, and oats are the chief corn crop. To the S.E. sheep are reared and fed, while to the W. the dairy is most common—indeed, on every farm from 10 to 40 cows are kept. The milk is churned, and butter and milk carted to the city, often 16 or 18 miles: brewers' grains or distillers' refuse being taken back in return. The cows are partly bred on the farm, and are of the Ayrshire breed, or crosses between it and the short-horn. The churns are wrought with horse-power. The rents vary between 15s. and L.2 per acre. The farms are often larger than in the other districts, but of course less valuable. Improvements have proceeded somewhat slowly here; and there is still a large portion of land to drain, which is now being done with drains $3\frac{1}{2}$ or 4 feet deep.

The accommodation both for the tenants, their labourers, and cattle, is somewhat poor. A large space is occupied with the Pentlands, Moorfoot, and other hills; on these both Cheviot and blackfaced sheep are grazed. This last breed predominates on the higher heathy hills, while the Cheviots occupy the lower greener heights. On each holding there are from 30 to 80 scores kept; one shepherd attends to upwards of 30 scores. Lowland farmers hold many of these farms, and are non-resident. Improvements have been going on here also. Many years ago what were called sheep drains were cut; in several places these are giving place to deeper drains, fitted with pipe and collar. Among the hills bordering on the Gala, where the subsoil is dry, guano has been extensively used for raising turnips. These are eaten off with sheep, and a crop of barley raised, or they are at once sown for pasture, by which means the herbage has been doubled. Very great improvements have been effected on many farms along the Gala by inclosures, since the railway passed through that district.

There are two weekly grain markets held in the county —in Edinburgh on Wednesday, and Dalkeith on Thursday. The latter, since the railways have been opened, has fallen from the position it was wont to hold, of the first in Scotland,—Edinburgh now taking that place. There were sold in that market in 1854 of

	Quarters.
Wheat	41,764
Barley	50,967
Oats	47,705
Beans	5,596

Of course, these quantities do not include the whole sales, but only those passing through the market books. The grain is either brought in by carts or by railway, and is paid for immediately after the sale.

There is also a weekly sheep and cattle market on Wednesday, when from 3000 to 6000 sheep, and from 600 to 1000 cattle are offered for sale. On the second Tuesday of November Hallow Fair is held, when from 10,000 to 15,000 cattle are exhibited, and a horse market thereafter. There is a sheep fair also on the first Monday in April for lambing ewes at House of Muir, with a show of about 10,000 head of stock. A cattle and horse fair is held in October in Dalkeith; and two hiring fairs at Mid-Calder, where both cattle and horses are exposed for sale in March and October.

The valuation of Edinburghshire taken in 1649 is L.191,054, 3s. 9d. Scots. In 1811 the real rental of houses and lands, according to the property-tax, was L.677,832, 4s. 7d. In 1849, from the prisons assessment, L.1,389,111 was the valuation; and in 1855, at the previous rate of increase, it will reach one and a half millions sterling. In the county there are 30 parishes, with part of Fala and Kirkliston. Five parishes are included in Edinburgh and Leith, with a population in all, by the census of 1851, of 259,493, including Fala, but not part of Kirkliston. Excluding both of these and the five city parishes, the 25 landward ones contained 64,493 in 1851, all of which are now assessed for the poor, on whom L.15,902, 6s. $8\frac{3}{4}$d. was expended in 1853. A police force also exists in the county, with a superintendent, assistants, and 22 district officers.

Portobello and Granton, since the opening of the railways, may be said to form part of the metropolis. Dalkeith is the largest landward town, or burgh of barony

Musselburgh, Lasswade, Gilmerton, Loanhead, Cramond, Corstorphine, Mid-Calder, Ratho, and Currie, do not exceed the size of large villages.

The Union Canal, which was opened in 1822, runs for 10 miles through the county, and conveys stones, coal, &c., to the city, and manure from it, but no passengers or goods. The Dalkeith Railway was laid in 1836, but merely as a horse-way. Since then the Edinburgh and Glasgow Railway has been constructed, passing through the county for about 10 miles; the Caledonian for 18; the North British, in its various lines, for fully 30 miles; and the Edinburgh, Perth, and Dundee, to Granton and Leith.

There are in the county 423 miles of turnpike roads, from which L.22,210 was collected in 1850 from the five district trusts. The traffic on the various roads has now greatly changed, the most of it consisting of short journeys to the railway stations; and several of the finest roads, such as the one to Queensferry, are now in little use.

There are ten noblemen holding property in the county, the most of whom have residences in it; also nine baronets, and ten families who have held their estates for a very long period. The rest of the land in the county has frequently changed owners.

Edinburghshire sends four members to parliament; two from the city; one from Leith, Portobello, and Musselburgh; and one from the county, the constituency of which amounted to 2133 in 1854.

Agricultural Statistics of the County Crop 1854.

(Total number of imperial acres returned 211,147½.)

Number of acres imperial in tillage.

Wheat	8,128
Barley	11,212¼
Oats	22,852
Bere	50¼
Beans	1,551
Pease	185¼
Vetches	1,080¼
Turnips	14,288½
Potatoes	5,518½
Mangold	77
Carrots	62
Cabbages	89¼
Flax	16
Turnip seed	155
Bare fallow	635¾

Number of acres in grass, roads, and woods.

Grass in rotation of farm	33,373½
Permanent pasture	26,657½
Irrigated meadows	831¾
Sheep walks	69,284¾
Houses, roads, fences	3,598¾
Waste	4,177¾
Woods	7,321¾

Average produce per imperial acre of following crops.

	Bushels.	Pecks.
Wheat	32	1
Barley	40	2
Oats	38	0
Bere or bigg	31	2
Beans	31	1
	Tons.	Cwts.
Turnips	17	4
Potatoes	4	15

Gross produce of following crops.

	Bushels.
Wheat	262,128
Barley	454,116
Oats	868,376
Bere or bigg	1,582
Beans	48,468
	Tons.
Turnips	245,762
Potatoes	26,212

Total number of stock kept, 1854.

Horses	4,582
Milk cows	5,430
Other cattle	7,784
Calves	2,540
Ewes, gimmers, ewe hogs	83,395
Tups, wethers, wether hogs	26,148
Swine	6,403

The above returns are taken from the report furnished to the Board of Trade by the Highland Society. The entire extent of the county is not accounted for, as many of the hill farmers do not know the number of acres they hold. The produce of wheat, as given, may be considered about two bushels per acre above an average, and that of oats and barley slightly above it. The number of farmers is said by the last census (1851) to amount to 534.

EDMONTON, a village in the county of Middlesex, 8 miles north of London, on the London and Cambridge railway. It has an ancient parish church and numerous villas. This is the place referred to in Cowper's humorous poem of John Gilpin.

EDOM. See Idumæa.

EDRISI, or Aldrisi, the most eminent of the geographers who have written in the Arabic language. There is no individual of equal eminence over whose life there hangs a deeper veil of mystery, the various parts of it affording rather subjects of controversy to the learned than of precise information to the biographer. The place, and even the country in which he was born, compose the first subject of disputation. Sionita and Hezronita, who published a Latin translation of his work at Paris, make him a Nubian, and gave to their work the title of *Geographia Nubiensis*, the Nubian Geography. They proceeded upon the expression there used, namely, "the Nile of Egypt, which cuts *our* land." Hartmann was at once led to suspect the correctness of this inference, by observing that Nubia was one of the countries of which Edrisi gives the most meagre and imperfect account; and his suspicions were confirmed by learning that Ockley, on examining two manuscripts in the Bodleian Library, had found in both "that land," instead of "*our* land." It seems now generally agreed, therefore, that there is no reason to suppose him of Nubian origin. Others have assigned him an Egyptian one, which seems more probable, yet rests solely upon the erroneous reading above referred to. In 1663, Bochart stated that he had found in a manuscript of Leo Africanus, that Edrisi was born at Mazara, in Sicily, in 1098. Next year, however, the manuscript was edited by Hottinger, in an appendix to his work entitled *Bibliothecarius Quadripartibus*, when it appeared that the person supposed to be Edrisi was there named Esseriff Essachalli. Esseriff, or Scheriff, is indeed an usual appellation of Edrisi, but it is common to many, and is rather a title than a name. The rest of the name, and the date of birth, are materially different, so that there seems very little reason to doubt that Bochart was here mistaken.

The most positive statement on the subject is that of Casiri, who says (*Bibliotheca Arabico-Hispanica*, ii. 9), that if Edrisi, as appeared probable, were the person designated by the Mohammedan writers under the long appellation of Abu Abdallah Mohamad Ben Mohamad Ben Abdallah Ben Edris, he was born at Septa, or Ceuta, on the coast of Morocco, in the year of the Hegira 493 (A.D. 1099). Casiri not only qualifies his statement with this condition, but he does not state the authorities from which it is derived; so that it rests only upon the confidence reposed in his learning and accuracy. Edrisi was long a mighty name in Northern Africa; but in 919 the dynasty was subverted by Mahedi Abdallah, and the proscribed wrecks of the fa-

mily, according to D'Herbelot, afterwards sought refuge in Sicily. This certainly tends to strengthen the Sicilian origin of our author, though it is not probable that many would seek refuge by concealment in their native country.

If we may trust the information of Casiri, Edrisi pursued his studies at Cordova, and from the accurate description he has given of Spain, it is probable that he had travelled through a great part of that country. Various circumstances prove that he removed to Sicily, and began to compose his great work under the patronage, and indeed at the express desire, of Roger II. king of that island. It was completed about the year of the Hegira 548, A.D. 1153.

It has been a subject of pretty warm controversy among the learned whether Edrisi was a Mohammedan or a Christian. Sionita, who adopts the latter opinion, observes that he calls our Saviour the Lord, and also speaks with profound respect of the holy Virgin, and of various saints. These arguments are strenuously repelled by Hartmann, who lays much stress on the circumstance that Edrisi, amongst his numerous names, bears that of Mohammed; but though this may imply that he was a Mohammedan by birth, it does not authorize us to infer that he may not have become a convert to the opposite faith. Although he writes in a style from which no positive inference can be drawn, yet considering how high religious differences ran in that age, it does not appear very probable that he could have resided in Sicily, or been in such high favour with Roger, without adopting the religion of the monarch and country.

Bochart has fixed the date of his death in the year 1122; but this date clearly proves that he had some quite different person in view; since it appears by the preface to Edrisi's own work that its completion took place in the year 1153. No other notice, nor even conjecture, relative to the time or manner of his death, is to be found in any author.

His work has appeared under various titles. The first and fullest appears to have been, *The going out of a Curious Man to explore the Regions of the Globe, its Provinces, Islands, Cities, and their Dimensions and Situation.* This is sometimes abbreviated. Sionita published it under the name of *Relaxation of the Curious Mind;* but the title of *Nubian Geography,* which he and his companion imposed upon it, is altogether arbitrary.

The work contains a full description of the whole world, as far as it was known to the author, with its countries, cities, and all its features, physical and political. The world is divided into seven *climates,* commencing at the equinoctial line, and extending northwards to the limit at which the earth is supposed to be rendered uninhabitable by cold. Each climate is then divided by perpendicular lines into eleven equal parts, beginning with the western coast of Africa, and ending with the eastern coast of Asia. The whole world is thus formed into 77 equal square compartments, resembling those upon a chess-board, or those formed upon a plane map, by the intersecting lines of latitude and longitude. The geographer begins with the first part of the first climate, including the western part of Central Africa, and proceeds eastward through the different divisions of this climate, till he finds its termination in the Sea of China. He then returns to the first part of the second climate, and so proceeds till he reaches the eleventh part of the seventh climate, which terminates in the north-eastern extremity of Asia. The inconveniences of such an arrangement must be abundantly obvious.

The only valuable unpublished manuscripts of Edrisi which now exist in Europe are two which are preserved in the Bodleian Library. The first, which was brought over from Egypt by Greaves, is written in the Arabic character peculiar to Northern Africa. It is illustrated by a map of the known world, and by 33 other maps, containing each part of a climate, so that there are maps only for the first three climates. The second manuscript, brought by Pococke from Syria, is written in the Arabic character, as used in that country, and bears the date of 906 of the Hegira, or A.D. 1500. It consists of 320 leaves, and is illustrated by one general and 77 particular maps, the last consequently including all the parts of every climate. The general map has been published by Dr Vincent in his *Periplus of the Erythræan Sea.*

There is a manuscript (Cod. DLXXX) in the Royal Library at Paris, which professes to be the production of Edrisi; but D'Herbelot, it appears, has not made use of it as such; and De Guignes expresses positive disbelief on the subject. Hartmann, however, found it to coincide in many particulars with the geography of Edrisi. A copy of our author's work was contained at one time in the library of the Escurial, but it was destroyed by a great fire in 1671.

The geography of Edrisi, in the original Arabic, was printed at Rome in 1592, at the Medicean press, from a manuscript preserved in the grand-ducal library at Florence. Both the paper and printing are exceedingly neat, but the volume swarms with typographical errors, and forms only a clumsy epitome of the original work. The description of Mecca, which is unaccountably omitted, has been supplied by Pococke from his manuscript. Hartmann, D'Herbelot, and Casiri justly remark the imperfections of this edition. In most bibliographical works, this impression has been characterized as one of the rarest of books; but Adler, in a visit to Florence, found in the palace there 1129 copies, which were publicly exposed to sale at a moderate rate.

In 1619, two oriental scholars, Gabriel Sionita and John Hezronita, published at Paris a Latin translation of Edrisi's work, bearing the title of *Geographia Nubiensis;* but it is not executed with all that accuracy which might have been expected, particularly in regard to the proper names. George Hieronymus Velschius, an eminent German scholar, had prepared a copy of the Arabic original, with a Latin translation, which he intended to have illustrated with notes; but death prevented the execution of this design, and his manuscript remains deposited in the library of the university of Jena. Casiri (*Bibliotheca Arabico-Hispanica,* ii. 13) mentions that, at the request of many friends, he had determined to re-edit this work, but he appears never to have executed this intention. The part relating to Africa, preeminent certainly in point of importance, has been very ably edited by Hartmann, who has collected together all the notices relating to each particular country, and has annexed the statements of the countrymen and contemporaries of Edrisi, so that his work forms nearly a complete body of Arabian geography, as far as relates to Africa. (H.M.)

EDUCATION. See NATIONAL EDUCATION, and UNIVERSITIES.

EDULCORATION (low Lat. *edulco,* from *dulcis, sweet*), is used in chemistry to signify the rendering substances more mild, by freeing them from acids and salts, or other soluble impurities, by washing until the water comes off quite pure and insipid.

EDWARD, the name of several kings of England. See ENGLAND.

EDWARDS, GEORGE, fellow of the Royal and Antiquarian Societies, was born at Stratford, a hamlet belonging to Westham in Essex, on the 3d of April 1693. After having spent some time at school, he was put as apprentice to a tradesman in Fenchurch Street. His master, who was eminent both for his piety and skill in the languages, treated him with very great kindness; but about the middle of his apprenticeship an accident happened which totally put a stop to the hopes of young Edwards advancing himself in the way of trade. Dr Nicolas, a person of emi-

nence in the physical world, and a relation of his master's, happened to die. The doctor's books were removed to an apartment occupied by Edwards, who eagerly employed all his leisure hours, both during the day and great part of the night, in perusing those which treated of natural history, sculpture, painting, astronomy, and antiquities. The reading of these books entirely deprived him of any inclination which he might have formerly had for mercantile business, and he resolved to travel into foreign countries. In 1716 he visited most of the principal towns in Holland, and in about a month returned to England. Two years afterwards he took a voyage to Norway, at the invitation of a gentleman who was disposed to be his friend, and who was nephew to the master of the ship in which he embarked. At this time Charles XII. was besieging Frederickshall, an operation which prevented our young naturalist from making such excursions into the country as he would otherwise have done, for the Swedes were very careful to intercept such strangers as could not give a good account of themselves. But notwithstanding all his precaution he was confined by the Danish guard, who supposed him to be a spy employed by the enemy to procure intelligence of their designs. However, by obtaining testimonials of his innocence, a release was granted. In 1718 he returned to England, and next year he visited Paris by the way of Dieppe. During his stay in France he made two journeys of one hundred miles each, the first to Châlons in Champagne, in May 1720, and the second on foot to Orleans and Blois; but an edict happening at that time to be issued for securing vagrants, in order to transport them to America, as the banks of the Mississippi wanted population, our author narrowly escaped a western voyage. On his arrival in England, Mr Edwards closely pursued his favourite study of natural history, applying himself to drawing and colouring such animals as fell under his notice. In this pursuit he paid a strict attention to natural rather than to picturesque beauty. Birds first engaged his particular attention; and having purchased some of the best pictures of them, he was induced to make a few drawings of his own, which were admired by the curious, who encouraged the young naturalist to proceed, by paying a good price for his early labours. Amongst his first patrons and benefactors may be mentioned Mr James Theobalds of Lambeth, a gentleman zealous for the promotion of science. Being thus unexpectedly encouraged, he increased in skill and assiduity, and, by application to his favourite pursuit, procured a decent subsistence and a large acquaintance. However, he remitted his industry in 1731, when, in company with two of his relations, he made an excursion to Holland and Brabant, where he collected several scarce books and prints, and had an opportunity of examining the original pictures of several great masters at Antwerp, Brussels, Utrecht, and other cities. In December 1733, by the recommendation of Sir Hans Sloane, then president of the College of Physicians, he was chosen librarian to that body, and had apartments assigned him in the college. This office was peculiarly agreeable to his taste and inclination, as he had the opportunity of a constant recourse to a valuable library filled with scarce and curious books on the subject of natural history, which he so assiduously studied. By degrees he became one of the most eminent ornithologists in this or in any other country. His merit in this respect is too well known to render it necessary to pronounce any eulogium on his performances; but it may be observed, that he never trusted to others what he could perform himself, and he often found it so difficult to satisfy his own mind, that he frequently made three or four drawings in order to delineate the object in its most lively character, attitude, and representation. In the year 1743, the first volume of the *History of Birds* was published in quarto. As the number of his subscribers exceeded even his most sanguine expectations, a second volume appeared in 1747. The third volume was published in 1750; and in 1751 appeared the fourth volume. This being the last which he intended to publish at that time, he seems to have considered it as the most perfect of his productions in natural history; and therefore devoutly offered it up to the great God of nature, in humble gratitude for all the good things which he had received from Him in this world. Our author, in 1758, continued his labours under a new title, that of *Gleanings of Natural History*. A second volume of the Gleanings was published in 1760. The third part, which formed the seventh and last volume of his works, appeared in 1764. Thus our author, after a long series of years, the most studious application, and the most extensive correspondence in every quarter of the world, concluded a work which contains engravings and descriptions of more than six hundred subjects in natural history not before described or delineated. He likewise added a general index in French and English, which was afterwards perfected with the Linnæan names, by Linnæus himself, who frequently honoured him with his friendship and correspondence. Some time after Mr Edwards had been appointed librarian to the Royal College of Physicians, he was, on St Andrew's Day, in the year 1750, presented by the president and council of the Royal Society with the gold medal, the donation of Sir Godfrey Copley, annually given on that day to the author of any new discovery in art or nature, in consideration of his natural history just then completed. A copy of this medal he had afterwards engraved, and placed under the title in the first volume of his history. He was a few years afterwards elected fellow of the Royal Society and of the Society of Antiquaries, London, and also a member of many of the academies of sciences and learning in different parts of Europe. In return for these honorary distinctions from learned bodies, he presented elegantly-coloured copies of all his works to the Royal College of Physicians, the Royal Society, the Society of Antiquaries, and to the British Museum; and also to the Academy of Sciences at Paris, from which he received a very polite and obliging letter of thanks by their then secretary M. Defouchy. His collection of drawings, which amounted to upwards of nine hundred, were purchased by the Earl of Bute. They contain a great number of British as well as foreign birds, and other animals hitherto not accurately delineated or described. After the publication of the last work, having arrived at his seventieth year, he found his sight beginning to fail, and his hand losing its wonted steadiness. He retired from public employment to a little house which he had purchased at Plaistow, previously to which he disposed of all the copies as well as plates of his works. The conversation of a few select friends, and the perusal of a few select books, were the amusement of the evening of his life; and now and then he made an excursion to some of the principal cities in England, particularly to Bristol, Bath, Exeter, and Norwich. Some years before his death, the alarming depredation of a cancer, which baffled all the efforts of medical skill, deprived him of the sight of one of his eyes; and he also suffered much from the stone, to which at different periods of his life he had been subject; but in the severest paroxysms of pain he was scarcely known to utter a single complaint. Having completed his eightieth year, emaciated with age and sickness, he died, deservedly lamented, on the 23d of July 1773.

Edwards, *Bryan*, the well-known historian of the *West Indies*, was born at Westbury, in Wiltshire, on the 21st of May 1743. His father had a small paternal estate;

but as this did not exceed L.100 per annum, he found it insufficient for the maintenance of a numerous family, and endeavoured to improve his circumstances by dealing in corn and malt. This hazardous trade proved, as it often does, only a means of more deeply involving his affairs; and he died in 1756, leaving a widow and six children in a very distressed situation. Mrs Edwards, however, had two opulent brothers in the West Indies, the eldest of whom, Zachary Bayly, possessing a princely fortune, and being of a very amiable and generous disposition, undertook the support and education of young Edwards. He had already been placed by his father at the school of Mr Foot, a dissenting clergyman at Bristol, where he had been taught the elementary branches of education; but, for some reason which he never was able to divine, that person was strictly prohibited from initiating him in any branches of classical learning. He gave a species of instruction, however, not usual in schools, and from which his pupil probably derived the greatest benefit. He was accustomed to make the boys write letters, or rather essays, on various subjects, such as the beauty and dignity of truth, the obligations to a religious life, the benefits of good education, and the like, giving them, where it appeared necessary, an outline of the arguments which might be employed on the subject. When the papers were given in, he made such observations as appeared proper, insisting at least that they should be correct in point of grammar and orthography. These exercises gave occasion to display the superior talents of Edwards, whose powers of elegant composition already began to appear. He soon became the favourite of his master, who liberally praised these youthful performances, and often transmitted them for the gratification of his parents. They were entirely satisfied; but when the care of his education devolved on his uncle, the agent employed by him at Bristol was much surprised to find an entire deficiency in classical knowledge, and, imputing the blame to the master, removed him immediately to a French boarding school in the same city. It is not said that he acquired here any great portion of Greek and Latin, but he became master of the French language, and having access to an extensive circulating library, cultivated a taste for reading which adhered to him throughout the whole of his future life.

In 1759, another uncle, the younger brother of him under whose care he had hitherto been, arrived in England. He, too, was possessed of an ample fortune, became member of parliament, first for Abingdon, and afterwards for his native town, and set up a splendid establishment in London. He appeared quite disposed to befriend young Edwards, and even took the latter to reside with him; but the nephew observes, that, after enumerating his external advantages, he had nothing else to say in favour of his uncle. What the bad qualities were which drew forth so unfavourable a sentence we are not informed; but in a few months they separated, and Edwards went out to his other uncle. In this friend he seems to have found every thing he could desire; the most enlightened mind, the sweetest temper, and the most generous disposition. To this was added a truly paternal regard for himself, which was returned with all the warmth of filial affection. His uncle, finding him possessed of literary talents, but deficient in classical acquirements, engaged a Mr Teale, a clergyman, and formerly master of a free grammar-school, to reside in his house, and give him the instruction of which he stood in need. This choice proved most acceptable to Edwards; he found in Mr Teale a man of extensive information, and one, too, possessing considerable taste in poetry. He viewed him, therefore, as a companion rather than as a teacher; but this relation between the tutor and pupil, however agreeable to both, was not favourable for instilling the dry principles of grammar and prosody. A much larger proportion of their time was spent in tasting the beauties of Dryden and Pope, and in laughing at the comic sallies of Molière. Mr Edwards, upon the whole, acquired, during this period, small Latin and less Greek; but he continued to practise composition, both in prose and verse; and the two companions sent occasional pieces to the colonial newspapers.

The time was now coming when Mr Edwards' talents were to be exercised in a wider sphere. His uncle dying, bequeathed to him his property; and in 1773 he became heir to the much larger estate of Mr Hume, also of Jamaica. His wealth and talents united, now entitled him to take a lead in the political concerns of the island. In 1784 he published *Thoughts on the Proceedings of Government respecting the Trade of the West India Islands with the United States of America.* This was followed by a speech delivered at a free conference between the Council and Assembly at Jamaica, held on the 25th of November 1789, on the subject of Mr Wilberforce's propositions in the House of Commons concerning the slave trade. It was in 1793, however, that he published his great work, on which he had been many years engaged, entitled *History, Civil and Commercial, of the British Colonies in the West Indies*, 2 vols. 4to. He begins the work by giving a view of the original inhabitants of the West Indies, their manners, institutions, and the means by which they have been so entirely exterminated. This was followed by a sketch of the revolutions through which these islands have passed since the first European invasion. He gives next a geographical and statistical description of each particular island. He treats finally, at great length, of the government, the social state, and above all the commerce, of this remarkable region. In the course of the discussion, he enters fully into its relations with the African coast and the negro slave trade. Mr Edwards, as a great and long-resident proprietor, was almost inevitably led to be a supporter of this traffic. He reasons, however, in a liberal and candid manner on the question, and does not even attempt to deny the extent of the evils with which it was accompanied. He only insists that these evils have been overrated; and that Great Britain, by renouncing it whilst it was still prosecuted by the other nations of Europe, would ruin her own colonies, without doing any thing to improve the condition of the Africans. In 1796 he published, in one volume quarto, a *History of St Domingo*, an island which had excited a deep interest, in consequence of the insurrection of the slaves, and the consequent establishment of an independent negro government. In 1801 a new edition of both these works was published, in three vols. 8vo, under the general title of *History of the West Indies.* A fifth edition issued from the press in the year 1819. When Park returned from his celebrated journey, Mr Edwards, from his oral information, drew up a report of it, which was submitted to the African Society, and published in their *Transactions.* Mr Park afterwards incorporated the greater part of this into the general narrative of his *Travels*, in preparing which he availed himself much of the assistance and suggestions of Mr Edwards. It has been currently said that this narrative was entirely written by Mr Edwards; but as this assertion has been pointedly contradicted by Park, who has elsewhere shown respectable talents for composition, it can only be understood in the limited sense which has now been stated. It appears, however, that Mr Park was induced, by Mr Edwards' influence, to give rather a more favourable view of the trade in slaves than reflection afterwards led him to sanction.

Mr Edwards, after his removal to England, took up his residence at Polygon, near Southampton; and in 1796 he

became member of parliament for the borough of Grampound, which he continued to represent till his death, which took place on the 15th of July 1800. He left a short narrative of his life, which was prefixed to the edition of his history published in 1801. (H.M.)

EDWARDS, *Jonathan*, a celebrated American metaphysician and divine, was born on the 5th of October 1703, at Windsor, in the province of Connecticut. His family had originally emigrated from England in the reign of Queen Elizabeth. His father, Mr Timothy Edwards, was a clergyman of great piety and respectability, and by his mother he was grandson of Mr Solomon Stoddard, a noted and zealous divine of Northampton. Jonathan was accordingly reared in the bosom of Puritanism, and all his ideas were early imbued with the cast of thought which was native to the stock from which he had sprung. There was something indeed not a little singular in the prevailing character of religion in America in those days. A conversion seems to have been a regular era in a man's life, which could be fixed down to a date, as much as his coming of age or his being married. A very curious document remains of Jonathan's conversion, the whole steps and progress of which he has detailed for the behoof of his children; and it is a document which, even amidst all its frequent weakness and extravagance, impresses us with a high sense of the genius and of the worth of this remarkable man. We cannot avoid giving our readers a little insight into it, especially as it contains some passages of deep feeling and sensibility, which form a striking contrast to the controversial hardness of his other writings. It is full of bursts of tenderness; and even whilst the subjects of his earliest meditations were the same dark doctrines, in their most tremendous form, which he afterwards defended so ably by the help of his mature reason, amidst all the gloom which naturally surrounds them, they seem to have left upon his mind no sentiments but those of gentleness and charity. At the same time, this document affords us a distinct proof that such doctrines take their origin, in a great measure, in peculiar circumstances of society, or of the individual mind; and since they were quite as fully impressed upon Edwards before he was capable of any profound reasoning concerning them, as afterwards, the presumption is, that his early prepossessions came strongly in aid of his later conclusions.

It was in the midst of these youthful musings that he acquired a full and firm persuasion of tenets which we will own scarcely seem to us to be either so lovely, or of so good report, as the more natural sentiments of his unconverted state, which he gave up in exchange for them. "I had a variety," says he "of concerns and exercises about my soul from my childhood; but had two more remarkable seasons of awakening before I met with that change by which I was brought to those new dispositions, and that new sense of things, that I have since had. The first time was when I was a boy, some years before I went to college, at a time of remarkable awakening in my father's congregation. I was then very much affected for many months, and concerned about the things of religion." This state of mind, however, appears to have passed off; but, in his last year at college, he was visited by a severe sickness, which made him form many wise and holy resolutions, which he was afterwards for the most part enabled to keep. So far it was well; but now follows the grand proof of his conversion. "From my childhood up," he says, "my mind had been wont to be full of objections against the doctrine of God's sovereignty in choosing whom he would to eternal life, and rejecting whom he pleased, leaving them eternally to perish, and be everlastingly tormented in hell. It used to appear like a horrible doctrine to me. But I remember very well when I seemed to be convinced and fully satisfied as to this sovereignty of God, and his justice in thus eternally disposing of men according to his sovereign pleasure. But I never could give an account how or by what means I was thus convinced, not in the least imagining in the time of it, nor a long time after, that there was any extraordinary influence of God's Spirit in it, but only that now I saw farther, and my reason apprehended the justice and reasonableness of it. However, my mind rested in it, and it put an end to all those cavils and objections that had till then abode with me all the preceding part of my life. And there has been a wonderful alteration in my mind with respect to God's sovereignty from that day to this, so that I scarce ever have found so much as the rising of an objection against God's sovereignty in the most absolute sense, in showing mercy to whom he will show mercy, and hardening and eternally damning whom he will. God's absolute sovereignty and justice, with respect to salvation and damnation, is what my mind seems to rest assured of as much as of any thing that I see with my eyes." This doctrine continued throughout Mr Edwards' life in peculiar favour with him; and he employs the whole resources of his dialectics to support it, with a full conviction that he was thereby glorifying God, and performing an important service to mankind.

In this document of Mr Edwards' early opinions, we have said that, amidst all the horrors of his creed, there are many intimations of the natural fineness and sensibility of his spirit. The following passages are remarkably beautiful, and have about them a tone of pastoral or rather scriptural poetry. "Not long after I first began to experience these things, I gave an account to my father of some things that had passed in my mind. I was pretty much affected by the discourse we had together; and when the discourse was ended, I walked abroad alone in a solitary place in my father's pasture for contemplation. And as I was walking there, and looked up on the sky and clouds, there came into my mind so sweet a sense of the glorious majesty and grace of God that I know not how to express it....God's excellency, his wisdom, his purity and love, seemed to appear in every thing; in the sun, moon, and stars; in the clouds and blue sky; in the grass, flowers, trees; in the water and all nature, which used greatly to fix my mind. I often used to sit and view the moon for a long time, and so in the day time spent much time in viewing the clouds and sky, to behold the sweet glory of God in these things; in the mean time singing forth with a loud voice my contemplations of the Creator and Redeemer...I used to be a person uncommonly terrified with thunder; and it used to strike me with terror when I saw a thunder-storm rising; but now, on the contrary, it rejoiced me. I felt God at the first appearance of a thunder-storm, and used to take an opportunity at such times to fix myself to view the clouds, and see the lightnings play, and hear the majestic and awful voice of God's thunder." These confessions have let us already into the inside of Edwards' mind, and there is no need to return upon them whilst we pursue the account of his studies, life, and writings. There is a poetry and grandeur in some of his passages of this sort which show a moral sublimity of genius in the midst of enthusiastic reveries, often, in inferior minds, more productive of dark and disorderly sentiments than of sound and elevated piety. When he comes, however, to reason on his theological or philosophical tenets, he is no longer either an enthusiast or a poet; for he then proceeds with all the pertinacity and ingenuity of a hard-headed dialectician, determined neither to tolerate nor employ any weapon but stern argument.

He went young to Yale College, and as early as his thirteenth year had read Locke *On the Human Under*

standing with great delight and profit. He had a great taste for natural philosophy, but the moral and divine sciences were his chief object; and after a long residence at college, during which time he prepared himself assiduously for the ministry, he was in due form licensed to preach. In August 1722 he was invited to preach to the English Presbyterians at New York, where he continued with approbation above eight months; but as this society was too small to maintain a preacher, he returned in the year 1723 to his father's house at Connecticut, where, for some time, he applied to his studies with much industry and perseverance; and this severe application became habitual to him, although he was of a delicate constitution. In the spring of 1724, having taken his master's degree, he was appointed tutor of Yale College, being then in his twenty-first year; an office which, notwithstanding his youth, he filled for two years with great success and reputation. In September 1726 he received an invitation from the people of Northampton in Connecticut, to become assistant to his mother's father, Mr Stoddard, to whom he was ordained colleague in his twenty-fourth year, and continued as pastor of this congregation till the year 1750. During this time he married, had many children, and wrote several pious and useful treatises, chiefly suggested by the events of the times, such as his *Faithful Narrative of the Surprising Work of God, in the Conversion of many Hundred Souls in Northampton* (for these, as his biographer[1] tells us, were remarkable times for the out-pouring of God's Spirit); but particularly a sensible and useful treatise on *Religious Affections*, in which he endeavoured to restrain the extravagance and fanaticism into which, under these strong impressions, the religion of his flock was but too apt to degenerate. He was a most faithful and conscientious minister, but at last fell under the displeasure of his people, from no other cause except his anxiety for their spiritual interests. They appear, indeed, to have been a very stiff-necked generation, full of absurd whimsical vagaries on the subject of religion, but at the same time evincing little of its spirit in their lives and conversations. They had all a voice in the election and continuance of their clergyman, and they were very ready to seize any opportunity to show their power. Mr Edwards discovered that some licentious books had got among the youth of his congregation, a fact as to which he wished some investigation to take place; and this was the first point upon which his people flew off from him. There arose afterwards another point about the administration of the holy communion. His grandfather Mr Stoddard had, it seems, a notion that the administration of the sacrament was a moment which the Divine Spirit was much disposed to seize for the conversion of sinners; and that, therefore, the most notorious sinners were almost without scruple to be admitted to that holy ordinance, in the hope that this conversion would fall upon them. The result of this precious notion was, that the utmost licentiousness, mingled as it was with wild religious fancies floating in every brain, began to prevail amongst the people. When Mr Edwards, on his grandfather's death, obtained the entire charge, he endeavoured to make a change in this particular; but the outcry against him was loud and overbearing. Even his brethren of the clergy tamely gave way to a clamour which they condemned; and this excellent, able, and pious clergyman was thus driven away by the misguided flock, for whom he had laboured assiduously during twenty-four years; and at an advanced period of life, with a wife and a large family, he was thrown upon the world and the care of providence.

His next position was at Stockbridge, in the western part of Massachusetts Bay, where he was put at the head of a mission for converting the Indians. He was not enabled to do much as a missionary; but here he had a great deal of leisure, which he employed in writing his principal works. It was now he completed his chief treatise on the subject of free will; a work concerning the rapid execution of which we have the following information in Sir Henry Moncreiff Wellwood's able and interesting *Life of Dr Erskine*. "It was not till the month of July 1752, that he appears to have resumed his studies on the subject of free will; for on the 7th of that month he writes Dr Erskine, that 'he hoped soon to be at leisure to resume his design;' and gives him another sketch of the plan of his book, in which, though there be nothing new, there is more detail than in that which he had formerly sent him. Whatever opinion," continues this able writer, "may be held with regard to Mr Edwards' argument, it must appear astonishing to those who are capable of appreciating the difficulty of his subject, that, in nine months from the date of this letter, on the 14th of April 1753, he could write Dr Erskine, that he had almost finished the first draught of what he originally intended; though he was under the necessity of delaying the publication till he knew the result of proposals which he had circulated for printing his book by subscription. His book was published in 1754, and, though he had made some progress in preparing his materials before he left Northampton, was certainly written, and nearly completed, within the time ascertained by the two letters referred to, and must be admitted to convey a very striking idea, both of his mental resources and of his literary ardour."

In 1757, on the death of Mr Aaron Burr, Mr Edwards was chosen president of New Jersey College. He had only been here, however, a very short time, when he was carried off on the 22d of March 1758, in the fifty-fifth year of his age, by the small-pox. This disease was at that time raging in the neighbourhood. Mr Edwards, who had never had it, proposed to be inoculated, which his physicians approved of. He had the disease favourably, but a secondary fever set in, and by reason of a number of pustules in his throat, the obstruction became such that he could not swallow the necessary medicines, and the fatal result was what we have stated. The character of Mr Edwards is that of a very primitive, self-mortified, simple, and amiable man, and affords a strong proof of the power of genuine Christian piety upon the heart, in spite of the most gloomy and repulsive tenets. He was solely occupied with his professional duties and his theological studies, insomuch that, as is mentioned with inimitable simplicity by the author of his life, "he was less acquainted with most of his temporal affairs than many of his neighbours, and seldom knew when and by whom his forage for winter was gathered in, or how many milk-kine he had; whence his table was furnished," or by what means his wants were provided for. Mrs Edwards, however, a most valuable and sensible woman, fully supplied his defects in these particulars. We must quote another passage from this piece of biography, which is equal in simplicity, though by no means in any thing else, to some of the exquisite biographies of Isaac Walton. After being informed that he did not permit dancing, against which

[1] This primitive piece of biography, from which all our quotations are taken, is prefixed to a volume of sermons published after Mr Edwards' death. Its author is not mentioned. The edition from which we quote is printed at Edinburgh, by Alexander Jardine, 1799.

Edwards, Jonathan.

amusement, indeed, he wrote a sermon, we are told that "he allowed not his children to be from home after nine o'clock at night, when they went abroad to see their friends and companions; neither were they allowed to sit up much after that time, in his own house, when any came to make them a visit. If any gentleman desired acquaintance with his daughters, after handsomely introducing himself, by properly consulting the parents, he was allowed all proper opportunity for it, and a room and fire, if needed; but must not intrude on the proper hours of rest and sleep, nor the religion and order of the family."

Mr Edwards comes nearer Bishop Butler as a philosophical divine than any other theologian with whom we are acquainted. His style, like Butler's, is very much that of a man thinking aloud. In both these authors the train of thinking in their own minds is more clearly exhibited to us than perhaps by any other writer, whilst they show us with great truth and distinctness what their notions are, and how they came by them, with very little concern about the form of expression in which they are brought out. Butler, however, had a larger mind than Edwards, and was by no means so much of a mere dialectician. If, therefore, he be less acute than the American, he is more comprehensive, and gives fairer play to every opposing argument. We do not mean here to enter into any of Edwards' speculations. Both on the subject of original sin, and on the freedom of the will, he seems to us to unite a great deal too closely the views which originated, as we have seen, in no small degree, amidst his early reveries, with the infallible discoveries of divine revelation. Our notion is, that in all discussions on such subjects which have hitherto appeared, the speculatists have forgotten how little a part either of the history or the nature of man we are in fact acquainted with; and how ready we ever are, in laying the foundations of our theories, to place a tortoise beneath the elephant. The whole difficulty, for instance, on the freedom of the will, turns upon a puzzle in the idea of cause and effect. Perhaps this idea is far from being precise in our minds (Mr Edwards uses it very loosely in his speculations); yet we do not scruple, in our reasonings upon it, to draw the most positive inferences from the assumptions with which we set out. We suspect, indeed, that the true and accurate notion of causation always involves the idea of volition; and, on that supposition, to ask for the cause of volition itself is absurd. It may be very true that we cannot will to do any thing without previous thought or motive; neither can we think without previous existence. But is our existence the cause of our thinking? Just as much as our thinking is the cause of our willing. We are far, however, from wishing to add our own crude conceptions to those which have been piled up on this subject from the beginning of time to the present hour, without, we believe, doing the slightest service to the cause of moral and religious truth, or accomplishing any thing, in short, beyond affording an exercise for ingenuity, and too often a handle for uncharitable rancour and presumptuous absurdity. Mr Edwards, with all his great powers, has accordingly, we apprehend, done but little good to the world, we mean as a philosopher; for he did much good in his own day, whilst he was living the life of a zealous and faithful Christian minister. But it is "thus we play the fools with the time; and the spirits of the wise sit in the clouds and mock us." Exalted above all the folly of human wisdom, the spirit of this truly good and pious man is now, it may be, disposed to regard with some such sentiment many of his own most severe and laborious speculations, which were carried on in the serious belief, that if "the knots of Calvinism were trimmed off, or its doctrines, in the whole length and breadth of them, were not rigidly maintained, a man could nowhere set his foot down with consistency and safety, short of Deism, or even Atheism itself, or rather universal Scepticism."

Eecloo ‖ Eger.

Edwards' works consist of several volumes of sermons, printed at various times, and often reprinted in this country as well as in America. Besides these, he wrote, 1. *A Treatise concerning Religious Affections*, 1746, 8vo; 2. *An Account of the Life of the Reverend David Brainerd*, 1749, 8vo; 3. *An Inquiry into the Qualifications for full Communion in the Visible Church*, 1749, intended as a vindication of his principles in the matter which occasioned his dismission from Northampton; 4. *A careful and strict Inquiry into the Modern Notion of that Freedom of Will which is supposed to be essential to Moral Agency*, 1754; 5. *The Great Christian Doctrine of Original Sin defended, containing a Reply to the Objections of Dr John Taylor*, 1758; 6. *A History of Redemption*; 7. *Miscellaneous Observations on Important Theological Subjects*, London, 1793; 8. *Remarks on Important Theological Controversies*, ibid. 1796. Some of these were posthumous, as were a few other tracts of less importance written by him. (R. M.)

EECLOO, a town of Belgium, province of East Flanders, situated on the high road between Ghent and Bruges, 12 miles N.E. of the former. Pop. (1851), 8884. The town is generally well-built, and has an ancient convent, a town-hall, prison, several churches, and numerous schools Manufactures—woollen and cotton goods, soap, tobacco, chocolate, and hats; besides distilleries, tanneries, salt refineries, and oil mills. A large weekly market for grain, cattle, &c. is held here.

EEL. See Ichthyology.

EFFENDI, a Turkish word signifying *master*, frequently subjoined as a title of respect to the names of persons, particularly to those of ecclesiastics and learned men. The grand chancellor of the empire is called *Reis Effendi*, abbreviated from *Reis-al-Kottâb*, which signifies "the chief of secretaries or writers."

EFFERVESCENCE. When an acid is added to a carbonate, the phenomena of bubbles, vapours, and small jets of liquid, attended with a hissing noise, are occasioned by the disengagement of gas; and this species of intestine motion is termed effervescence. Sometimes also effervescence is accompanied with a great degree of heat, from the decomposition of some substances and the formation of new compounds.

EFFIGY (*effigies*), the portrait, image, or representation of a person. It also denotes the impression of a coin, representing the head of the prince who struck the coin. To *hang*, or *burn in effigy*, is to burn or hang an image or picture of the person intended to be executed or degraded. In France, this was formerly done in the case of any criminal who could not be apprehended—his image or picture being hung on a gibbet, below which was written his sentence of condemnation.

EFFLORESCENCE, in *Chemistry*, the formation of a kind of mealy powder on the surface of certain bodies. It is occasioned either by decomposition or by drying. The efflorescence which happens to cobalt and martial pyrites is of the former kind; and that observed on the crystals of soda, Glauber's salt, &c., is of the latter kind. An efflorescence is sometimes also a species of crystallization, such as the beautiful vegetations which shoot up from different saline substances. See Crystallization.

The term is used in botany to denote the time of flowering.

EFFLUVIUM, a term used to express the minute particles which exhale from most, if not all, terrestrial bodies, in the form of sensible vapours.

EGER, (Boh. *Cheb*), a frontier town of Bohemia, capital of a cognominal circle, situated on a rocky eminence on

the right bank of the Eger, 94 miles west of Prague. Pop. about 10,000. It was formerly strongly fortified, but its walls are now almost destroyed, and the ditches have been filled up. There are several handsome buildings in the town, including a fine parish church, and a spacious town-hall. At the east end of the market-place is the burgomaster's house, in a bed-room of which Wallenstein was assassinated in 1634. Situated in an angle of the fortifications, on a rock, are the ruins of the imperial castle, containing an ancient square tower built of massive blocks of volcanic tuff, and regarded by some as a work of the Romans. The double chapel is an interesting specimen of Gothic architecture;—the lower story which existed in 1213 is supported by granite pillars, with ancient capitals; the upper story rests on four slender marble columns with pointed arches, and singularly carved capitals bearing gnostic and other symbols. Adjoining the chapel is the castle-hall where the friends of Wallenstein were treacherously murdered previous to his own assassination. Eger has manufactures of cotton and woollen stuffs, chintz, leather, soap, &c. An avenue nearly three miles in length, leads from this town to Tranzensbad, or Tranzensbrann, celebrated for its mineral springs.

EGERIA, or ÆGERIA, in *Roman Mythology*, a nymph of Aricia in Italy, from whom Numa is said to have received instructions respecting the laws and regulations which he introduced at Rome. According to the legend, they had frequent interviews by night in the Lucus Camenarum—a grove near the Porta Capena, in the valley now called La Caparella. When Numa died, the disconsolate Egeria retired to the grove of Aricia, on the borders of the Lacus Nemorensis (Nemi); and by her tears and lamentations so frequently interrupted the worship of Diana, that the goddess, in commiseration, transformed her into a fountain. Egeria was regarded as a prophetic divinity; and, as presiding over childbirth, she was invoked by pregnant women. Hence by some she has been identified with Lucina (Liv., i. 19.; Ovid, *Met.* xv. 431, &c.; Virg., *Æneid*, vii. 761), &c.

EGG, in *Physiology*, a body formed in certain females, in which is contained an embryo or fœtus of the same species, under a cortical surface or shell. The exterior part of an egg is a shell, which in a hen, for instance, is a white, thin, and friable cortex, including all the other parts. The shell becomes more brittle by being exposed to a dry heat. It is lined everywhere with a very thin but pretty tough membrane, which dividing at or very near the obtuse end of the egg, forms a small bag, where only air is contained. In new-laid eggs this follicle appears very little, but becomes larger when the egg is kept. Within this are contained the albumen or white, and the vitellus or yolk; each of which has its different virtues. The albumen is a viscous, white liquor in the egg, different in its consistence in its different parts. It is observed, that there are two distinct albumens, each of which is inclosed in its proper membrane. Of these, one is very thin and liquid, the other is more dense and viscous, and of a somewhat whiter colour, but, in old and stale eggs, after some days' incubation, inclining to a yellow. As this second albumen covers the yolk on all sides, so it is itself surrounded by the other external liquid. The albumen of a fecundated egg is as sweet and free from corruption during the whole time of incubation as it is in new laid eggs; and so is also the vitellus. The eggs of hens consist of two liquors separated one from another, and distinguished by two branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen. When the vitellus grows warm with incubation, it becomes more humid, resembling melting wax or fat; and hence it occupies more space. For as the fœtus increases, the albumen insensibly wastes away and condenses: the vitellus, on the contrary, seems to lose little or nothing of its bulk when the fœtus is perfected, and only appears more liquid and humid when the abdomen of the fœtus begins to be formed. The chick in the egg is first nourished by the albumen, and, when this is consumed, by the vitellus, as with milk. If we compare the *chalazæ* to the extremities of an axis passing through the vitellus, which is of a spherical form, this sphere will be composed of two unequal portions, its axis not passing through its centre; consequently, since it is heavier than the white, its smaller portion must always be uppermost in all positions of the egg. The yellowish-white round spot, called *cicatricula*, is placed on the middle of the smaller portion of the yolk; and therefore, according to what has been said above, must always appear on the superior part of the vitellus. Not long before the exclusion of the chick, the whole yolk is taken into its abdomen; and the shell, at the obtuse end of the egg, frequently appears cracked some time before the exclusion of the chick. The chick is sometimes observed to perforate the shell with its beak. After exclusion, the yolk is gradually wasted, being conveyed into the intestines by a small duct.

Eggs differ very much, according to the birds which lay them, as to their colour, form, size, age, and the different ways of dressing them. Those most used in food are hens' eggs. As to the preservation of eggs, it is observed that the egg is always quite full when it is first laid by the hen; but from that time it gradually becomes less and less so, till its decay; and, however compact and close its shell may appear, it is nevertheless perforated with a multitude of small holes, though too minute to be discerned by the naked eye, the effect of which is a daily decrease of matter within the egg, from the time of its being laid. This perspiration is much quicker in hot weather than in cold. To preserve the egg fresh there needs no more than to preserve it full, and stop its transpiration; the method of doing which is, by stopping up those pores with matter which is not soluble in watery fluids; and on this principle it is that all kinds of varnish, prepared with spirit of wine, will preserve eggs fresh for a long time, if it be carefully rubbed all over the shell. Butter, or mutton fat, is also good for this purpose.

EGHAM, a village of Surrey, 18 miles W. of London, on the Thames, and connected with Staines on the opposite side of the river by an iron bridge. In the vicinity is Runnymede, famous in English history as the scene of the conference between King John and his barons, which ended in the signing of the Magna Charta, A.D. 1215; and Cooper's Hill, celebrated by Denham and Pope.

EGINHARD. See ÆGINHARD.

EGNATIA, or GNATIA, a city of Peucetia, a province of Apulia, situated on the coast, the inhabitants of which are ridiculed by Horace for exciting the wonder of the ignorant multitude by burning incense on an altar without the process of ignition. This city gave name to the Via Egnatia, which passed from Brundusium through Egnatia to Canusium. Its ruins are found at the *Torre d'Agnazzo*, where the inhabitants still pretend to show the temple alluded to by Horace.

EGREMONT, a small market-town of England, county of Cumberland, on the Ehen, 2½ miles from the coast. The parish church, St Mary's, is an ancient edifice. The ruins of Egremont castle stand on an eminence near the town. Large quantities of iron ore are excavated in the neighbourhood. Market-day Saturday. Pop. of parish 2049.

EGLANTINE, a name of the sweet-briar, *Rosa rubiginosa*, so frequently alluded to by our old poets. Warton justly observes—that Milton in the *Allegro* has applied the word improperly to the *honeysuckle*.

> Then to come, in spite of sorrow,
> And at my window bid good-morrow,
> Through the sweet-briar or the vine,
> Or the twisted eglantine.

EGRET. See index to ORNITHOLOGY

EGYPT.

SECTION I.

PHYSICAL GEOGRAPHY, PRODUCTIONS, AND INHABITANTS.

Egypt.

Egypt, a country situate at the north-eastern extremity of Africa, between N. Lat. 31. 37. and 24. 1., and E. Long. 27. 13. and 34. 12.;[1] bounded on the N. by the Mediterranean Sea, on the S. by Nubia, on the E. by Palestine, Arabia, and the Red Sea, and on the W. by the Great Desert.

Names of Egypt.

In the hieroglyphic inscriptions the proper name of Egypt is Kem, and it was therefore thus called by its ancient inhabitants. The pronunciation of this name cannot be regarded as perfectly certain, since the first consonant may perhaps be "ch,"[2] and the vowel is not expressed. The Coptic form is χημι or χαμη in the Memphite dialect, and κημε or κημη in the Theban. The name signifies, both in Egyptian[3] and in Coptic, "black," and is said to have been given to the country by reason of the blackness of its cultivable soil.[4] The other names of Egypt in its ancient language appear to be appellations of a poetical character.

Egypt is usually called in the Hebrew Scriptures מִצְרַיִם *Mizraim.* In the enumeration of the descendants of Noah, we find Mizraim among the sons of Ham,[5] and it has been hence concluded this is the name of an individual as well as of Egypt. In the Old Testament, however, men are called the fathers of tribes and of cities;[6] and the name Mizraim, although used as a singular, being dual in form, is manifestly applicable to a country naturally divided into two regions, and so divided by its ancient inhabitants. This name in the singular form מָצוֹר, *Mazor,* is sometimes given to Egypt in the Bible. The latter is the same as the Arabic name مصر *Misr,* pronounced in the vulgar dialect *Masr,* and signifying "red mud." By red (أحمر *ahmar*), the Arabs mean both red and reddish brown; and the Egyptian Kem signifies either a dark colour generally, or particularly (and this is more probable) that of the tail of the crocodile, the first hieroglyphic of the group (which is read Kem), which varies, in different individuals, from a slaty to a reddish brown.[7] The ordinary Hebrew and Arabic name of Egypt is therefore of the same signification as the hieroglyphic one. We also find Egypt called in the Old Testament "the land of Ham," חָם,[8] and mention is made therein of "the tabernacles of Ham."[9] This may refer to the patriarch or to the Egyptian name; and as the patriarch's name signifies in Hebrew "hot" or "warm," and we find in Arabic, a sister language, a cognate word حمأ *hama,* fetid black mud,[10] the two may be regarded as identical with each other and with Mazor. Since the name of the patriarch is so appropriate to Egypt, it is most reasonable to suppose that it was given him prophetically as the progenitor of the sun-burnt inhabitants of this and neighbouring lands; and it must be borne in mind, that both Noah and Japhet, and probably Shem also, were so named. Besides the biblical names of Egypt above mentioned, there is also רַהַב *Rahab,* signifying "the Proud."

The Arabic name of Egypt, Misr, is given to that country by its modern inhabitants. It first occurs, as far as is known, in the Kur-án, as in the following passage, "And Pharaoh proclaimed among his people, saying, O my people, doth not the government of Misr belong to me?"[11] where Misr signifies Egypt.[12]

The name of Egypt, written Misr, is stated by Colonel Rawlinson to be found in the cuneiform inscriptions of Assyria.

The etymology of the common Greek name of Egypt, Αἴγυπτος, whence ours is derived, has occasioned much discussion. The most probable derivation is αἶα "land," and Γυπτος a proper name. This "Guptos" seems equivalent to Coptos, the Coptic κεβτω, κεπτο, κεπτω, κεϥτ, and Arabic قفط, *Kuft,* a town in Upper Egypt, radically the same as the name of the Egyptian Christians, Copts. In hieroglyphics Coptos is called Kebt-hor,[13] which is clearly the same as the biblical Caphtor; and since Kebt-hor is identical with Coptos, Caphtor may be with "Guptos." In the enumeration of the sons of Mizraim we find the Caphtorim,[14] and elsewhere the country called Caphtor is mentioned. In the book of Jeremiah, אִי כַפְתּוֹר "Iy-Caphtor"[15] that is, "the island" or "coast" (whether bordering on a sea or river) "of Caphtor" is spoken of; and this expression seems to be the very origin of Αἴγυπτος. A historical inquiry, for which there is not space in the present article, lends additional weight to the probability of this etymology.[16]

Geographical position.

By the Greeks and their contemporaries Egypt was generally held to be a country of Asia, though some assigned it to Libya,[17] that is, Africa. The reason of this difference

---

[1] These limits are those of the northern coast.

[2] Certain letters of the Egyptain alphabet had a double pronunciation, either in the language generally, according to their position, or in different dialects. That rendered "k" is probably one of these, and sometimes held a middle place between the simple "h" and the rough "kh," being a "ch" (χ) or "hh."

[6] See Gen. x. 15, *et seqq.*, where it is said that "Canaan begat Sidon, his first-born [not necessarily the city so called], and Heth, and the Jebusite, and the Amorite," as well as other tribes. In 1 Chron. we find mention of "Shobal the father of Kirjath-jearim, Salma the father of Beth-lehem, Hareph the father of Beth-gader" (ii. 50, 51); and a little farther occur these words, "The sons of Salma, Beth-lehem, and the Netophathites" (*Id.* 54.)

[7] Comp. Horapollo Nilous Σκότος δὲ λέγοντες, κροκοδείλου οὐρὰν ζωγραφοῦσιν· ἐπειδὴ οὐκ ἄλλως εἰς ἀφανισμὸν καὶ ἀπώλειαν φέρει ὁ κροκόδειλος οὗ ἐὰν λάβηται ζώου, εἰ μὴ τῇ οὐρᾷ τῇ ἑαυτοῦ διαπληκτίσας ἄτοπον [or ἄτονον] παρασκευάσει. ἐν τούτῳ γὰρ τῷ μέρει ἡ τοῦ κροκοδείλου ἰσχὺς καὶ ἀνδρεία ὑπάρχει. *Ed. Cory.*, l. i., c. lxx., p. 87. It is to be observed that the facts stated by Horapollo are usually much more reliable than his explanations of them, or those of his translator Philip, to whom we may ascribe much of the contents of the work. In selecting symbols the ancient Egyptians seem to have chosen those representing as obviously as possible the idea which they were desirous to embody, but the philosophical interpreters of their system sought to explain those symbols in an abstruse manner.

[16] The Bible relates that the Philistines came out of Caphtor, and as well as the Egyptian monuments, shows that the Philistines and Cretans were most probably kindred peoples, and thus the name Αἴγυπτος, if the same as "Iy-Caphtor," would be traceable to the maritime Greeks, who were at all times connected with Egypt.

[17] "Egypt, according to some, is of Asia, and according to others, of Libya."—Scholiast on *Apollonius Rhodius* (iv. 1571).

Egypt.

seems to have been twofold, partly because Egypt was socially Asiatic but by position African, and partly because the Nile, which intersects the country, was fixed upon as the boundary of Asia and Libya, so that half Egypt, or at least some part of it, would have been assigned to each of these continents. From this cause arose the opinion of the Ionians, which Herodotus mentions,[1] that what others have called Egypt, except the Delta, was half an Arabian country and half a Libyan; so that the Delta, their Egypt, should have been, as the historian remarks, reckoned a fourth division of the world by the Ionians, since they assigned it to neither Asia nor Libya.

Extent.

In ancient times Egypt was held to be the country overflowed by the Nile north of the First Cataract, and the Arabian and Libyan deserts and mountains which border that tract on the east and west were not considered part of it. Thus Herodotus relates that " they of the city of Marea and of Apis, who inhabit the parts of Egypt bordering on Libya, thinking themselves to be Libyans and not Egyptians, and being discontented at the usage concerning victims, desiring not to abstain from [eating the flesh of] cows, sent to [the oracle of] Ammon, saying that nothing was common to them and to the Egyptians, for they dwelt without the Delta, and did not speak the same language with them, and that they wished it might be allowed to them to eat all things: but the god did not permit them to do thus, saying, that Egypt was that [tract] which the Nile passing over waters, and the Egyptians those who, dwelling below the city Elephantine, drink of this river. Thus these things were replied by the oracle to them. Now the Nile reaches, when it swells, not alone the Delta, but also some part of the tract which is said to be Libyan, and of that which [is said to be] Arabian, even for a two days' journey on both sides, and [sometimes] yet more than this or less."[2] No more accurate description could be given of the Egypt of the ancients than this reply of the oracle of Jupiter Ammon. By the modern inhabitants, and by the Arabs, Egypt Proper is the same tract, but they differ from the ancients in calling the deserts those of Egypt, instead of assigning them to the adjoining countries. Modern European geographers, however (the Turks excepted), understand Egypt to comprehend the Eastern Desert to the Red Sea, and the Western as far as a little beyond the neighbouring oases, excepting that of Seewah, anciently that of Jupiter Ammon. The country watered by the Nile north of the First Cataract, and the deserts which bound it, have been always distinct naturally and politically, inhabited by two or more different races, a settled people, and a nomad, often at war with one another; and it has been easier to distinguish these tracts than to determine how much of either desert should be assigned to the inundated tract as part of Egypt, so that the ancient definition of that country seems by far the more reasonable of the two. That of the modern geographers is, however, now so generally received, that it is unadvisable to attempt to disturb it.

The political advantages of the situation of Egypt, and of its natural strength, as well as resources, can scarcely be overestimated. It lies in the very route of the trade between the East and the West. Not only has the commerce of Arabia and India in almost all ages passed through it, but its great river and caravans of camels have brought from Central Africa ivory and gold and negroes, since the patriarchal times. It has natural harbours on the coast of the Red Sea and that of the Mediterranean, the selection and improvement of the most important of which has been regarded as the wisest act of Alexander the Great, and certainly was that by which he most benefited posterity, if indeed he did so directly by any other.[3] The plain of Lower Egypt is hard to approach by land, and by reason of its intersection by the branches of the Nile and by canals, as well as the possibility of sometimes laying great portions of it under water, difficult to subdue, while the narrow valley of the Sa'eed, or Upper Egypt (otherwise called Middle and Upper) is made almost impregnable by the mountains and deserts which closely hem it in. The whole country is rendered independent of neighbouring lands by its extreme fertility, which makes its defence the easier. The ancient wealth and power of Egypt need therefore occasion us no wonder, and while we trace the causes of their decay, these natural advantages of position raise a hope for the future.

Superficies.

In the great French work on Egypt, there is an excellent memoir on the superficies of that country by Col. Jacotin,[4] which is both fuller and from a higher authority than anything else on the same subject: from this memoir the following remarks are taken:—M. Jacotin observes that Egypt, according to the maps of the best geographers, particularly of D'Anville, is situate between the meridians 26. 30., and 32. 20. E. Long. (that is from the meridian of London, or rather Greenwich, 28. 50. and 34. 40. E. Long.), and the parallels 24. 1. 25., and 31. 37. 0. N. Lat. The surface contained within these limits may be computed to be 20,000 square leagues, or 115,200 square geographical miles.[5] This must be considered as a very approximative calculation, since the limits of Egypt, when the deserts are included, are necessarily extremely vague. The space which the Nile does or can water and fertilize, including its bed, north of the First Cataract, is only 9582·3936 square miles, or about a twelfth of the whole superficies, and of this but 5626·5984 square miles, inclusive of the islands of the river, are either in a state of cultivation, or fit for cultivation. The space actually under cultivation was found by M. Estève, according to M. Jacotin, to be 5469·8688 square miles; but the latter gentleman calculates that anciently 2735·0784 square miles more may have been cultivable, whereof much might still be reclaimed. His most important results are contained in the following table, which he gives in various measures of space, of which the square leagues of 25 to the degree of latitude are only here retained, while a column is added with the same sums in square geographical miles.

Nature of the Surface.

	Square Leagues of 25 to the Degree.	Square Geographical Miles.
1. Towns, villages, &c.	21·93	126·3168
2. Cultivated land, and land fit for cultivation	965·85	5563·2960
3. Uncultivated land which might be cultivated	224·87	1295·2512
4. Islands in the river	10·99	63·3024
5. Canals, with their banks, dikes, roads, &c.	36·19	208·4544
6. Ruins and rubbish, of ancient towns and monuments	4·89	28·1664
7. The river when at its height	47·71	274·8096
8. The lakes, ponds, and marshes, during the inundation	283·00	1630·0800
9. Sandy tracts, sea-shore, and hills, within the part of Egypt which can be inundated by the river, and distinct from the deserts	68·18	392·7168
Total	1663·61	9582·3936

In addition to these various kinds of surface, M. Jacotin estimates the desert tract between the limits of the fertile

[5] The square miles mentioned in these remarks are always geographical, whether this is specified or not.

Egypt.

soil and the foot of the mountains on either side of the Nile as equal to about 52 square leagues, or 299·52 square miles.

Mr Lane calculated the extent of the cultivated land in Egypt to be equal to 5500 square geographical miles, or rather more than one square degree and a half. "He made this calculation," says Mrs Poole, "from a list of all the towns and villages in Egypt, and the extent of cultivated land belonging to each. This list is appended to De Sacy's 'Abd Allatif.' It was made in the year of the Flight 777 (A.D. 1375-6); and may be rather underrated than the reverse. The estimate of M. Mengin shows that in 1821 the extent of the cultivated land was much less; but since that period, considerable tracts of waste land have been rendered fertile."[1] The near agreement of Mr Lane's calculation with those of M. Estève and Col. Jacotin, affords satisfactory evidence of the accuracy of the writer last mentioned. Mrs Poole's work was published in 1844, since which time the extent of the cultivable land can have varied but little.

Ancient divisions.

In the hieroglyphic inscriptions mention is made of "the two regions" of Egypt, and the kings of the whole land wear the crowns of Upper and Lower Egypt, although the country had been divided into more than two monarchies; all which shows that among its ancient inhabitants, in the earliest times, the natural division obtained. The upper country, or Upper Egypt, commenced above Memphis, comprising the narrow valley as far as the First Cataract; while the lower country, or Lower Egypt, was the plain containing the Delta, the cultivable land on each side thereof, and the few miles of territory which intervened between the point of the Delta and the southern part of Memphis. Near Memphis the mountains begin to recede, and the valley to open into the plain; and the commencement of the Delta was not anciently so far north of that city as it is at present north of its site. For the lesser divisions of Egypt under the Pharaohs, we must depend upon the statements of ancient writers, since satisfactory evidence has not been adduced on this matter from the hieroglyphic inscriptions. The first step, however, has recently been taken by Mr A. C. Harris of Alexandria, who has collected and published the hieroglyphical standards representing districts (whether nomes or toparchies), and ascertained that these standards have a geographical import.[2]

Diodorus Siculus relates that a king Sesôstris, whom he calls Sesoôsis, first divided Egypt into nomes, 36 in number;[3] and Strabo says that such was the ancient number of these provinces.[4] It will be seen, however, that the name Sesôstris was applied by the Greeks to more than one king, without any distinction; so that, if we admit that Diodorus is accurate, we cannot determine to which of the Pharaohs this relates; nor, since certain of these kings who were thus confounded reigned at distant periods, can we ascertain approximatively the time when nomes were instituted. It is not therefore possible to come to any certain conclusion as to the period before that of the Greek geographers. The following is a list of the more important nomes from Ptolemy, Pliny, Strabo, and the coins. In consequence of the changes that were occasioned by the increase in their number, and the confusion that is caused by different names having been applied to the same nome, no complete list could be given without large comments as to the disputed points. In the Delta and the rest of Lower Egypt, were the Mareôtic nome, the Alexandrian, the Metêlite, the Cabasite, the Saïte, the Prosôpite, the Sebennyte (which was separated latterly into two nomes), the Xoïte, the Athribite, the Mendesian, the Busirite, the Leontopolite, the Tanite, the Sethrôïte, the Arabian, the Bubastite, and the Heliopolite. The nomes of the Heptanomis were the Memphite, the Heracleopolite, the Arsinoïte, or Crocodilopolite, the Aphroditopolite, the Oxyrhynchite, the Cynopolite, the Hermopolite, and the Antinoïte. Of the Thebaïs the chief nomes were the Lycopolite, the Hypsêlite, the Aphroditopolite, the Antæopolite, the Panopolite, the Thinite, the Diospolite, the Tentyrite, the Coptite, the Theban, the Hermônthite, the Apollinopolite, and the Ombite. The Oasis of Jupiter Ammon forms a separate nome in Pliny's list, and the other two oases, the "Great" and "Little," were included in the Antinoïte nome, according to Ptolemy. Strabo assigns ten nomes to the Delta, the same number to the Thebaïs, and sixteen to the intermediate space; but it is not clear that he refers to his own times, and the text seems inaccurate, and the number sixteen should rather be assigned to the nomes of the Delta. Ptolemy enumerates 44 nomes, and Pliny 46. Subsequently, however, they increased to about 58 or 56, 35 or 33 in Lower Egypt, 8 in the Heptanomis, and 15 in the Thebaïs.[5]

The whole country in the time of the earlier Cæsars was divided into the Delta, Heptanomis, and Thebaïs. The first of these comprehended nothing beyond its natural limits, excepting certain portions of land to the east and west; the second, called Heptanomis, because it originally comprised seven nomes, commenced at the point of the Delta and extended southwards to the Thebaïca Phylace; and the third, the Thebaïs, reached thence to the First Cataract. About the close of the fourth century Lower Egypt was further divided into four provinces, Augustamnica Prima and Secunda, and Ægyptus Prima and Secunda, and the Heptanomis was called Arcadia from the Emperor Arcadius, while Upper Egypt was divided into Upper and Lower Thebaïs.

Modern divisions.

The following is a list of the modern divisions and provinces:—El-Akâleem El-Bahreeyeh, or the northern provinces, comprehending the Gharbeeyeh, the province of Er-Rasheed, or Rosetta, the Boheyreh, the province of El-Mansooreh, the Manoofeeyeh, the province of Ed-Dimyât, or Damietta, the Sharkeeyeh, the Kalyoobeeyeh, and the province of El-Geezeh. El-Akâleem El-Wustâneeyeh, or the middle provinces, containing the province of Atfeeh, the Feiyoom, the province of Benee-Suweyf, and that of El-Minyeh. El-Akâleem El-Kibleeyeh, or the southern provinces, having three divisions, the province of Asyoot, that of Girgeh, and that of Kinè. This is the manner in which the country was officially divided at the time of the French invasion, and the same division popularly obtains at the present day. Under the Memlook Sultâns of the Bahree Dynasty, we find Egypt divided into somewhat smaller provinces, whereof the less important were afterwards merged in those adjoining them, and the later system was thus formed. By Mohammad 'Alee Páshá a new division was organized into mudeerliks, or districts governed by a mudeer, of which Lower Egypt, including a small portion of Middle Egypt, contained four, and Middle and Upper Egypt three.[6] In consequence of these circumstances it will be easily understood that much confusion prevails respecting the modern divisions of the country.

General appearance.

The general appearance of Egypt is remarkably uniform. The Delta is a level plain richly cultivated, and varied alone by the lofty dark-brown mounds of ancient cities, and the

[1] *Englishwoman in Egypt*, vol. i., p. 85. M. Jomard in the *Description de l'Egypte* (ix., p. 110), calculates the land mentioned in the list given by De Sacy, to be 952·1 square leagues, or 5592·96 square miles. Mr Lane has preferred giving a round sum, for the reason doubtless that accuracy is not to be expected in a list of the kind.

Egypt.

villages in groves of palm-trees, standing on mounds often if not always ancient. We sometimes see groves of palm-trees besides those around the villages, but other trees are, except in some parts, rare. In Upper Egypt the valley is in as rich a state of cultivation, but very narrow and bounded by mountains of no great height, which hem it into a confined space. The mountains seem like cliffs from the river, but are rarely very steep. They constitute the edge of the desert on either side of the valley, which appears as though it had been cut through a rocky table-land, for they rarely take the form of peaks. Sometimes they approach the river in bold promontories, and at others are divided by a valley with the bed of a torrent that flows only at very distant intervals. The features of the country therefore vary very little, nor is there great difference in the colour. The bright green of the fields, however, the reddish-brown or dull green colour of the great river, the tints of the bare yellow rocks, and the deep blue of the sky, always form a pleasant view, and often one of great beauty.

Climate and meteorology.

The climate of Egypt, being remarkably equable, is healthy[1] to those who can bear great heat, and who avoid the unwholesome tracts of the country. Europeans, exclusive of the Turks, generally hold a contrary opinion to this; but it should be remembered that Alexandria, where most of them reside, is situate on a salt marsh, and that those born in cold climates are generally found to be unfit to support great heat, more especially if they persist in a mode of life which, though not prejudicial in a cold climate, is the surest means of destroying the constitution in a hot one. The English physician at Cairo, Dr Abbott, who has resided in Egypt several years, but is also acquainted with many other countries, considers that the climate is the finest in the world; and he does not stand alone in thinking thus.

The atmosphere is remarkably dry and clear, except on the sea-coast; and even the humidity, which is the inevitable consequence of the spreading of the inundation, is scarcely felt except in its usually rendering the heat more oppressive. Sometimes a white fog very dense and cold rises from the river in the morning, but it is of rare occurrence and short duration. The heat is extreme during a great part of the year, but it is chiefly felt when accompanied by the hot winds of spring, and the sultry calm of autumn, after the Nile has overspread the lands. The winter is often comparatively severe in its cold, especially as the domestic architecture is calculated to protect rather from heat than cold. "The general height of the thermometer in the depth of winter in Lower Egypt, in the afternoon and in the shade, is from 50° to 60°: in the hottest season it is from 90° to 100°; and about ten degrees higher in the southern parts of Upper Egypt."[2]

On the coast of the Mediterranean rain is frequent, but in other parts of Egypt very unusual. At Cairo there is generally one heavy storm in the winter, and a shower or two besides, while at Thebes a storm occurs but once in about four years, and light rain almost as rarely.

The wind most frequently blows from the north-west, north, or north-east, but particularly from the first direction. The proportionate prevalence of these winds to those from all the other quarters, in the year, is about 8 to 3; but to those from the south, south-east, and south-west, about 6 to 1.[3] The northerly winds are the famous Etesian winds of the ancients, which enable boats constantly to ascend the Nile against its strong and rapid current. They also cool the temperature during the summer months. The southerly winds are often very violent,[4] and in the spring and summer, especially in April and May, hot sand-winds sometimes blow from the south, greatly raising the temperature, and causing especial suffering to Europeans. The famous Simoom, properly called Samoom, is a much more violent hot sand-wind, which is more usual in the desert than in the cultivated tracts, but in either, occurring only at long intervals. It is a kind of hurricane, most painful to experience, and injurious in its effects.[5] The Zóba'ah is a common but remarkable phenomenon. It is a very lofty whirlwind of sand resembling a pillar, which moves with great velocity, and when crossing the Nile frequently capsizes any boat which may be in its way, and of which the main sheet is tied, through the carelessness of the boatmen, instead of being held. Mr Lane measured some with a sextant and found them to be between five and seven hundred feet in height, and one to have an altitude of seven hundred and fifty feet.[6]

One of the most interesting phenomena of Egypt is the mirage, which is frequently witnessed both in the desert and in the waste tracts of uncultivated soil near the Mediterranean; and it is often so truthful in its appearance that one finds it difficult to recognise the illusion.

Diseases.

Notwithstanding the fineness of the climate, the stranger who visits Egypt is struck by the signs which he sees everywhere of the prevalence of many serious diseases, while he may be a witness of calamitous visits of the plague or the cholera. Yet he should remember the poverty of the great mass of the inhabitants, and their insufficient food, the ignorance of the native medical practitioners, the false system of many of the foreigners established in the country, and the reluctance of the natives to take medical advice. Ophthalmia is frequently followed by blindness if not treated, and dysentery, without the aid of physic, still oftener terminates fatally; so that there is no reason to wonder at one's frequently meeting blind persons, and hearing of deaths from dysentery.

The plague may be regarded as the most remarkable disease of Egypt. Plagues are recorded by Manetho to have occurred in the reigns of two of the most ancient kings,[7] and this malady is evidently alluded to in the Bible as peculiarly Egyptian.[8] It has not, however, broken out since the year 1843, when there was a plague of a comparatively insignificant character so far as the mortality was concerned. In 1835 there was a plague of extreme severity, by which there died of the inhabitants of Cairo a number equal to the whole adult male population.[9] There having been no outbreak since 1843, whereas ordinarily there would have been several before the present year (1855), has been attributed to the sanitary measures of the Egyptian government. That government doubtless deserves great credit for its exertions in this matter; but all such efforts would have as yet produced but little result were it not for the constant extreme dryness of the climate, and the powerful heat of the sun during a great part of the year.

The plague is not confined to Egypt, but appears on the east and south coasts of the Mediterranean, and part of the north coast, and sometimes pursues a similar course to the cholera in advancing steadily from place to place. In Egypt it usually first appears at Alexandria in the winter or spring, and if the earliest cases occur towards the close of the year, one may be sure of a plague of great severity and long continuance. At first the cases are generally few, but they gradually increase, and in the hottest weather attain their maximum. The disease is not long in travelling from Alexandria to Cairo, but it rarely ascends much higher

Egypt.

up the river, and has seldom been known at Thebes in modern times. Many medical writers have denied the contagious character of the plague; in particular, Clot-Bey, a French physician, who was long chief medical officer of the Egyptian government, and who published a treatise on this disease;[1] yet it is impossible to deny the positive evidence of the senses, showing not only that the plague is contagious, but that it is so in the highest degree. The efficacy of quarantine is alone a strong argument in favour of those who believe in its contagious character; but the distinct fact, for example, of persons having taken the disease after wearing the clothes of those who had died of it, in circumstances the most conclusive, can hardly be rejected.

Dysentery is an extremely common malady, and causes very considerable mortality. It may usually be traced to a careless course of diet, and especially to the eating of crude vegetables, and unripe or unwholesome food, and the drinking brackish water. Mr Lane (in the *Modern Egyptians*) has made public a mode of treatment which has been attended with extraordinary success.[2]

Asiatic cholera has visited Egypt in its westward course on the occasions in which it has appeared in Europe, excepting the last visitation; and it is remarkable that after each of the two former occasions, the epidemic appeared a second time, but with far less destructive results. At each of these times the mortality was considerable, nearly 200,000 having perished in all Egypt, according to the government reports, which were probably below the truth, in 1848.

Among the diseases most dreaded by the European residents, or, to use the expression of the natives, the Franks, is the liver-complaint. Those, however, who are moderate in the use of intoxicating drinks, or who abstain from them altogether, either escape this disease, or suffer from it in a comparatively mild form. Hæmorrhoids and herniæ are among the most ordinary maladies.

Cutaneous disorders have been esteemed from ancient times among the curses of Egypt. Leprosy is well known but not common, unlike elephantiasis, which in more than one form has numerous victims. Smallpox was formerly very severe, but its virulence has been checked by the use of vaccination. There are various other diseases of lesser importance, the most remarkable being the so-called guinea-worm, which, however, is perhaps not indigenous.

Of the diseases of the eye, ophthalmia is the most formidable from its prevalence and malignant character; yet perhaps no malady is more amenable to treatment if promptly commenced. Where the predisposition exists, a slight cause, such as the irritation caused by a grain of dust or sand, is sufficient to produce an inflammation, which, if allowed to increase, inflicts a lasting injury if it do not produce blindness. For this disease also Mr Lane has published a very efficacious mode of treatment.[3]

Clot-Bey affirms that pulmonary consumption is extremely rare among the native inhabitants;[4] yet another physician of ability has asserted, though not in print, that he had met with not a few cases in a short practice. The opinion of the former is corroborated *primâ facie*, by the circumstance that the Romans sent their consumptive patients to Egypt, and that modern European physicians have adopted the same course; yet the ill success of this change argues unfavourably for the climate of Egypt for persons thus afflicted. Its effect is not that of the climate of Madeira, and the patient rarely improves. A residence in the desert, however, a mile or two from Cairo, under canvas, would probably have a beneficial result in cases of incipient consumption. Asthma and bronchitis are among the common disorders.

The occurrence of coup-de-soleil is not unusual, but it is rarely attended with fatal results. Madness is common, but it generally assumes the milder form of idiocy. Maniacs alone are confined: idiots are regarded with much respect as saints, and it is probable that some persons feign idiocy to become objects of popular veneration, supported by alms given ungrudgingly. One of the Memlook Sultáns, Kaláoon, after the example of Saláh-ed-Deen or Saladin,[5] founded a madhouse or máristán at Cairo, which yet remains,[6] but in a grievously neglected state. Of late it has been found necessary to remove the patients thence to a modern hospital.

Nervous affections are uncommon, probably owing to the calm life which the inhabitants lead. Rheumatism is of more usual occurrence; but gout is, according to Clot-Bey, unknown.[7] It is very remarkable that hydrophobia is also unknown in Egypt. Although ownerless dogs are very numerous in Cairo and the smaller towns, and the heat of summer is so great, there is no recorded instance of rabies; yet Clot-Bey is probably in error when he says that it has not been observed at any period in that country,[8] for the formularies of the Coptic church contain a prayer to be used for a person afflicted with hydrophobia,[9] and such a prayer is not likely to have been derived from a foreign source.[10]

Geology.

In considering the geology of Egypt, its deserts claim our first notice. By a desert is generally understood a wide plain of shifting sand; but this is usually an erroneous description of such a tract, and especially inapplicable to the deserts which border the valley of the Nile. These are raised mountain regions, the surface of which is often covered with sand, débris, and pebbles, intersected by valleys, and diversified, in the case of the western desert, by some oases.

On both sides of the Nile the mountains are limestone, until a little above Thebes, where the sandstone commences. At the First Cataract red granite and other primitive rocks burst through the sandstone beneath the bed of the Nile, and for a considerable space on the east, obstructing the course of the river by numerous small islands and rocks, and thus forming the rapids. In several places, chiefly on the eastern side, bold promontories or steep mountains approach the river, and sometimes reach it. They are always utterly devoid of vegetation, and, except the granite, generally of a yellowish or reddish colour, though in some places they are greyish. Near the cataracts the sandstone mountains are partially covered with a bright yellow sand in drifts. The mountains on both sides near the river are usually about 300 feet in height, and rarely much loftier. The highest point on the western bank at Thebes is four times that altitude. If one leaves the river and ascends the mountains, he finds a great rocky tract before him, the only easy paths through which are along valleys often very winding. The eastern desert gradually rises until about midway between the Nile and the Red Sea, where primitive rocks burst through the later formation, and the loftiest of them, a granite mountain called Gebel-Ghâreb (*cir.* Lat. 28.) at-

9 This is stated on the authority of the Rev. J. R. T. Lieder of Cairo, who has been long engaged in endeavouring to educate the Copts, and has succeeded in removing many of their prejudices, especially against Protestants. While occupied in this labour, he has collected a valuable amount of information respecting the ancient and remarkable church to which this remnant of the old inhabitants of Egypt belong.
10 For an account of the diseases of Egypt, see Clot-Bey's two works *Aperçu Général* and *De la Peste*, and *Desc. de l'Egypte*, tom. xiii., p. 29 *et seqq.*

Egypt.

tains the height of about 6000 feet. In this portion of the desert are porphyry, breccia, and basalt rocks, which were much prized by the ancient inhabitants for purposes of architecture and sculpture. The western desert is of a lower elevation, and is principally remarkable for its oases, which are deep valleys containing alluvial soil, but they are little productive except in dates. Their beauty and fertility has been much, though naturally, exaggerated. Notwithstanding the inequalities of their surface, it is evident that these deserts gradually rise towards the Red Sea, attaining their greatest height in the peninsula of Sinai, which is but a continuation of the same tract.

The most remarkable geological change which has been observed to have taken place in Egypt, and which is still in operation, is the depression of the northern shore and the corresponding elevation of the southern part of the isthmus of Suez. The consequence of this change of level has been the ruin of places on the shore of the Mediterranean, and the extension of the salt-marshes, and at the same time the drying up of a considerable part of the northernmost portion of the Gulf of Suez. It is very interesting to find this latter result predicted in the Scriptures at a time when it could not have been humanly foreseen. Thus Isaiah prophesied, "The waters shall fail from the sea, and the river shall be wasted and dried up;"[1] and, in another place, "The Lord shall utterly destroy the tongue of the Egyptain sea; and with his mighty wind shall he shake his hand over the river, and shall smite it in the seven streams, and make [men] go over dryshod" [Heb., *in shoes*]. In the latter passage,[2] "the river" may mean Euphrates, and instead of "in the seven streams," we may read "into seven streams;"[3] but the former passage, as well as another,[4] are sufficient to show that a diminution of the streams of the Nile was also prophesied, which likewise has been remarkably fulfilled. The bed of the Red Sea may be traced for a course of several miles north of Suez, which now stands at the head of its western gulf; and places considerably north of that town were on the coast within the historical period. Indeed, the change appears to have occurred chiefly, if not wholly, during that time.

The form of the plain and valley inclosed by the deserts and mountains is remarkably regular. In Lower Egypt the cultivable land little exceeds the limits of the ancient Delta, but considerably those of the space between the two remaining branches of the Nile. The northern coast is protected by shoals and a low range of sand-hills. To the south of these are extensive salt-marshes and lakes, or waste tracts, and then the cultivable land commences. The form of the valley, or Upper Egypt, may be more accurately described. For the first 70 miles above Cairo, by the course of the river, the valley is nearly north and south, until it takes a westerly direction, which it maintains for about the same distance. It then bends in an easterly course for a few miles, and again runs north and south for a longer distance, until, about 60 miles higher than the point where it turned towards the east, it again takes that direction, which is first E.S.E., then S.E., then due E., and at last a little to the N. of E. After this easterly course of near 200 miles, the valley becomes N. and S. for about 30 miles; it then turns to the W. for about 20 miles, and to the E. for about 50, when it again assumes a southerly direction for the remaining 60 miles below the First Cataract, the boundary of the country. The mountains and desert on the western side throughout Upper Egypt (or Middle and Upper), that is above Cairo, are generally further from the river than those on the eastern, which frequently reach to the water's edge. The difference is most remarkable as far as the town of Farshoot, which is by the course of the river about 350 miles above Cairo, and about 70 miles below Thebes. Near Farshoot commences a continuous series of canals, which flow parallel to the Nile, and near the Libyan chain, until they terminate in Lower Egypt, not far north of Cairo. South of Farshoot, the western mountains gradually approach the Nile; until, halfway between Thebes and the First Cataract, the cultivable soil is equally narrow on each bank; for, with the exception of a tract about 70 miles in length, commencing a little above Farshoot, and terminating a little above Thebes, the mountains and deserts on the eastern bank are very near the river throughout Upper Egypt. The greatest breadth of the cultivable land, all of which is not now cultivated, on the western bank seldom exceeds about 8 or 10 miles, and on the eastern bank, about 3 miles, but it is usually much narrower.

There is in Upper Egypt one striking deviation from the uniform character of the country. About 70 miles above Cairo, by the course of the Nile, an opening in the Libyan range leads to a kind of oasis, the Feiyoom, a fertile tract, lying in a hollow of the desert, and having at its further extremity a considerable lake of brackish water.

Names of Nile.

In the hieroglyphic inscriptions, the Nile receives the name of Hapimou, or the "abyss of waters,"[5] under which it was worshipped as a god. This divinity is represented as a stout man having woman's breasts, and sometimes painted red, but at others blue, to indicate the river at the season of its rise and during the rest of the year, or High and Low Nile.[6] The names of the Nile in Coptic are *φιαρο* or "the river," which was probably likewise an ancient Egyptain name, and its variations, and *πιαυτης*. Other supposed Coptic names rest upon doubtful authority.

We find in the Bible three names of the Nile. It is frequently called נְהַר מִצְרַיִם, or "the river of Egypt."[7] The appellation יְאוֹר, or יְאֹר, and its plural, is similar to this, and is probably of Egyptian origin. The Nile also receives the name of נַחַל, or נַחַל מִצְרַיִם—that is, if the word נַחַל be a proper name—Nahal, and Nahal-Mizraim; or, if it bear its ordinary Hebrew signification, "the brook," and "the brook of Egypt." Hence a difference of opinion has obtained respecting this name, some maintaining that it was a name of the Nile, while others concluded that it applied to a mountain torrent, which is usually dry, on the border of Egypt and Palestine, sometimes called the river of Egypt. In parallel passages, however, "the river of Egypt" and "the Nahal of Egypt" are used synonymously,[8] and almost certainly, also, the latter and the name Shihor, which is undoubtedly a name of the Nile.[9] It becomes a question, then, whether Nahal is to be taken in its ordinary Hebrew signification, or as a proper name of the river, and the origin of the Greek Νεῖλος. That it usually signifies a brook when applied to a stream cannot be denied, but its proper and first meaning is a valley, and thence a mountain-torrent. The Arabs, in like manner, have often used the word "wâdee," properly signifying "a valley," to designate rivers, because mountain-torrents in the valleys of Arabia are the streams to which the natives are accustomed: hence the names of several Spanish rivers commence with this word, as the Guadalquivir, a corruption of the Arab name, El-Wâdee el-Kebeer, or "the great river." It is not unreasonable, therefore, to suppose Nahal not to be a proper name. On the other hand, it may be argued that it is scarcely likely that two such similar appellations as Nehar-Mizraim and Nahal-Mizraim would be employed to designate the same stream, particularly as they ordinarily

9 Josh. xiii. 3.

bear different significations; that the Arabs have the parallel appellation, Neel-Misr, or the Nile of Egypt; and that Nahal bears a resemblance to Νεῖλος which can hardly be accidental. The name שִׁיחוֹר, *Shihor*, which occurs in the Bible, as already noticed, is derived from שָׁחַר, "to be black," and signifies turbid and black.

The proper name of this river in Greek is Νεῖλος, by which it is known among the Arabs, who call it النِّيل *En-Neel*, the Nile, or نِيل مِصْر *Neel-Misr*, the Nile of Egypt. A famous Arab lexicographer gives the following explanation of this word:—"النِّيلُ is the river (lit. the inundation) of Egypt: Es-Saghânee says—'But as to the نِيل [indigo] with which one dyes, it is an Indian word Arabicised.'"[1] As the Hebrew word Shihor signifies black or turbid—and, with that signification, properly applies to the river during the inundation—it is very remarkable to find a name properly signifying the Nile during the inundation, to be the same as that of the dye indigo. It should be remembered also that the Low Nile was painted blue by the ancient Egyptians. The river is turbid and reddish throughout the year, and turns green about the time when the signs of rising commence, but not long afterwards becomes red and particularly turbid. Not to extend these remarks further, and to show more clearly the connection between the different names of the Nile mentioned above and others, a comparative list is here appended.

Hebrew.	Arabic.	Greek.	Latin.
Nahar-Mizraim		Αἴγυπτος ποταμὸς	
Nahal-Mizraim	Neel-Misr		
Nahal	Neel	Νεῖλος	Nilus
Shihor		Μέλας	Melo
	Bahr (Sea)	Ὠκεανὸς ?	

The Gihon, which is mentioned as one of the four rivers which arose in Eden, has been supposed by early commentators, as well as by certain modern critics, to be identical with the Nile. This opinion, however, is irreconcilable with the position of the other rivers, two of which are indubitably the Tigris and the Euphrates, and the third, probably the Phasis.

Source. The present article is not the place in which to examine the various opinions which have obtained respecting the source of the Nile. It is enough to say, that the interesting discoveries by Dr Krapf and Mr Rebmann, the missionaries stationed at Mombas, leave no room to doubt that the Bahr el-Abyad, or White Nile, flows from snowy mountains south of the equator. These must be the Mountain or Mountains of the Moon spoken of by Ptolemy and the Arabian geographers, and so called, according to Aristotle, from their whiteness.[2] The Arabs generally have placed the source of the river considerably south of the equator; and the errors of our modern European geographers must be ascribed to the Greeks. For further details, see the article NILE.

Change in level. A remarkable change has been ascertained to have occurred in the level of the Nile above Gebel-es-Silsileh (the ancient Silsilis, more than 80 miles south of Thebes), and throughout a considerable portion of Nubia. Indications of this change were first observed by Dr Lepsius, who discovered hieroglyphic inscriptions on rocks at Semneh, not far above the Second Cataract, showing that the river attained a much higher level about 2000 years before the Christian era than it does now. Sir Gardner Wilkinson pursued the inquiry in a paper read before the Royal Society of Literature, and published in their Transactions,[3] wherein he argues that the cause of this alteration must have been the bursting through of a barrier at Silsilis, where the low mountains confine the river to a narrow channel. There must have been at this place, therefore, an ancient fall of far more importance than the First Cataract, and those above it throughout Nubia; and from it may have arisen the accounts in classic writers of the greatness of the cataracts of the Nile, which are wholly inapplicable to the present First Cataract. This change seems to have been already complete about the beginning of the fourteenth century before our era, and we cannot tell if it had not been effected considerably earlier. All that is known for certain is, that it took place after the middle of the twentieth century B.C., and before the later date first mentioned. Its result has been to place the cultivable soil of a great portion of Nubia beyond the reach of the inundation, so that it is irrigated alone by water-wheels.

Water and deposits. The water of the Nile differs considerably in appearance and purity at various seasons of the year. A little after midsummer it becomes very turbid, and not long afterwards it assumes a green colour for more than a fortnight, owing to the quantity of vegetable matter which it brings down from its upper course. It then resumes its turbid character for the period of the rise, and retains it, though in a less degree, for the remaining portion of the year, until the following midsummer. The water is extremely sweet, particularly if drunk in its turbid state, and is easily filtered through porous jars manufactured in the country. Too careful a filtration destroys its peculiar flavour, and diminishes its excellence. It is very wholesome, except during the short period at which it is green; and the inhabitants of Egypt hold it in such high esteem, that they say, that he who has once drunk of the water of the Nile must return to drink of it again. Its turbid appearance, particularly during the rise and inundation, is owing to the presence of large quantities of earthy matter, which are annually deposited. The deposit, or mud of the Nile, has been thus analysed by M. Regnault.[4] The specimen was dry, and taken from a canal which conducted the waters of the inundation. He obtained the following results:

Water	·11
Carbon	·09
Oxide of iron	·06
Silica	·04
Carbonate of magnesia	·04
Carbonate of lime	·18
Alumen	·48
	1·00

M. Regnault remarks that the quantities of silica and alumen vary according to the places whence the mud is taken. "On the banks of the Nile the mud contains much sand; and, when it is carried by the waters of the inundation to distant tracts, it loses on the way a quantity of sand proportionate to its distance from the river; so that, when this distance is very considerable, one finds the argillaceous matter almost pure: thus the soil of Egypt presents argillaceous matter in those different states of purity which the arts require."[5]

Rise and inundation The Nile shows the first signs of rising in Egypt about the time of the summer solstice. At Khartoom, where the White River and the Blue River join, the commencement of the increase is observed early in April.[6] The slowness of the rise at first causes this difference. Usually the regular increase does not commence in Egypt until some days after

[1] The Misbâh of El-Feiyoomee.

[2] The incidental allusion in Aristotle is very valuable, if referring to these mountains, since it has been suggested that the mention in Ptolemy is an interpolation, because it was supposed to be unsupported by any other ancient writer. May not the story Herodotus tells of the source of the Nile from two mountains be an incorrect version of a true statement? (ii. 28).

[5] *Description de l'Egypte*, tom. xx., pp. 163-4.

[6] Clot-Bey, tom i., pp. 36, 37.

the summer solstice, and the inundation begins about two months after that solstice. The river attains its greatest height at, or not long after, the autumnal equinox, and then, falling more slowly than it had risen, sinks to its lowest point at the end of nine months, when it remains stationary for a few days, until it begins again to increase. The inundation continues rather longer than it naturally would do, because the waters are retained for some time upon the lands by closing the mouths of the canals.[1] The river's banks being a little higher than the rest of the cultivable soil, the water is conveyed by canals or cuttings, and does not pour over the banks.

The inundations vary considerably, and, by either failing or rising to too great a height, cause much damage and distress. In the great French Description of Egypt, there is a table of sixty-six inundations, whereof eleven were very high, thirty good, sixteen feeble, and nine insufficient. This table was taken from the official records of the Nilometer on the Island of Er-Rōdah, near Cairo, and comprehends the inundations of the years A.H. 1150–1215, that is, A.D. 1737–1800.[2]

The Nile rises about 40 feet at the First Cataract, about 36 at Thebes, about 25 at Cairo, and about 4 at the Rosetta and Damietta mouths of the Nile, during a good inundation.[3] When it is said, however, that the river has attained to a certain height in feet or cubits, the height at the Nilometer of Er-Rōdah above-mentioned is meant; and by ancient writers, that of the river at Memphis, which was situated on the western bank, a little higher than Er-Rōdah. If the river do not attain a greater height than 18 or 20 feet, the rise is scanty; if only 2 or 4 feet more, insufficient; if it attain to 24 feet, or a greater height, not exceeding 27 feet, the inundation is good; but a higher rise must be characterized as a destructive flood.[4] Sometimes the inundation has failed altogether; as for seven years (A.H. 457) in the reign of the Fátimee Khaleefeh El-Mustansir bi-llāh, when there was a seven-years famine;[5] and low inundations always cause dearths. Excessive inundations, on the other hand, produce, or at least foster, the plague and murrain; so that a variation of a few feet is productive of the most serious consequences.

Current and volume of water.

The current, when at the lowest, has been estimated at about 2 feet a second, or a mile and a third in the hour, and at about 3 miles an hour during its height. The volume of water which the Nile pours into the Mediterranean in 24 hours, is as follows, according to M. Linant, an engineer in the employ of the Egyptian government:[6]—

		Cubic Mètres.
During the Low Nile,	by the Rosetta Branch,	79,532,551,728
	by the Damietta Branch,	71,033,840,640
		150,566,392,368
During the High Nile,	by the Rosetta Branch,	478,317,838,960
	by the Damietta Branch,	227,196,828,480
		705,514,667,440

Increase of soil by deposit.

Although the water is so abundantly charged with alluvium throughout the year, and especially during the inundation, the annual deposit by the river, except under extraordinary circumstances, is very much smaller than would be conjectured by any one unacquainted with researches into subjects of this nature. Various opinions have obtained as to the exact deposit left in a century on the land, but the inquirers have not usually differed in their results above an inch. If, however, we compare the quantity of deposit on certain very ancient structures, whereof we know the date, we shall find that the amount has materially differed in various places. Such differences are the natural results of irregularities in the river's course, of the strength or weakness of the current at particular places, of the nature of the country, and many other disturbing causes, from which we might have expected even greater variations. The ordinary average rate of the increase of the soil of Egypt may however be stated as about four inches and a half in a century.[7]

The cultivable land of Egypt must be regarded as wholly the deposit of the Nile, but it is vain to attempt a calculation of the period at which this process commenced, since we cannot conclude that the same ratio has always obtained, and we must suppose that the causes then in operation were very different from those which now regulate the phenomenon.

Cultivable soil.

From the table of the superficies of Egypt, it will be seen that the cultivable soil occupies only 5626 square miles, and that which might be cultivated only 1295 square miles, altogether 6921 square miles, or somewhat more than two-thirds of the whole space included between the deserts; but the quantity actually under cultivation does not exceed 5469 or 5500 square miles, or six-elevenths of the entire surface. This was not always so, and the deficiency of the population is the principal cause that near one-half of the soil which might possibly be brought into a state of culture is left uncultivated.

Throughout Egypt the cultivable soil does not present any very great difference, being always the deposit of the river; it contains, however, more sand near the river than at a distance from it. Towards the Mediterranean, its quality is injured by the salt with which the air is impregnated, and therefore it is not so favourable to vegetation. This, however, does not usually extend far south of the sea or the salt-marshes which intervene for the most part between it and the land. In Lower Egypt we find the greater portion of the neglected tracts principally to the E. and W. of the modern Delta, and in its northern portion. In Upper Egypt the narrowness of the valley, and the more numerous population, preserve the country in a better state of cultivation, and the soil is somewhat richer. The largest uncultivated tracts lie on the western bank, where the valley is broadest, and in places where the great canal running parallel to the Nile has fallen into a neglected condition. It may not be uninteresting to endeavour to trace the causes which have produced this change in Egypt.

Ancient prosperity of Egypt, and its decline.

Although some of the accounts of classic writers may be deemed exaggerated when they speak of the population and prosperity of Egypt in ancient times, we cannot accuse them of errors, except in the numbers of cities and villages, and of the inhabitants of the country; for the monuments show us how rich was Egypt under native rulers, and indicate to what causes this condition may reasonably be assigned. From the time at which the Great Pyramid was built, to the Persian invasion, a period of not much less than 2000 years, the population of Egypt and its extent of cultivated land far exceeded what they are in the present day. The country does not seem to have been over-populated; and many causes conduced to prevent this, such as the serious wars in which the Pharaohs engaged, the formation of colonies, and the like. The conquest by Cambyses, and the subsequent long and desolating struggle with the Persians, inflicted a severe blow on the interests of the country. Under the Macedonians it recovered much of its former prosperity; and when the Romans held Egypt, it was one of their most productive provinces, and the granary

[6] Clot-Bey, tom. i., p. 41.
[7] This is Mr Lane's calculation. M. Girard, in the *Description de l'Egypte*, makes it "very nearly" 126 millimetres, that is in English inches 4·96071954. For a remarkable instance of rapid deposit see the *Englishwoman in Egypt*, vol. i., p. 132.

Egypt. of the empire. During the period of their rule, or for nearly seven centuries, various causes contributed to the decline of the population, but they were all of a political character. The chief of these were the contests of rival emperors, the occasional attempts of the natives to regain their independence, the incursions of savage tribes whom the Romans often had not power enough to repulse, notwithstanding that Egypt was in part protected by German mercenaries, until they had inflicted much loss on the inhabitants; and lastly, the religious struggles, first the persecutions of the Christians by the idolaters, and then the differences of Christian sects. After the Muslim conquest, this decay continued almost uninterruptedly until the accession of the Fâtimees; but from that time until the Turkish invasion, although foreign wars certainly diminished the population, the kings of that and the succeeding independent dynasties generally governed the country with a regard for its best interests, and cannot be accused of the tyranny and misrule of which the Turkish pâshâs have been guilty To them must be attributed the present miserable condition of Egypt. The great evil then is an insufficient population, and their consequent inability to cultivate the whole of the land fit for culture.

Physical causes have been assigned to account for what is in the main simply traceable to political ones. The geological change producing the elevation of the tract north of the head of the Gulf of Suez, and the depression of the north coast of Egypt has considerably diminished the cultivable soil in the Delta, by increasing the salt lakes and marshes which occupy its southern portion. There is, however, no greater fallacy than to suppose that the sands of the deserts have done injury by encroaching on the alluvial tracts, and that once fertile regions are buried beneath them. In some places they have undoubtedly encroached upon the valley or plain; but the deposit of the Nile has been constantly, and in almost every part of the country, encroaching upon the deserts, and thus diminishing their extent. It is neglect which might easily be remedied, that has permitted the sands thus to cover the soil where there have been no labourers to cultivate it. Above Gebel-es-Silsileh (Silsilis), in Upper Egypt, the change in the level of the Nile has placed fertile tracts almost wholly beyond the reach of the inundation, and thus made agriculture very laborious, but this is only for the space of about 40 miles in Egypt, where the extent of cultivated soil must always have been small on account of the narrowness of the valley. The failure of five of the seven branches of the Nile is partly to be charged to the neglect of the inhabitants, since all might have been maintained as constantly running canals; and the decay of the great canal which runs parallel to the Nile throughout the chief part of Upper Egypt is traceable to the same cause.

Projects for restoring its prosperity.

Various projects have been undertaken of late to better the condition of Egypt. The most promising of these was the construction of a barrage across both branches of the Nile at the point of the Delta, in order to regulate the inundation, and thus to render the country more fertile and easy of cultivation. This great engineering work was commenced under the government of Mohammad 'Alee, and continued under that of Ibraheem Pâshâ. Abbâs Pâshâ ordered it to cease; but it is said that Sa'eed Pâshâ, the present governor (Jan. 1855), intends to complete it. There is no doubt that, if successful, this barrage would produce the most happy results; but many other changes must take place before we can hope that Egypt will begin to recover anything of its ancient prosperity. A better government, and the placing the commerce of the country in native hands, would do much to effect this desirable result; but as far as we can judge, such a reform is unlikely. The pashalic will cease at the expiration of the present treaty with the Porte to be hereditary, and the governors will have no desire but to extract as much wealth as they can from their unfortunate province. The destiny of Egypt may indeed be different, but this is not the place in which to discuss the Oriental Question.

Agriculture under the Pharaohs.

Under the Pharaohs Egypt was an agricultural country, and both commerce and manufactures were comparatively unimportant. They judged rightly, that the main energies of the people should be expended in turning to the best account a soil of unexcelled richness, annually watered and renewed by the river. From the sculptures and paintings of the tombs, we form a clear idea of the agriculture of the ancient Egyptians, while the Scriptures and the classical writers give us information respecting the tenure of land, and the laws affecting the cultivators.

From the representations on the walls of the tombs, we learn what especial attention the great proprietors of land paid to the processes of agriculture. We see them constantly overseeing the labourers, and thus watching the interests of their lands; and this indicates one of the causes of the national prosperity of those times. The Egyptians were especially anxious to have a sufficient supply of water, both to draw the waters of the Nile upon those tracts which were not above their level at different periods, and to raise them by manual labour to the higher portions of the land. To effect the former object, they displayed great mechanical skill, as well as in the construction of dams and dikes, to retain the waters upon the lands; but for the latter they seem to have been contented with the rudest contrivances. Indeed, we know of but two methods that were employed in raising water, the use of the simple machine called in the present day the shâdoof, and buckets carried by men. The shâdoof is still employed, and is of the same form as that used by the ancient Egyptians. It consists of a pole resting upon a beam placed across two columns of brick or mud, and having at one extremity a weight, and at the other a rude bowl-shaped bucket suspended by a stick.[1] A man stands beneath it, and pulling down the bucket to the water, raises it again, assisted by the weight.

Immediately after the water of the inundation had subsided, the land was ploughed or broken up by the hoe, and sown, the seed being sometimes trodden in by goats driven over the field for the purpose.[2] Wheat being the most important of the field produce, we find the various agricultural processes connected with it frequently represented. Besides the ploughing and sowing, the harvest is depicted, the reapers cutting the wheat just below the ear, the ears being carried in nets or baskets by men or on asses to the thrashing-floor, where they were thrashed by oxen or cows.[3] Sometimes the wheat was bound in sheaves.[4] The same or similar processes with reference to other kinds of grain are pourtrayed in the tombs, wherein we find also curious representations of the vineyards and gardens. The vineyard was not the least valuable part of an estate when Egypt was famous for its wines in the days of the Greeks and Romans; and it is evident that wine must have been highly prized in earlier times from several kinds being enumerated in the inscriptions, and from its always being seen at the feasts. Besides the vine, other fruit-trees were cultivated, and especially the palm-tree. These will be afterwards mentioned in speaking of the productions of Egypt, which are now, for the most part, the same as in early times. The gardens were often extensive, and laid out with great formality (partly the result of their being watered in the same manner as the fields generally), and containing tanks for fish as well as for purposes of inundation.[5] The Egyptians paid great atten-

Egypt.

tion to preserving fish, and the product of the fisheries of one great artificial lake, that of Mœris, formed an important branch of the revenue. There were also tracts left to reeds, which, if not planted, were at least carefully maintained, on account of their value for manufactures, and as covers for wild-fowl.

The agricultural labourers, like the herdsmen, were regarded as a degraded class, and seem not to have possessed land of their own, except in very early times. Indeed, it is stated in the Bible that Joseph purchased the whole of the land of the Egyptians for Pharaoh, and gave the people seed to sow it, claiming a fifth of the produce as the king's right. The land of the priests alone was not purchased.[1] Diodorus Siculus relates that anciently the land was the property of the priests, of the king, and of the military class,[2] and the monuments leave little room to doubt that such was generally the case. The two accounts are reconciled by supposing that the military class soon regained their land.

Modern agriculture.

The agriculture of the modern Egyptians differs little from that of the ancient inhabitants. In one respect it is the converse of the old culture, for while the ancients excelled in the management of dikes and dams, and neglected the raising of water except by a simple and rude machine, or the still simpler method of carrying it in buckets, the moderns, while they have paid less attention to the great canals, and the means by which they were regulated, have employed far more ingenious means of artificial irrigation. The deficiency of population has partly caused the decay of many of the canals, and the neglect of many of the dams and dikes, and has at the same time necessitated the economizing of human labour, for which that of oxen has been substituted in a great measure.

Of the machines the most common is the shâdoof, already described, but there are also two kinds of water-wheels. The more usual of these is that called the sâkiyeh, which is composed of a horizontal wheel turned by oxen, and connected with a vertical wheel which is on the same axis as another around which are earthen pots in which the water is raised and poured into a trough. The tâboot is a similar machine, which differs from the sâkiyeh principally in having a hollow wheel instead of the wheel with pots, in the jaunts or fellies of which the water is conveyed. Sometimes a katweh is employed, which is a bucket like that of the shâdoof, having four cords by which two men dip it into the river or canal and raise the water.[3]

"The 'rei' lands (or those which are naturally inundated) are, with some exceptions, cultivated but once during the year. After the waters have retired, about the end of October or beginning of November, they are sown with wheat, barley, lentils, beans, lupins, chick-peas, &c. This is called the 'shitawee' (or winter) season. But the 'sharâkee' lands (or those which are too high to be subject to the natural inundation), and some parts of the rei, by artificial irrigation are made to produce three crops every year; though not *all* the sharâkee lands are thus cultivated. The lands artificially irrigated produce, first, their shitawee crops, being sown at the same period as the rei lands, generally with wheat or barley. Secondly, in what is called the 'seyfee,' or in the southern part of Egypt the 'keydee' or 'geydee' (that is, the summer) season, commencing about the vernal equinox, or a little later, they are sown with millet ('durah seyfee'), or with indigo or cotton, &c. Thirdly, in the 'demeereh' season, or period of the rise of the Nile, commencing about or soon after the summer solstice, they are sown with millet again, or with maize ('durah shâmee'), &c., and thus crowned with a third harvest. Sugar is cultivated throughout a large portion of Upper Egypt; and rice in the low lands near the Mediterranean."[4] The culture of cotton was introduced by Mohammad 'Alee with a view to promote his manufacturing schemes, and the Turkish grandees have found it a source of temporary profit. The necessity, however, of constructing dams to exclude the Nile water from the cotton-growing fields has rendered the inundations destructive, and the speculation seems on the whole to have injured the welfare of Egypt.

The agricultural implements of the modern Egyptians are rude in construction, and similar to those anciently employed in the country. One of these, however, was not known to the earlier inhabitants. This is the nórag, a machine "in the form of a chair, which moves upon small iron wheels or thin circular plates, generally eleven, fixed to three thick axle-trees, four to the foremost, the same number to the hindmost, and three to the intermediate axle-tree. This machine is drawn in a circle by a pair of cows or bulls over the corn." It is employed to separate the grain of wheat, barley, &c., and to cut the straw, which is used for fodder.[5] The ancient Egyptians, as before remarked, generally cut the wheat near the ear.

An Egyptian garden is in some respects a miniature of Egypt. It is intersected by numerous small channels which are filled by one or more water-wheels. By these channels the water is spread over the garden, divided by them into many square compartments, edged with ridges of earth. This system of course makes it very difficult to keep a garden in good order, and no great variety of flowers is cultivated.

Though Mohammad 'Alee Páshá was very desirous to encourage European manufactures, he did not sufficiently endeavour to apply modern science to the improvement of the native agriculture. Ibraheem Páshá, however, who succeeded him, always maintained that the country should be agricultural rather than manufacturing, and introduced important improvements during his father's government. In particular, he watered large tracts by means of powerful engines, and his estates were always noted for the excellence of their culture. But the shortness of his rule did not permit him to extend these plans, and they ill suited the oriental apathy of Abbás Páshá. Whether the present governor will adopt a wiser policy than his predecessor cannot yet be perceived, but his abolition of certain government monopolies augurs well for the future. The first popular acts of a new ruler do not, however, always indicate the course he will pursue.

Tenure of land.

Before the time of Mohammad 'Alee a kind of feudal system prevailed, and much of the land was possessed by small proprietors under the protection of the great emeers. By the massacre of the Memlooks, the páshá destroyed feudalism, and by arbitrarily seizing almost all the landed property, rendered private tenure of land a most rare condition. He allotted to those whom he thus unjustly dispossessed annual pensions for life, as the only compensation for an act of tyranny to which even the history of Egypt scarcely affords a parallel.[6] But this cruelty was carried still farther, and those whose lands were not confiscated, through fear yielded them up, so to speak, voluntarily, and buried their title-deeds, which are yet so concealed. A system of government which suffers the supreme authority to overlook such acts, and subordinate governors to perpetrate them, in defiance of the Muslim code and Arab jurisprudence, demands the most thorough and searching reform.

Lakes of Egypt.

Egypt has always been famous for its lakes, which have either aided commerce or supplied the inhabitants of the country with fish and wild fowl, or with some valuable production, or assisted in regulating the effects of the inundation. All have enriched the land in some one of these

Egypt.

ways, and thus they have been important sources of its natural wealth.

Lake Mareotis.

Commencing our examination at the north-western extremity of Egypt, we first observe the lake now called Boheyret-Maryoot,[1] and anciently Lake Mareotis. This is an extensive salt marsh rather than a lake, excepting during the inundation, when its contents are augmented by filtration. Its shape is that of an irregular right-angled triangle, whereof the hypotenuse extends from east to west for a space of about forty miles. At its eastern extremity the lake is of little breadth, and separated by only a narrow strip of land from the sea. It scarcely widens for about half its length, and then suddenly becomes very broad to the south of Alexandria. Not far beyond that city its shore changes in direction, and the distance from the sea for the first time becomes greater. The eastern side, which is the shortest, has a south-easterly direction, and the lake is here of considerable breadth. Anciently Lake Mareotis was navigable, and thus contributed to the commercial importance of Alexandria. The country around was cultivated, and produced the famous Mareotic wine. The relations of various travellers show that it was still a lake during the fifteenth and sixteenth, and as late as towards the close of the seventeenth century after the Christian era; and one of these writers, Villamont (in 1590), mentions that in his time the fisheries produced a considerable sum.[2] When, however, the French army conquered and occupied Egypt (1798–1801) they found its basin to be "a sandy plain, of which the lower portion retained the rain-water, which remained there for a great part of winter." It probably had dried up towards the close of the seventeenth century or beginning of the eighteenth.[3] On the 4th of April 1801 the English army, which was co-operating with that of the Grand Vezeer against the French garrison of Alexandria, cut the dikes of the canal of that city, and thus admitted the waters of the Lake of Aboo-Keer into the ancient bed of Lake Mareotis, in order to cut off the water supply of the besieged.[4] The basin of the lake being, however, partially inhabited, some loss of life and property was the result of this act, which has been much called in question, and not without reason. The unhealthiness of Alexandria is also traceable to the formation of this marsh. The precedent thus set has been twice imitated, first by the Turks in 1803, and a second time by the English army under General Fraser in 1807.[5] At the present day the lake or marsh is unprofitable, and its shores are uncultivated and uninhabited, the whole wearing the most dreary and melancholy aspect.

Lake of Aboo-Keer.

To the north of Lake Mareotis is situate that of Aboo-Keer, called by the modern Egyptians Boheyret-Aboo-Keer. It is simply the northernmost portion of the former lake, from which it is separated by the Mahmoodeeyeh Canal (which here occupies the site of the older Canal of Alexandria), and the embankments or dikes which form its banks. It is very small, nowhere measuring ten miles across; and extremely shallow, usually not exceeding three feet in depth. The water is salt, being chiefly derived from the sea, from which it is separated by a narrow strip of land on the western side, and on the eastern by a similar strip of far less breadth, the shore of the ever memorable Bay of Aboo-Keer.

Lake of Atkoo.

To the east of the lake of Aboo-Keer is that of Atkoo, or Boheyret-Atkoo. It spreads when full nearly to the town of Rosetta, and is separated from the sea by a narrow neck of land on which stands the large village of Atkoo. Its extent varies according to the quantity of water which it receives from the inundation.[6]

Lake of El-Burullus.

The great lake of El-Burullus commences a little to the eastward of the Rosetta branch of the Nile, and stretches to somewhat beyond where the canal which was anciently the Sebennytic branch enters it, and passing through it reaches the sea. Like the other northern lakes, it is separated from the Mediterranean by a narrow strip of land, and its shore on that side is similar in direction to the coast of Egypt. For two-thirds of its extent from its western end it takes a north-easterly direction, and then turns towards the south-east. Its southern shore is extremely irregular, and not far from it are most of the numerous islands which diversify its surface. The greatest extent of the lake, measured in a line from the eastern to the western extremity, exceeds forty miles, and it is throughout very shallow.[7] It is chiefly known for its water-melons, which are yellow within instead of being red or pink, and come into season after those grown on the banks of the Nile.

Lake of El-Menzeleh.

The easternmost of the lakes of Egypt is Boheyret-el-Menzeleh, which greatly exceeds the others in size. It extends from very near the Damietta branch of the Nile to the mouth of the old Tanitic branch, which is now called the canal of El-Mo'izz, and passes through this lake to the sea. It also receives the waters of the canals which were once the Mendesian and Pelusiac branches. The northern shore is separated from the sea by an extremely narrow strip of land, and slopes from the west in a south-easterly direction, and the southern shore is very irregular, although its distance from the northern generally does not vary much. At its south-eastern extremity is a long marshy creek extending into the desert. Its average length is about forty miles, and its average breadth about fifteen. Its depth is greater than that of the other lakes, and the water is salt, though mixed with fresh, and therefore not pure sea-water. Upon the surface are numerous islands, and the whole lake abounds in reeds of various kinds. It supports a considerable population of rude fishermen, who dwell in villages on the shore and islands, and live upon the fish of the lake. This fishery was a government monopoly, and probably is so still unless Sa'eed Páshá has abolished it with the other monopolies. The reeds are cover for water-fowl of various kinds which the traveller sees in great numbers, and wild boars are found in the marshes to the south.[8]

Lake Serbonis.

The Lake Serbonis, so well known in ancient times as having swallowed up those passing over its marshes concealed by shifting sands, is now dry, and little danger is to be feared by those who cross it. It cannot indeed be any longer included in the list of the lakes of Egypt.

Bitter Lakes.

Besides the lakes above mentioned are those called the Bitter Lakes, which should rather be termed marshes, occupying part of the ancient bed of the Red Sea between Suez and Lake Menzeleh, and the Natron Lakes. The latter are very small, and situate in a valley of the western desert, not very far from the river; this valley will be noticed in a future place.

Natron Lakes.

Lake of El-Karn.

In Upper Egypt there is but one lake of sufficient importance to claim a separate notice. It is the Birket-el-Karn or Lake of El-Karn, at the extremity of the Feiyoom, which is, as already mentioned, an oasis on the western side of the river, to which an opening in the mountains leads. It is about 35 miles long, and its widest part a little exceeds 7 miles, according to Sir Gardner Wilkinson, while in several places it is considerably narrower. About the middle is a single island. The depth is not great, and the same author,

[1] "Boheyreh" (pronounced "Boheyret" when followed by a genitive), signifies "a little sea," being the diminutive of "bahr" a "sea," and is applied to large lakes, smaller ones receiving the appellation "birkeh." The distinction is however not always maintained, and the great lake of the Feiyoom is called Birket-el-Karn, although from its size it should be called a boheyreh.

Egypt.

who "sounded in several places," "found what is considered the deepest part to be only $28\frac{1}{2}$ feet."[1] Its level is considerably below that of the Nile, as the bank of the river at Benee-Suweyf, which is at the entrance of the valley leading to the Feiyoom, is upwards of a hundred feet higher than the water of the lake.[2] The shores are barren or uncultivated; the northern is desert and bounded by sandy mountains; the southern was in ancient times partly cultivated. The water is brackish and unwholesome, though the fishermen, of whom there are a few, drink it habitually.

Lake Mœris.

The famous Lake Mœris lay between the Feiyoom and the Nile, and not far from the river. It was an artificial work executed by an ancient Pharaoh, whose name it bore, and may rather be described as having been a broad canal than a lake. The irrigation of neighbouring tracts was regulated by Lake Mœris, and its fisheries, as before mentioned, formed an important part of the revenue. Subsequently to the subjugation of Egypt by the Romans its dikes were neglected, and by degrees it became ruined. Until lately its position and extent were considered doubtful, but M. Linant's excellent memoir, published by the Egyptian Society of Cairo, has established these points most satisfactorily from the remains of its basin, which are yet traceable.

Canals of Egypt.

Mahmoodeeyeh Canal.

The canals of Egypt deserve especial attention from their great importance in extending the beneficial influence of the inundation. In Lower Egypt we find, beginning from the east, first the Mahmoodeeyeh Canal, which connects Alexandria with the Rosetta branch of the Nile, taking a similar direction to that of the ancient canal which it has succeeded. It was dug by the orders of Mohammad 'Alee, and although not quite 50 miles in length, and not 100 feet broad, about 12,000 labourers are said to have died in ten months while the work was in progress.[3] This is well known to be a tolerably accurate statement of the losses experienced by the unfortunate workmen, and is only one of the many instances which the history of our own times affords of that reckless disregard of human life, which is one of the worst traits of Turkish character, and strikingly distinguishes the cruel 'Osmánlee from the humane Arab.[4]

Canal of Manoof.

Between the Rosetta and Damietta branches of the Nile are several canals, some of which are of importance, particularly the short canal of Manoof connecting the two branches not far from the point of the Delta. To the east of the Damietta branch are others, whereof the most remarkable occupy the beds of the Tanitic and Pelusiac branches, which have been cleared to a sufficient extent to form canals. The former of these, which lies to the westward of the other, is called the Canal of El-Mo'izz, the first Fátimee khaleefeh who ruled in Egypt, having been dug by his orders, and the latter bears the name of the Canal of Abu-l-Munegga, a Jew who executed this work, under the Khaleefeh El-'Amir, in order to water the province called the Sharkeeyeh. The last-mentioned canal is connected with the remains of that which anciently joined the Nile and the Red Sea. Of this important work the greater part has been destroyed through neglect, but it might be restored without a very great expenditure. It was of the Pharaonic times—having been commenced according to ancient writers by Sesôstris[5] or by Neco II.; most probably by the former, since Rameses II., who is generally intended by the Sesôstris of the Greeks, has left a record of his reign in its vicinity.[6] It was continued by Darius Hystaspis, and at length finished by Ptolemy Philadelphus. The reopening of this canal, or the cutting of another from the Mediterranean to the Red Sea, has been proposed in our own times, but both projects have given way to that of a railway, which is now in course of construction. A ship canal joining the Mediterranean and the Red Sea is now (January 1855), however, contemplated, but it is generally believed that it will not be carried out.

Canal of El-Mo'izz.

Canal of Abu-l-Munegga.

Canal of the Red Sea.

Bahr-Yoosuf.

The extent and character of the great canal called the Bahr-Yoosuf or River of Joseph, which runs parallel with the Nile on its western side, from a little below Cairo to near Farshoot, a distance by the river of about 350 miles, render it the most important work of the kind in Egypt. It is a continuous series of canals rather than one canal. Although the Joseph whence it takes its name is the celebrated Saláh-ed-deen, the Saladin of our historians, yet it is related that he merely repaired it, and it is not doubted to be of a much earlier period. Most probably it was executed under the Pharaohs; and there would seem some reason in the Arab tradition that it was the work of the patriarch Joseph, were it not for the circumstance that such a story would naturally arise from its name. In the present day it is not navigable except during the season of the inundation, and at other times is dry in various places. To restore it would not be a work of extreme difficulty, and would greatly benefit the commerce and agriculture of the country, perhaps more than any other undertaking of the kind.

Botany.

Egypt differs from most other countries in having neither woods nor forests. Besides the palm groves, we rarely see even a grove of trees, except in Lower Egypt. The largest common trees are acacias, sycamore-fig-trees, and mulberry-trees, all of which are frequently planted on each side of the great roads near Cairo; and the most beautiful trees are the date-palm and the banana. The beauty of the palm is, however, in a great measure owing to art; for its lowest branches are annually cut, which causes it to grow high, and renders its head of elegant form. On this account the ancient Egyptians adopted a palm branch as the symbol of the year.[7] When wild, this tree has a far inferior appearance, being low, and having long ragged branches reaching to the ground; and its dates are small and poor in flavour. The Theban palm is a very different tree, having two great branches, each of which divides into two other branches, a subdivision which continues still farther. The weeping-willow, myrtle, elm, and cypress, are found in the gardens and plantations, with various trees bearing the fruits to be next mentioned; and the tamarisk is to be seen everywhere.

The more common of the fruits are dates of various kinds; which are sold half-ripe, ripe, dried, and pressed in their fresh moist state in mats or skins. Many different sorts are enumerated as known in Egypt. The dependencies,

[1] *Modern Egypt and Thebes*, vol. ii., pp. 344–5. [2] *Id.*, p. 346. [3] *Englishwoman in Egypt*, vol. i., pp. 47–8.

[4] Writers on the East have not generally been careful to distinguish the Turkish and Arab national character, and the former has thus had the advantage of the virtues of the latter, which has received in return the stigma of the other's vices. The remarkable characteristics of Arab character are high honour, generous hospitality, and humanity; coupled with much deceit in small matters not considered points of honour, carelessness as to religion, though not irreligion, and a love of plunder. The Turkish character is as strongly marked by treachery, often of the blackest kind; little hospitality, particularly to strangers; cruelty and disregard of human life; bigotry as to their religion, which is now giving way to deism; and the same love of plunder which is so common among the Arabs, as well as darker vices unknown to them, which have rendered the Turkish name a bye-word in the East, as well as in the West. The conquests of the Arabs were not marked by desolation; their rule has preserved and even improved the philosophy of Greece, which was welcome at the court of Baghdád when unknown in Europe: architecture among them attained an excellence scarcely rivalled elsewhere in modern times. The rule of the Turks is traced by ruined cities, and whole provinces laid waste; literature has forsaken its most famous seats, Constantinople, Athens, Alexandria, and Antioch; the arts have decayed. Until they held Egypt and Mesopotamia, these were the richest countries of the world, now they are half deserts. All these are facts which can be proved.

Egypt.

however, and not Egypt, produce the finest of these dates. The hotter and drier climates of the Oases and Lower Nubia best suit the date-palm; and the pressed dates of Seewah, the ancient Oasis of Jupiter Ammon, are among the most esteemed. The dates of Mount Sinai are generally poor, but the good monks of the convent of St Catherine make of them an excellent conserve, taking out the stones and placing almonds in their stead, and then pressing them together and packing them in gazelle-skins. The grape is a common fruit, but wine is not made from it on account of the prohibition of Mohammed. The Feiyoom is celebrated for its grapes, and chiefly supplies the market of Cairo. The most common kind of grape is the white, of which there is a small kind far superior to the ordinary sort. The black grapes are large, but comparatively tasteless. The vines are trailed on trelliswork, and form agreeable avenues in the gardens of Cairo; but little attention is paid to their culture, the common fault of Egyptian agriculture and gardening, resulting from the generosity of nature and the indolence of the inhabitants.

The best known fruits, besides dates and grapes, are figs, sycamore-figs, and pomegranates, apricots and peaches, oranges and citrons, lemons and limes, bananas, which are believed to be of the fruits of Paradise (being always in season), different kinds of melons (including some of aromatic flavour, and the refreshing water-melon), mulberries, and Indian figs, or prickly pears, the fruit of the lote-tree, and olives. Many of these are excellent, especially the figs and melons. The trees and plants which produce most of them are chiefly confined to the gardens. The cactus bearing the Indian fig is extremely common, and forms the hedges of gardens and plantations.

The general plan of an Egyptian garden has been already described. Although seldom in good order, such a garden is often picturesque; having a few date-palms and bananas, and perhaps overlooked by a house of the old style of architecture. No great variety of flowers is cultivated. Among the more usual are the rose (which has ever been a favourite among the Arabs), the jasmine, narcissus, lily, oleander, chrysanthemum, convolvulus, geranium, dahlia, basil, the hinnè plant (or Egyptian privet, which is said to be a flower of Paradise), the helianthus, and the violet.

The vegetables, &c. are very common and of various kinds, so that we cannot wonder that the Children of Israel longed for them in the desert. The principal are beans, peas, vetches, lentils (whereof a pottage is made, which is the common food of the Nile boatmen), lupins, chick-peas, the lubia (*Dolichos lubia*), fenugreek, mallows, the bamiyeh (*Hibiscus esculentus*), spinach, purslain, melookheeyeh (*Corchorus olitorius*), leeks, onions, garlic, celery, parsley, chicory, cress, radishes, carrots, turnips, colocasium, lettuce, cabbage, fennel, gourds and cucumbers (both of several kinds), the tomata, the egg-fruit or badingân (black and white), caraway, coriander, cumin, aniseed, and red pepper.

The chief field-produce is wheat (which is more grown than any other kind of corn), barley, several sorts of millet, maize, rice, oats, clover, peas, the sugar-cane, roses, two species of the tobacco-plant, and cotton. The sugar-cane is extensively cultivated, and excellent sugar is manufactured from it. There are fields of roses in the Feiyoom, which supply the market with rose-water. The tobacco produced in Egypt is coarse and strong compared with that which is used by the middle and upper classes, and imported from Syria and Turkey. That of Syria is considered the best. Of textile plants, the principal are hemp, cotton, and flax; and of plants used for dyeing, bastard saffron, madder, woad, and the indigo plant. The intoxicating hasheesh—which some smoke in a kind of water-pipe formed of a cocoa-nut, two tubes, and a bowl, seldom used for any other narcotic—is not, as has been erroneously supposed, opium, but hemp. The effect is most baneful. The leaves of the hinnè plant, already mentioned, are used to tinge of a bright red colour the palms of the hands, the soles of the feet, and the nails of both hands and feet, of women and children, the hair of old ladies, and the tails of horses. Indigo is very extensively employed to dye the shirts of the natives of the poorer classes, and is, when very dark, the colour of mourning; therefore, women at funerals, and generally after a death, smear themselves with it. Oil is extracted from the seeds of the cotton plant, hemp, colewort, the poppy, the castor-oil plant, sesame, and flax. The high coarse grass called halfeh (*Poa cynosuroïdes*) grows in great quantity in waste places and among ancient ruins.

Many kinds of reeds are found in Egypt, though, if we compare the representations in the tombs of the ancient Egyptians with what we see in the present day, it is evident that they were anciently much more common. That they should be wasted away, was prophesied by Isaiah (xix. 6, 7). The famous byblus or papyrus, from which paper was manufactured in old times, appears to be nearly, if not quite extinct, since Sir Gardner Wilkinson has never seen it.[1] M. Delile, in his excellent account of the Egyptian flora, merely mentions it by name in his list as the *Cyperus papyrus*, called in Arabic *berdy*, and found at Damietta,[2] but gives no figure of it. The lotus, so prized for its flowers by the ancient inhabitants, is still found in Egypt, though it is not common. The French naturalist above mentioned enumerates three species which formerly grew in that country—one with white flowers, another with blue, and a third with rose-coloured, the last of which is now extinct there.

Zoology.

The zoology of Egypt is not of remarkable interest, although it contains some very curious points. The absence of jungle and of forests, and the little shelter thus afforded to beasts of prey, as well as other wild animals, partly causes this; and we observe few birds of beautiful plumage for the same reason. Such an open country is rather fitted for birds which will not be so easily remarked as would be the brilliant ones of the forests of India and Brazil.

One of the most characteristic of the beasts is the camel, which is more at home in the dry climate of Egypt than elsewhere out of its native deserts. It has been remarked, however, that the camel, like his master the Arab, degenerates when removed into a city or a cultivated tract—that the former commonly becomes mangy, and the latter experiences a physical and moral degradation. The Egyptian camel is of the one-humped kind, which has been erroneously called the dromedary, whereas the dromedary is merely a swift camel standing in the same relation to the ordinary camel that our saddle-horse does to our cart-horse. Camel's flesh is for the most part eaten only by the peasants and the Arabs of the desert; by the Copts it is considered unlawful food.

It is very remarkable that no representation of the camel has been found in the sculptures and paintings of the Egyptian monuments, among the very numerous figures of the animals of Egypt both tame and wild, and of those brought from foreign lands as presents. It does not appear to have been introduced into other African countries, until after the Christian era;[3] but it must have been known to the Egyptians, although it is by no means certain that it was one of their domestic beasts. Two passages in the Bible which speak of camels in the possession of Pharaohs,[4] refer to the time at which the foreign tribes called Shepherds were in Egypt; and it is almost certain that those

[1] *Modern-Egypt and Thebes*, vol. i., p. 441.

[2] "*Cyperus papyrus*, Linn.—Arab. *berdy*, Damiatæ." *Description de l'Egypte*, tom. xix., p. 71. Other Cyperi are described at pp. 125–6, and 130–2 of the same volume.

[3] Comp. Desmoulins, Mem. lu à l'Institut, 28 Juin 1823.

[4] Gen. xii. 16; Ex. ix. 3.

very Pharaohs were of the Shepherd races. Perhaps the camel was peculiarly the animal of one or all of those races, and therefore omitted in the representations of the monuments as an ill-omened and hateful beast.

To modern Egypt the camel is very valuable, since the traffic with Syria, Arabia, Western Africa, and Ethiopia, is mainly carried on by caravans. But the ancient Egyptians appear to have derived their wealth more from tributary presents than from commerce, to have allowed their land commerce to be much in the hands of foreign merchants, like those who brought Joseph into Egypt, and to have left even their sea commerce partly at least in foreign hands.

In old times the horses of Egypt were famous, and the armies of the Pharaohs were noted for their war chariots. From Egypt Solomon, and in his time all the kings of the Hittites and the kings of Syria, had horses and chariots.[1] And long after, when first the kingdom of Israel and then that of Judah endeavoured to throw off the yoke of the great kings of the East and made alliance with Egypt, they put their trust in Pharaoh's horses.[2] In the representations of battles fought by the kings of the Eighteenth and Nineteenth Dynasties we see no Egyptian cavalry, but only chariots, called *cavalry* in the inscriptions. At later times they may have had cavalry, properly speaking, of their own, and perhaps at all times among the mercenary or auxiliary forces.

In the present day the horses of Egypt are of a very indifferent breed, and the best that one sees in that country have been brought from Arabia and Syria, but these are seldom of great excellence. It is indeed surprising to find so few really good horses in a country bordering on Arabia; and not many years ago this was still more remarkable, though not during the existence of the Memlooks. The finest Arabs, however, are kept in the background by their possessors, partly for fear of the "evil eye," and partly, in the case of all but the highest personages, to avoid their forcible seizure by those of greater rank and power.

The Egyptian ass holds a middle place between that of Great Britain and the wild ass, which is more swift of foot than the horse. It is tall and handsome, docile, and having excellent paces, particularly a quick and easy amble. Thus it is well suited to the narrow streets of the metropolis, and of the other towns of Egypt, and is therefore commonly used for riding by persons of the middle and lower classes. Although asses are generally much cheaper than horses, the price of a fine ass exceeds that of an ordinary saddle-horse. The mules are handsome, but noted for vice, and what is very remarkable, for not being sure-footed.

The neat cattle are short-horned, rather small, and, as of old, very beautiful, speaking artistically. They are exceedingly quiet in disposition, and much valued for agricultural labour by the people, who therefore very rarely slaughter them for meat, and then only for the Franks. Buffaloes of an uncouth appearance and of a dark slaty colour, strikingly contrasting with the neat cattle, abound in Egypt. When voyaging on the Nile, one often sees them standing or lying in the river by herds. They are perfectly mild, and the little children of the villagers often ride them to or from the river. They are sometimes slaughtered, but their flesh is tough and coarse. Sheep (of which the greater number are "black") and goats are abundant in Egypt, and the flesh of the former is the ordinary butcher's meat. Swine are very rarely kept, and then almost wholly for the Franks; the Copts generally abstain from eating their meat. It appears that the ancient Egyptians, though they were not forbidden this flesh, in like manner rarely eat it, perhaps because it is so extremely unwholesome in a hot climate.

The Muslims consider dogs unclean, and therefore those of Cairo and most of the towns are half-wild and without masters, living upon offal, and upon food thrown to them by charitable persons. In the villages, however, and particularly in the Thebaïs, their case is better, for they are kept as guards to protect live-stock from thieves, and from hyenas and other wild animals, which come down from the mountains and deserts by night in quest of prey. The common dog of Egypt is generally of a sandy colour and strong, though not remarkable for courage; but in Upper Egypt, about Thebes, there is a fierce breed of dogs with wiry hair, generally black, and much esteemed for courage by their masters. Cats are as numerous in Cairo as dogs, and many of them are as homeless. They are, however, regarded with favour by the natives, who assign as their reason that the prophet Mohammad was fond of cats. This may perhaps be regarded as a relic of the veneration in which they were held by the ancient Egyptians. By them the cat was considered one of the sacred animals, and more highly reverenced than was perhaps any other. It was the emblem of the goddess Pasht, whom the Greeks called Bubastis. Diodorus Siculus relates an anecdote which shows to what an extent the veneration for this animal was carried. He tell us, that when he was in Egypt he was an eye-witness of the popular vengeance on a Roman who had accidentally killed a cat. Although the people were most anxious to conciliate the Romans, and were in great fear of them, neither this fear nor the interference of the king, prevented the unintentional culprit losing his life through their rage.[3] It is not a little curious, that there is at Cairo a royal foundation for the support of destitute cats. The author of this charity was the famous Memlook Sultán, Edh-Dháhir Beybars, whose humane intentions have of late years been sadly neglected by the trustees.

The wolf, fox, jackal, and hyena, chiefly inhabit the deserts and waste places of Egypt, and lurk in the ancient tombs and deserted quarries. The wild cat is also found in that country, though it is not common. The weasel abounds in Cairo, and is proverbial for its mischievous and revengeful disposition, and rats and mice are not among the least of the plagues. The ichneumon, jerboa, hare, and hyrax, are likewise natives of Egypt or its deserts, and the tame rabbit is kept for food.

The beasts of the chase which inhabit the deserts on either side of the Nile are antelopes of various kinds, and the wild ass esteemed by the Arabs and Persians to be the prince of game. It is found in the southern part of the Eastern Desert. The most beautiful of the antelopes is the gazelle, which is often tamed and kept in the large courts of the houses of Cairo. In Lower Egypt, principally in the desolate marshes near the Mediterranean, the wild boar is found and occasionally hunted. It is however a timid and rare animal, so that the sport is not, like the boar-hunting of other countries, exciting and dangerous.

From the representations in the tombs of the ancient Egyptians we see that in old times the hippopotamus was one of the wild beasts of the country. It has now retreated above the First Cataract, the southern boundary of Egypt, and is rarely observed below the Second Cataract. The crocodile has retreated in the same manner, and instead of being found throughout the Nile in Egypt, is rarely seen by one who is ascending the river, until he is many miles south of Cairo. The name of the island of Elephantine, situate a little to the north of the First Cataract, bearing the same signification in hieroglyphics as in Greek, makes it probable that at some remote period elephants were found in Upper Egypt, though now they are not seen north of Abyssinia.

In exploring the tombs and dark parts of the temples the traveller is annoyed by crowds of bats, which extinguish his candle, fly into his face, and cling to his clothes, some-

[2] Isaiah xxxi. 1.

[3] Lib. i., cap. 83.

Egypt.

times rendering examination impossible without a lantern. One species is very large, but the common one is small.

Birds of prey are numerous in Egypt, and of many kinds. Of the most remarkable are three species of large naked-necked vultures, the Arabian (*Vultur monachus*), the sociable (*Otogyps auricularis*, G. R. Gray—*Vultur nubicus*, Ham. Smith), and the fulvous (*Gyps vulgaris*, Sav.); as well as the smaller species called the aquiline vulture (*Nephron percnopterus*). The aquiline vulture has a feathered neck, and when standing is by no means a handsome bird, but it is much to be admired when on the wing from the contrast of the black and white of its plumage, and the steady manner in which it soars in circles. Perhaps the bearded vulture breeds in the most lofty parts of the desolate mountains of the desert between the Nile and the Red Sea; for when the French army was in Egypt, one of these birds was killed. It was of extraordinary size, for M. Larrey states that it measured more than fourteen Parisian feet, that is, more than fifteen English, from point to point of its expanded wings. Several species of eagles and falcons, two kinds of hawks, the common buzzard, and the moor-harrier, live in Egypt, or visit that country, according as they are migratory, erratic, or sedentary.

The common kite abounds at Cairo, and is one of the chief scavengers of the city; the others being the crow, the aquiline vulture, the half-wild dog, and the cat. The ruins and tombs of Egypt, and the modern houses, scarcely ever in perfect repair, shelter owls of various kinds.

The Spanish sparrow, which differs little from that of Britain, the water-wagtail, linnets, and larks, are among the birds of Egypt. The kind of kingfisher which is commonly seen on the Nile, perched on some eminence, and darting suddenly to seize a fish, is very inferior in its plumage, which is speckled, black and white, to the common kingfisher, which is also occasionally seen. The beautiful hoopoe is among the least rare birds, and there are also three species of bee-eaters. The hoopoe may be often seen in Cairo, where it is not only unmolested, but regarded with a sort of reverence, as the bird of Solomon; for the Muslims believe that there existed friendship between it and the wise king of Israel. Crows of the kind which we call the Royston crow are very numerous at Cairo. Birds of the swallow tribe, the woodpecker and the cuckoo, are also known in Egypt.

In the metropolis, in the towns and villages, and in the fields, no bird is more common than the pigeon, tame or wild. Pigeon-fancying is a favourite amusement of all classes at Cairo, and in the villages the pigeon-houses are often loftier than the huts upon which they are raised. Wild turtle-doves build in the courts of the houses of the capital. These courts often serve for the purpose of poultry-yards, in which fowls wander about without any care being taken of them, except that food is occasionally thrown to them. They are consequently meagre, and produce very small eggs. Turkeys, ducks, and geese are kept in the same manner.

Quails migrate to Egypt in great numbers, and sand-grouse, called by the natives kata, from their cry, are common in the deserts. There also the Arabs, like the ancient Egyptians, hunt the ostrich. A kind of red-legged partridge is likewise found in Egypt.

The islands of the Nile, the sand-banks which appear when the river is low, some of the lakes and marshes, the sheets of water caused by the inundation, and the mountains near the river, are the favourite resorts of many kinds of wading and of web-footed birds.

Of the waders the most interesting would be the sacred ibis of the ancient Egyptians, if that bird be really found in Egypt at the present day. But it does not appear certain that but one species was anciently held sacred; nor, if we admit that but one was revered, does it seem clear that this is the *Ibis religiosa* of Cuvier which is now known in Egypt.

The Egyptian plover is famous on account of the story, which modern observation has confirmed, related by Herodotus respecting it and the crocodile.

Among the most common waders are the spur-winged plover, the snow-white egret, which has been erroneously called the ibis, and the pelican. The cormorant, too, is often seen, as are wild geese and ducks, both of several kinds.

Of the many reptiles the crocodile deservedly occupies the first place. It is seldom observed in the present day far north of Asyoot, the capital of Upper Egypt. Several crocodiles are generally seen basking in the sun in the heat of the day on a sand-bank: at the approach of a boat they quickly plunge into the stream. They rarely attack a human being, but it is unwise to bathe in the river at places where they are reputed to be fierce, and to bathe at any distance from a boat in the part of Upper Egypt where they are found. It is said that the crocodile's common mode of attacking a person on shore who is near the river's edge, is to approach stealthily and sweep him into the stream by a blow of his tail, the great weapon of all the lizard-tribe. The smaller saurians are found in great numbers: of these a species of chameleon may be particularized.

Serpents and snakes are among the most common reptiles, and of various kinds, including the deadly cerastes and cobra di capello. The house snakes, however, which are so numerous at Cairo, are perfectly harmless.

Fishes abound in the Nile and in the Lake Menzeleh. The modern inhabitants of the country are partial to fish as food, but they say that only those fishes which have scales are wholesome. The fishes of the Nile are generally insipid in comparison to those of the sea; though a few of them, particularly the bultee (*Labrus niloticus*, Linn.), the kishr (*Perca nilotica*), and the binnee (*Cyprinus bynni*, Arted.), are of a delicate flavour.

One of the commonest insects is the dangerous scorpion. Its sting is very painful, and if no remedy is applied, sometimes fatal, particularly if a person is stung in the heel.[1] Large spiders are abundant, including more than one species of *solpuga*, incorrectly called tarantulas by the Europeans, and believed by the natives to be very venomous, but this is most likely an error. Egypt has ever been famous for what may be termed insect-plagues, but not to the extent that has been asserted by some modern travellers. Caution will enable one partially to escape the attacks of fleas and bugs, and altogether to avoid the more dreaded insect which is usually spoken of with them. Beetles of various kinds are found, including that which was anciently held sacred—the scarabæus. Locusts are seldom seen at all, and very rarely in large numbers. When, however, such is the case, they commit great havoc in the fields and gardens, reminding the beholder of the description of the plague of locusts which preceded the Exodus. Sometimes they merely cross the valley of Upper Egypt, and leave the mark of their passage in desolated fields, entirely stripped of verdure; and at other times they spread themselves for days, or even weeks, over the cultivated lands, committing far more extensive mischief. On an occasion of this sort, the government offered rewards for locusts killed and brought to the officials by the villagers.

Bees are kept in Egypt, and their honey is much prized by the inhabitants, who usually eat it in the clarified state. It is inferior to that of England, and also to the famous Greek honey. Butterflies and moths of many kinds are observed in the fields. There are plantations of mulberry-trees in the eastern part of Lower Egypt, for the rearing of silk-

[1] A little ipecacuanha, made into a paste with water and applied externally to the place stung, has produced, in the many instances in which the writer has seen it used, almost instant relief.

Egypt.

worms. The manufacture of silks was a government monopoly, but has probably lately ceased to be so. The silks of Egypt are generally inferior to those of Syria and other eastern countries, though some have been produced of great excellence. Among the other insects may be mentioned the common fly, rightly deserving a place among the plagues of Egypt, as does also the mosquito, which, however, is not found throughout the country.

Ancient inhabitants.

In the following remarks on the ancient Egyptians great assistance has been derived from the valuable work of Sir Gardner Wilkinson on their manners and customs, which has made us better acquainted with them than we are with any other people of antiquity. From the representations of their monuments, and from the mummies which have been unrolled, we are enabled to form an accurate idea of the personal characteristics of the ancient Egyptians. In consequence of a misconception of a passage in Herodotus (ii. 104), and confused notions respecting the inhabitants of Africa, it has been often supposed that the Egyptians were very nearly allied to the negro race. A careful examination of the most distinct data in our possession has, however, produced a far different result; and it is now acknowledged that they were more related to the Caucasian than to the negro type. It has also been shown that most of the modern inhabitants have preserved many of the characteristics of their ancient predecessors, and that it is, therefore, erroneous to suppose that the former are chiefly of Arab origin, although the intermixture of Arab as well as other blood has so much changed the national type, that it would not be safe to describe the earlier people from the appearance of the present. Nevertheless, one is often struck, among the remains of ancient monuments, by the similarity of an early representation to some one of the natives standing by, priding himself upon an Arab origin, and repudiating the stigma that he is of the race of Pharaoh.[1]

Personal characteristics.

Judging, then, from the monuments and mummies, the countenance of the ancient Egyptians was oval, and narrower in the case of the men than of the women. The forehead was small and somewhat retiring, but well-shaped; the eyes large, long, and generally black; the nose rather long, and with a slight bridge; the mouth expressive, with rather full lips, and white and regular teeth; the chin small and round, and the cheek-bones a little prominent. The hair was long, full, crisp, and somewhat harsh, and almost always of a black colour. The men had black beards, but they wore them in so artificial a mode that one cannot judge whether they were full or not. The skin of the men was of a dark brown, that of the women varied from olive to pink flesh-colour in different persons. The colour of the women was natural, and the darker hue of the men the result of exposure to the sun, and the scantiness of their clothing explains why their faces were not darker than the rest of their bodies.

Dress.

The dress of the ancient Egyptians did not much vary at different periods. At the time of the building of the Great Pyramid it was, however, simpler than under the rule of the Eighteenth and Nineteenth Dynasties, about a thousand years later. As the period last mentioned is that of which most sculptured and painted monuments remain, it will be best to describe what was then the dress of the inhabitants, and this description will apply, in its main particulars, to the preceding and subsequent times of their ancient history.

The men of all classes either had shaven heads, with skull-caps, or wore their own hair, or wigs, very full, and in numerous plaits or curls, falling to the shoulders, but sometimes much shorter and in the form of a bag; there is, indeed, reason to suppose that the practice of shaving the head was universal, except among the soldiers.[2] All the hair of the face was also shaven, except in the cases of kings and great persons, who had a small formal beard beneath the chin.

The king was distinguished from his subjects by the richness of his apparel. His head-dress was sometimes his own hair, or the wig, alone, in various forms, but not much differing in length; and at others he wore the high crowns of Upper and Lower Egypt—the former being a kind of conical helmet, and the latter, a short cap with a tall point behind, worn outside the other. He is also occasionally represented with another form of high cap.[3] The king often had the figure of an asp, the emblem of royalty, tied just above his forehead. His beard was about three inches long, and one inch broad and deep, and formally plaited.

The simplest royal dress was a kilt, usually reaching nearly to the knees, rather full in front, having a girdle above, from which hung before a broad band, richly ornamented, and peculiar to the king, like the lion's tail (natural or artificial) which was attached to it behind, and reached nearly to the ground. Sometimes a large and full shirt was worn over the kilt, descending almost to the ankles, and having wide sleeves reaching to the elbow: this outer dress is occasionally simply a skirt. Both these dresses were usually of white linen, and the upper dress was apparently very fine and transparent. Sandals were worn on the feet, and the ornaments were armlets, bracelets, both flat and broad, and deep necklaces, besides those above mentioned.[4]

The ordinary costume of men of the upper and middle classes was the same as that of the king—the short kilt, with sometimes the long shirt or skirt of fine linen above it, tied in various forms. Their beards were very short, scarcely exceeding an inch in length, and of a formal square shape, and they wore the full hair or wig, or a skull-cap.[5] They generally went barefooted, but sometimes used sandals. The priest was occasionally clad in a leopard's skin, either tied or thrown over the shoulder, or worn as a shirt, the fore-legs forming sleeves.[6] Military personages are often represented with helmets, and sometimes with short coats or corslets of plate-mail.[7] The royal princes were distinguished by a side-lock of curiously-plaited hair.[8]

The men of the lower class wore the kilt and girdle alone,[9] or, especially when engaged in laborious work, went altogether naked. They shaved the head and face, and had no head-covering but the skull-cap. The soldiers had kilts of different kinds, coats or corslets of plate-mail, and either wore full hair or helmets.[10]

The dress of the queen differed from that of other ladies alone in certain royal ornaments. It consisted of a tight skirt, supported by shoulder-straps, and bound at the waist by a girdle or sash, with long ends falling in front, and descended to the ankles. Over this was usually worn a full shirt of fine linen, with wide sleeves reaching below the elbows, and having a broad skirt falling to the ground. It much resembles the upper dress of the king, or of men of the better classes. The queen was distinguished by her head-dress, which was in the form of a vulture with outspread wings, the bird's head projecting over the forehead, and the wings falling on either side, while the tail extended behind.[11] Sometimes the queen is also known by the uræus or royal asp above her forehead, and at other times she is represented with various forms of head-dress.

Egypt.

[1] "Gins Fara'oon," or "Race of Pharaoh," is a common form of reproach addressed by the Turks to the Egyptians; the latter retort by calling their oppressors "Gins Nemrood," or "Race of Nimrod." "Pharaoh" and "Nimrod," as described in the Kur-án, may be regarded as impersonations of both tyranny and ungodliness, and they are therefore objects of especial hatred to all good Muslims.

Egypt. The queen also wore sandals. The princesses were dressed in the same manner. The dress of the ladies of the upper and middle classes was exactly the same as that of the queen, except that they more frequently appeared in the under garment or skirt alone.[1] The women of the lower class wore that garment only,[2] and sometimes it was much shorter than that of the ladies, particularly when they were engaged in manual labour.[3] The public female musicians and dancers usually were clad in the upper garment alone, and it appears to have been of the finest and most transparent stuff.[4] Occasionally the dancers had no dress whatever. The women's hair was worn in the same manner as the men's, but it was, of course, of greater length, usually reaching about halfway from the shoulders to the waist, being rarely longer, and sometimes much shorter. It was ornamented in various ways, but the general form was always the same.[5]

The dress of the children of all classes, when they were dressed at all, was very plain, though those of rich persons were sometimes attired as their elders. Boys were distinguished by the side-lock, which the princes also wore in a peculiar fashion, as before mentioned.

Religion. The religion of the ancient Egyptians cannot be said to be as yet fully unravelled. Notwithstanding the very numerous materials that we possess, the subject is so difficult that no one has advanced any distinct system of explanation applicable to the whole. In the following observations it is intended to arrange the principal tenets of this religion in as logical an order as may be, to enable the reader to judge for himself in the many points of difficulty which the matter presents.

The authorities for this part of the inquiry are the monuments and papyri of ancient Egypt: reference may be advantageously made to Greek and Roman works, such as Herodotus, Plutarch *De Iside et Osiride*, or whoever wrote that treatise, Macrobius, Iamblichus, and others; yet is it unsafe to base anything wholly on the statements found in these works, and with the ample materials which the monuments present, wholly unnecessary. Great care should also be taken not to acquire an incorrect view of this religion from the accounts of some of the late writers who interpreted it according to a philosophic system, whereof the monuments and papyri afford no distinct evidence. Many modern writers have accepted such interpretations, even since the Egyptian records have been accessible to them, and thus rendered the mythology more difficult of comprehension. The peculiar circumstances of these ancient interpreters should be borne in mind. They lived at a time when Greek philosophy had established among the learned a kind of deism in place of various forms of idolatry, and was endeavouring by it to oppose the spread of Christianity. That philosophy had rendered much of the ancient Egyptian religion ridiculous unless understood mystically, and it became the endeavour of the learned to systematize and explain so as to make the main doctrines of this faith consistent with one another, and the seeming absurdities, allegorical representations of physical and moral truths. Hence have arisen the errors of supposing the Egyptian religion to be, properly speaking, a system, and of concluding that everything contained in it must have some important signification, which errors have retarded the true explanation in a very high degree. If it can be shown that this religion is the offspring of various faiths, and that they have never been moulded together, on the one hand, and if it be admitted that other religions, such as those of ancient Greece and Rome, contained much that was puerile and unreasonable, on the other hand, then it must follow that the religion of ancient Egypt cannot properly be called a system, and that its tenets are not necessarily capable of a philosophical explanation.

Divinities. Manetho,[6] and Herodotus,[7] with other writers of less importance,[8] agree with the historical Turin Papyrus[9] in stating or implying that the reign of the gods, and then, according to the historian first mentioned, that of the demigods or heroes, and lastly, that of the manes, preceded the rule of mortals in Egypt. The consideration of the historical bearing of this statement belongs to a subsequent portion of the present article;[10] but it must be here mentioned, as, had we a complete list of the mythic rulers, we should probably possess one Egyptian classification of the divinities. The only reliable records are, however, in so mutilated a condition that it is unsafe to build any hypothesis upon them.

Herodotus states that the Egyptians had three orders of gods, the first, second, and third, whereof the first was the most ancient.[11] From what is said respecting them it is evident that these orders were mythic dynasties, while it appears almost as certain that the gods were arranged according to the importance of the towns in which they were worshipped,[12] and not according to the importance of the offices ascribed to them. This should be borne in mind when examining the relation of these dynasties to history. The orders of the gods therefore have nothing to do with the principles of the religion.

In order to form an opinion respecting those principles, it is desirable first to enumerate the chief divinities and their offices; then the ceremonies of their worship; and, lastly, the main doctrines with reference to man. From these data some leading ideas respecting the sources of the religion may be derived.

Num. Num, or Nu, called Kneph by the Greek writers, was one of the most important of the gods: he was worshipped throughout Ethiopia, in the island of Elephantine, and in the southern part of the Thebaïs.[13] He is represented as a man having the head of a ram and curved horns, with above the head broad horns more or less twisted.[14] The signification of his name, as stated by ancient writers, and verified by the most reasonable etymology, is "soul,"[15] and to him was ascribed the creation of both men and divinities, and of the material universe.[16] He seems thus to have corresponded to the soul of the universe of the philosophers, whereof so remarkable an account is given by Virgil in the Æneid.[17]

Egypt.

Seti.

Anka.

Kneph must not be confounded with Amen, who is sometimes, as in the Oasis called after him, represented under the form usually assigned to Kneph.[1] His consort is generally either the goddess Seti or Anka, the former of whom is represented as a female with the crown of Upper Egypt with high horns, or the crowns of Upper and Lower Egypt united,[2] and the latter likewise as a female, with a high head-dress, as if of feathers.[3] Sometimes, according to Sir Gardner Wilkinson, these form a triad.—The question of triads in the Egyptian religion is one of great difficulty. It cannot be denied, however, that triads were more frequently worshipped than one divinity or two divinities, and that the personages composing these triads were held to be related to one another.[4]

Amen.

The chief god of Thebes, Amen, bears more than one name, and is variously represented. His proper name, Amen, signifies the "hidden" or "concealed," as both the hieroglyphic inscriptions and ancient writers show, being derived from the verb *amen*, to "enwrap" or "conceal."[5] He is also called Amen-ra, the name of the sun-god, Ra, being added to his own; and in the inscriptions of the Roman times, Hammon-Cenubis, that is Amen-Num (Kneph). His peculiar form is that of a man wearing a cap with two very high and narrow plumes, and he is painted of a blue colour. But he is also represented with the figure of Khem the generative principle, when he is generally called Amen-ra ka mut-f, that is "the husband of his mother," according to the usual interpretation, which, however, may be considered doubtful.[6] Amen is further pourtrayed under the form of Kneph, the ram-headed god; and though when thus represented on the monuments he bears the name Amen-ra, he must also have received the name Amen-Num or Hammon-Cenubis before-mentioned. Amen was worshipped in the Great Oasis and in that called after him under the form last-mentioned, and hence arose the mistake of the Greeks and Romans who always assigned to him that figure.[7]

Mut.

The goddess Mut, or "the mother," is the companion of Amen, and seems to be the female form of Khem, or of Amen in the character of Khem. She is usually represented as a female wearing the crowns of Upper and Lower Egypt, and the vulture-head-dress of a queen.[8] There was also a feminine Amen, Ament ("*t*" being the feminine article), whose figure is that of a female with the crown of Lower Egypt.[9]

Khuns.

Khuns formed with his parents Amen and Mut the triad of Thebes. He is usually represented as a mummy-shaped male figure, differing from Ptah in having the crescent and globe of the moon upon his head, and in wearing the side-lock of a child. He is sometimes pourtrayed as a hawk-headed figure, likewise with the moon on his head; in this form he is connected with Ptah-Sokari-Osiris, and Ra the sun-god.[10]

Khem.

Khem was a god by whom the productiveness of nature was emblematized. He was represented as a swathed Phallic figure with a single arm, above which was a flail, raised behind his head, and wearing the high-plumed cap of Amen.[11] The reading of his name is still doubtful; the most probable one, Khem, reminds one of the patriarch Ham from whom the Mizraites were descended. The Greeks identified him with Pan, and called Chemmis, a city in the Thebaïs where he was worshipped, Panopolis. The monuments afford no evidence that obscene rites were celebrated to him; indeed nothing is more remarkable than the coarseness of allegorical representations of Khem and other divinities, which

Igneus est ollis vigor et cœlestis origo
Seminibus, quantum non noxia corpora tardant,
Terrenique hebetant artus, moribundaque membra.
Hinc metuunt, cupiuntque: dolent, gaudentque: neque auras
Dispiciunt clausæ tenebris et carcere cæco.—*Æn.*, lib. vi., v. 724–734.

Know first, the heavens and earth, and liquid plains,
And the moon's shining orb, and sun-like stars,
A spirit nourishes within, and mind
Prevading every part, governs the whole,
With the vast fabric mixing: hence the race
Of men and beasts, and all the flying tribes,
And the great monsters which the far-spread sea
Beneath its shining surface comprehends.
A fiery energy and heavenly source
Are theirs, though evil bodies counteract,
And earthly limbs and members that must die.
Hence 'tis they fear and hope, they mourn and joy,
Though heaven they see not from their prison dark.

Some apology is needed for venturing to translate a passage differently from that best and most eloquent of translators, Dryden: but in this case he is too free in his rendering, and has permitted poetic feeling somewhat to take the place of close accuracy.

[4] The Chev. Bunsen remarks, "we must expressly warn our readers against a misunderstanding into which Egyptologers, from Champollion downwards, seem in danger of falling. He was perfectly right in considering it a matter of great importance to notice those groups of gods which are ordinarily found together. Now, as a principal god is very frequently met with in the temple-representations, conjoined with two others, in his letters from Egypt he formed out of these a series of so-called Triads, an idea which Rosellini and even Wilkinson have taken up, and carried out still farther. Upon this, it is first of all to be remarked that these groups often vary, and further, that they are not formed of gods of the same order, so that they can furnish us no sort of assistance in restoring the three orders." It must be observed, however, that Chevalier Bunsen, had he visited Egypt, would have seen that triad-worship was rather the rule than the exception, judging from the representations on the monuments. It should also be noted, that if the orders were, as he holds, indicative, not of the position of the gods in the Pantheon, but of the rank of the towns where their worship prevailed, then the inferior divinity or divinities of a triad would almost necessarily have been of another order than the greater, as their local worship was of less importance; so that an argument is thus afforded in favour of triads rather than against them. Chev. Bunsen continues, "We must also protest, in the name of philosophy, against the abuse of the word triad. Three times one certainly make three, but not a trinity complete in itself, still less a trinity which is at the same time a unity. The true idea, which must be considered as the origin of the formation of triads, certainly lies much deeper, and is assuredly not to be found in this manner upon the surface. This is especially the case, if, as has been the practice hitherto, we do not distinguish any epochs, but consider the representations of a period of 3000 years (during which two immense revolutions in the religious sentiments of the Egyptians can be historically demonstrated), as forming one single original system" (*Egypt's Place*, vol. i., pp. 365, 366). The learned author does not seem to have sufficiently borne in mind that in many heathen systems a triad originated from a monad, and that the Egyptian triads were formed of cognate personages.

[5] Manetho, cited by Plut., *De Is. et Osir.*, c. 9. Comp. Iamblichus, *De Mysteriis*, viii., 3. Bunsen's *Egypt's Place*, vol. i., pp. 63, 370.

[6] Mr Birch suggests "who is male and female," a probable rendering.

Egypt.

evidently were intended to contain nothing indecent, whence we may reasonably suppose that the ceremonies were likewise free from intentional indecency. We must be particularly careful in receiving what was written of the Egyptian religion by those who were unfriendly to it or positively inimical, at a time when it had been much corrupted by Greek and Roman influence; and we must not receive the stories of passing travellers without caution because they lived two thousand years ago, when indeed it was more difficult to obtain accurate information, and the educated class was more credulous than now. Khem is usually accompanied in the sculptures by a stand whereon are representations of trees and of a flower, or a single flower.[1] This exactly corresponds to the asherah or idolatrous grove mentioned in the Bible. The "groves," however, were sacred to Baal, and the Egyptians called Seth Baal, and not Khem. The cause of this may be, that Baal was the chief divinity of many of their enemies, and that the Egyptians were therefore more ready to consider him the same as Seth, or physical evil, than as Khem, the personification of productiveness, and in some sense of physical good.

Ptah.

Ptah, or Phthah, the god of Memphis, is one of the most important personages in the Egyptian Pantheon. He has two ordinary forms; the one that of a mummy-shaped male figure, holding in his hands a long and complex sceptre; the other that of a pigmy or child, with a large head.[2] In the latter form he was worshipped at Memphis, if we may decide from the account of Herodotus,[3] and the number of small figures which have been found of Ptah as a pigmy on the site of that city. The temples have been so entirely destroyed, that we cannot judge of the worship of Memphis as we can of that of Thebes and many of the other towns of Egypt. The pigmy Ptah generally received the name Ptah-Sokari-Osiris (an appellation which connects him with Osiris, the judge of the dead), and has been supposed to be the same as the Phœnician πаταικος.[4] He was held to be the demiurgus or creator of the universe,[5] and is thus connected with Kneph, and Seb, the father of Osiris.

Neit or Neith.

The goddess Neit or Neith is often associated with Ptah.[6] She was the chief divinity of the ancient and famous city of Saïs in the Delta; and the Greeks relate that Cecrops, leading a colony thence to Athens, introduced her worship into Greece, where she was called Athena. This Greek name may be derived from the Egyptian, if we suppose the latter to have been sometimes pronounced Thenei, with the article prefixed; and the name of the goddess of truth and justice, Ma-t or Ma-th, may have been in the same manner the original of Themis. She is represented as a female having upon her head the crown of Lower Egypt, or the initial and chief character of her hieroglyphic name, supposed to be a shuttle.[7] She appears to have been a female form of Ptah. The fact of her being the chief divinity of Saïs, shows that it was not necessary that the most important person of a triad, or the principal object of worship, should be a god, and other instances support this view.

Ra.

Ra, or the sun, was worshipped at Heliopolis as chief god, and in many other places as a cotemplar divinity. His usual figure is that of a man having a hawk's head, upon which is placed the solar disk and the royal asp.[8] Sometimes he was adored as the solar disk Atin-ra, an object of worship pourtrayed in the form of the sun, whence issue numerous rays terminating in human hands, one of which gives the sign of life to the person supplicating.[9] This form of Ra is, however, almost entirely confined to the monuments of a foreign race of sun-worshippers, whose religion and history belong to a subsequent portion of this article.

Thoth.

Thoth, the god of letters, was especially regarded as the patron of the town of Hermopolis Magna, in Middle Egypt. His usual form is that of a man having the head of an ibis, and often bearing the crescent and disk of the moon; the latter, however, being distinguished from that of Khuns by its elongated and depressed form.[10] He presided over science, art, and every mental pursuit, and hence his position among the Egyptians was very high; and Hermes Trismegistus, a form of Thoth, has scarcely ceased to be regarded as a mysterious and powerful personage from the connection of his name with magic.

Atum.

Atum, and Pasht, or Pakht, were children of Ptah. The former was an important divinity with respect to the deceased, but inferior to Osiris. He is pourtrayed as a man, often wearing the crowns of Upper and Lower Egypt.[11] His sister Pasht, who is sometimes styled his mother, was called Bubastis by the Greeks, who identified her with Artemis (Diana), and was the goddess of the town Bubastis, in Lower Egypt. She is usually represented as a lion-headed, or cat-headed female, having the globe of the sun, and an uræus upon her head.[12] A great festival was annually held at Bubastis in her honour, whereof Herodotus gives some account.[13] Her offices are not clearly made out.

Pasht, or Bubastis.

The children of Ra were eight in number. Among the most important of these were the goddesses Athor or Hathor, and Ma-t or Thma. The former of these was identified with Aphrodite by the Greeks. Her name signifies "the abode of Horus," and she is pourtrayed as a female having a cow's head with a globe between her horns, or a human head above which are the horns of a cow and a globe and uræus.[14] She was the goddess of beauty and mirth,[15] and her worship was very prevalent in Egypt. The town of Tentyris (Dendera) was under her protection, and a magnificent temple to her yet stands there. Her name connects her with Isis, the mother of Horus.

Athor.

Mu and Ma-t.

The god Mu, and goddess Ma-t, brother and sister, would seem to be male and female personifications of one and the same principle; for each wears on the head the ostrich feather, and that is always the chief sign of the name of the former, and the symbol and sometimes name of the latter.[16] Mu is solar light, and Mat the goddess of truth and justice, and it seems therefore most probable that the former represented physical light, and the latter moral light. That the male divinity should personify physical excellence and the female moral, is remarkable, as indicating a philosophy which acknowledged that while man was more powerful of body, woman possessed a soul of greater delicacy and more capable of religious feelings.

Tafnet.

Tafnet and Munt must also be noticed as children of Ra. The former has the head of a lioness, and may be regarded as only another form of Pasht;[17] and the latter is represented as a hawk-headed figure having a disk and uræus on his head, above which rise the high plumes of Amen.[18] He appears to have corresponded to Mars, and the king is likened to him when he is waging a successful war against the enemies of Egypt, of which country Munt was regarded as a protector. Another son of Ra was Sebak, who is usually depicted with the head of a crocodile, and a head-dress composed of ram's horns, a disk and two ostrich feathers.[19] His offices are not as yet ascertained.

Munt.

Sebak.

Seb.

Last of the children of Ra, Seb and Nutpe must be mentioned as the heads of the Osirian group of divinities. Seb

is represented as a man upon whose head usually stands a goose, which is also the initial letter of his name.[1] It refers to his character as creator, in which he is likened to a goose producing the egg so famous in the Orphic writings.[2] He is thus connected with Ptah, to whom the office of creator is likewise assigned. Nutpe, the consort and sister of Seb, is represented as a woman having sometimes upon her head a small vase, her symbol and the initial of her name.[3] That name is believed to signify "the abyss of heaven." She is stated in the hieroglyphics to have been the parent of the gods, like Seb, and she presided over the soul.[4] From these two sprang Osiris and Isis, Seth and Nephthys, and Aroëris.

Osiris.

Osiris is the most remarkable personage in the Egyptian Pantheon, and was probably more highly reverenced than any of the other gods. His usual form is that of a mummied figure holding the crook and flail, and wearing the crown of Upper Egypt, generally with an ostrich feather on each side.[5] He was regarded as the personification of physical and moral good, and hence one of his commonest names, Un-nufre, signifies "the opener" or "revealer of good things."[6] He is related to have been on earth instructing mankind in useful arts, to have been slain by his adversary Typhon, by whom he was cut in pieces, to have been bewailed by his wife and sister Isis, to have been embalmed, to have risen again, and to have become the judge of the dead, the righteous among whom were called by his name and received his form, in which indeed they are always represented. Although in this extraordinary story we may possibly trace a physical meaning, yet the moral meaning is far more prominent; and the intention appears rather to point to the struggle between moral good and moral evil, than between physical good and physical evil. Indeed, although the opponent of Osiris personified both physical and moral evil at a comparative late period, there is strong reason for supposing that such was not originally the case; and it is therefore not probable that the story of Osiris was intended to typify the opposition of good of both kinds to evil of both kinds. Admitting, then, that it teaches the doctrine of the conflict between moral good and moral evil, it is to be inquired why this doctrine was embodied in so remarkable a narration. Considering all the points of resemblance—bearing in mind that mankind must have been granted a primeval revelation, and what evidence of there having been such a revelation is afforded by the great doctrines of the immortality of the soul, the resurrection of the dead, judgment to come, and future rewards and punishments, all so closely interwoven with the story of Osiris—carefully weighing all this, it seems an unavoidable conclusion that this story is derived from some prophecy of the remotest times respecting the future Saviour of mankind. The discovery of this remarkable analogy was made some years since by Mr Lane, and a careful comparison of all the hieroglyphic documents which bear upon it in our hands, has afforded it a complete confirmation.

Isis.

Isis, the consort of Osiris, was scarcely less venerated than he, and shared the honours of his temples at the sacred city of Abydos and the holy isle of Philæ. She is usually represented with a small throne, her symbol, on her head, and more rarely with the globe and cow's horns as a head-dress, and sometimes as winged.[7] She is connected with Athor both in her figure and some of her offices, &c. She mourned over the dead, presided over the funeral rites, and was present, as well as Nephthys, with Osiris at the judgment of the dead. Her titles were so numerous that she received the appellation of Myrionyma, or one having ten thousand names.

Set, or Typhon.

Set, or Seth, called by the Greeks Typhon, was the brother of Osiris, and the personification of physical evil. He was represented as having the head of a fabulous animal, with a long snout and high square ears.[8] He was worshipped until at least the close of the Twentieth Dynasty, but after that period his figures were erased from the walls of the temples, even when forming part of the names of kings. This change is conjectured, with great ingenuity, by the Chevalier Bunsen to have been effected by the kings of the Twenty-second Dynasty, who were, partly at least, of an Assyrian or Babylonian origin.[9] Among the Persians and the neighbouring nations the doctrine prevailed that all good was traceable to the good principle and all evil to his opponent. Hence hard drinking was esteemed among the Persians a virtue, and calamities were not received as either ordained of the good principle or permitted by him. With the introduction of this doctrine into Egypt, Seth was at once expelled the Pantheon, and thenceforward regarded as the personification of both physical and moral evil, instead of being held to be a good being.[10]

Apep, or Apophis.

The only representation that we find of moral evil is that of an enormous serpent called Apep, which was, in the Greek form, Apophis. The gods are pourtrayed in the mystic subjects on the walls of the Tombs of the Kings at Thebes engaged in warfare with this monster, whom they ultimately destroy.[11] Moral evil being represented by a serpent, affords another link in the argument that much of primeval revelation was retained, more or less distorted, by the ancient Egyptians.

The consort of Seth was Nephthys his sister, called in the hieroglyphic inscriptions Nebt-hi, whose figure is that of a female having upon her head either her symbol, a basket and house, or the cow's horns and globe.[12] She much resembles Isis, and there can be little doubt that she stood in the same relation to Seth that Isis did to Osiris, being merely a female form of the male divinity. The monuments have afforded no light on this matter, but although not expelled with Seth, the statements of Plutarch[13] show that she was regarded as the barren condition, and in some sort destructive power of nature. We can, therefore, scarcely suppose with Bunsen that this explanation of the personification can be the result of the late notions respecting the story of Osiris.[14] Like Isis, she presided over the funeral rites, and was present with her at the judgment of the dead.

Har-oër, or Aroëris.

Aroëris is called in the hieroglyphics Har-oër, or the Elder Horus. He is represented as hawk-headed, and wearing the crowns of Upper and Lower Egypt.[15] In one character he was called Har-Het, Horus of Het or Adfoo, Apollinopolis Magna, and by the Greeks Agathodæmon, having the usual form of Aroëris, or that of a winged globe. He thus corresponded to the Feroher of the Persians, or the protecting good genius. It is very difficult to distinguish between Aroëris and Har the Younger, or Horus: indeed there is so much connection between these two divinities and Harpocrates, that they must be regarded as simply different forms of one personage.

Har, or Horus.

The children of Osiris and Isis require the next notice: they were Har, or Horus, Har-pi-chruti or Harpocrates, and Anup or Anubis. The god first mentioned was represented as Aroëris, hawk-headed and wearing the crowns of Upper and Lower Egypt.[16] He was distinguished, like Osiris, for

Egypt.

his part in the strife between good and evil, in which he assisted his father, as well as in the judgment of the deceased, whom he conducted before him. To his brother Anup, or Anubis, the jackal-headed god,[1] was assigned the weighing of the souls of the departed in the judgment, and he especially presided over embalming and funeral rites. He and another jackal-headed god, Hepu-her,[2] who was also connected with the future state, were the guards of the paths of the sun, which would seem to indicate a cosmic character, but they are probably so called in relation to the cycles of the future state. Harpocrates, in the hieroglyphics, Har-pi-chruti, or Horus the Child (a reading and etymology which we owe to the ingenuity of Bunsen, aided by Lepsius[3]), is represented as a naked boy wearing a side-lock, and sometimes the crowns of Upper and Lower Egypt. He is often pourtrayed seated upon a lotus-flower, and with his finger in his mouth, not to denote silence, but a childish action, as Sir Gardner Wilkinson has justly remarked.[4] Osiris was likewise parent of the four genii of Amenti or Hades, who were supposed to protect the parts of the body which, being not embalmed, were placed in jars, bearing the names of these genii, and having lids in the form of their heads.[5]

Anup, or Anubis.

Hepu-her.

Har-pi-chruti, or Harpocrates.

Several other divinities might be mentioned, but those enumerated above are the most important. The androgynous Nilus, who has been already described in an earlier portion of this article, and the goddess Seben or Lucina,[6] who was especially held to protect Upper Egypt, may be particularized. There are not, however, many more divinities, several which have been supposed to be distinct being merely different forms of those before described, while others must be regarded as foreign, or as merely mystical, and having no place in the Pantheon.

Hapi-mou, or Nilus. Seben, or Lucina.

Animal-worship.

The distinguishing peculiarity of the ancient Egyptian religion, with respect to worship, is the adoration of sacred animals as emblems of the gods. It was a custom of great antiquity, for Manetho tells us that in the reign of Chaiechôs, the second king of the Second Dynasty (about B.C. 2400), the bulls Apis at Memphis, and Mnevis at Heliopolis, and the Mendesian goat, were called gods.[7] This shows not only that the Egyptian religion was not wholly developed until that time, or later, but probably that animal worship was unknown in the most ancient form of that religion. Afterwards, however, this strange custom had become so prevalent that we find at the time of the Eighteenth Dynasty (about B.C. 1525–1340) one animal at least sacred to every god, and no city without such an object of worship. No satisfactory cause has been assigned as the origin of this superstition, as it has been the endeavour of those who have written respecting it to furnish a philosophical explanation of an unphilosophical custom. The existence and popularity of such worship proves, however, whence it originated; for the desire felt by mankind for a living or material object of adoration has in all ages led priests to offer them something to satisfy this desire, by giving them a material representation of a divinity, and the common people have entirely lost sight of the immaterial in the material, while their instructors have not been willing to undeceive them, and thus lose a source of wealth and influence.

Of certain if not all of these animals, one was always held especially sacred, and during its lifetime received peculiar honours, and at its death a magnificent funeral. The most celebrated of these were the bulls Apis at Memphis and Mnevis at Heliopolis, both sacred to Osiris, though some say the latter was sacred to the sun, and the Mendesian goat—which three Manetho mentions as having been made objects of worship at the same time. Of the sacred animals generally a mere enumeration must suffice, in the order of their importance, as nearly as can be ascertained. The most important seem to have been bulls, sacred to Osiris, and cows, to Athor; a kind of hawk, to Ra and other gods; the ibis, to Thoth; the crocodile, to Sebak; the asp, to Num and the goddess Rannu; the cat, to Pasht; the scarabæus (beetle), to Ptah and Ra; and the goat, to the god called Mendes by the Greeks, whoever he may be. As of secondary rank may be mentioned the ram and sheep, sacred to Num; the cynocephalus, to Thoth; the cerastes, to Amen; the jackal, and probably more than one allied species, to Anubis; a great vulture, to the goddess Seben; the kind of heron called in the hieroglyphics bennu, to Osiris; and five kinds of fish—the oxyrhinchus, the latus, the lepidotus, the phagrus, and the mœotes, the first of which was sacred to the goddess Athor.[8] Among the animals of the least note may be remarked the lion, sacred to Hercules or Mu; the shrew-mouse, to the goddess Buto, whoever she may be, and the ichneumon. From this enumeration, which is taken from the list and excellent account of the sacred animals by Sir Gardner Wilkinson,[9] it is evident that the selection of many of them must have been inconvenient, and that of others dangerous, so that it is vain to endeavour to trace wise motives in their choice. None of the animals, except some of those selected from their fellows, such as the bull Apis, received more than a local veneration, and some of them were as much execrated, or as little respected, in one nome, as revered in another.

Sacrifices.

The worship of the Egyptian divinities was conducted with much ceremony and mystery. The objects sacrificed or offered were animals of various kinds, and parts of animals, vegetables and fruit, first-fruits of the corn, libations of wine, and incense. There is no representation of an undoubted human sacrifice on the Egyptian monuments. The king is sometimes pourtrayed slaying a group of foreign captives before a divinity, but the accompanying inscriptions render it most probable that the subject has merely a symbolical meaning, being intended to signify the destruction of enemies generally. Manetho, however, related that the custom of human sacrifices in Heliopolis was abolished by Amosis, almost certainly the king having that name who is the head of the Eighteenth Dynasty;[10] and Plutarch says, on his authority, that such sacrifices were performed in the city Eilethyas.[11] The human sacrifices at the latter place were probably abolished, like those at the former, in early times. Magnificent temples, some of which will be described in a later part of this article, were raised in honour of the gods, and a numerous body of priests was engaged in their service.

The future state.

The most interesting aspect of the religion of ancient Egypt is in its influence on the people. Man was held to be accountable hereafter for his actions done in this life, and to be judged or condemned according to his works. He was to be brought before Osiris, and his heart weighed against the feather of truth; he was to be questioned respecting his actions by the forty-two assessors, as to whether he had committed the forty-two sins concerning which they inquired. If guiltless, he took the form of Osiris his judge, and entered into a state of happiness, living among the gods in a region of perpetual day, by the banks of the celestial Nile; but if guilty, he was taken by ministers of vengeance, sometimes changed into the form of some base animal, such as a sow,[12] and consigned to a fiery place of punishment and perpetual night. It is not certain whether the judgment was believed to occur at each man's death, or generally at a remote future period; nor whether the

Egypt.

rewards and punishments were believed to be of eternal duration, but the soul was held to be immortal. Many good results of these important doctrines can be traced, but they were unfortunately neutralized by the baseness of the idolatry, so that we can only detect the effect on the mind in accustoming it to think of eternity, and thus giving it sublime ideas, while the soul was debased from true religion by the superstitions and allegories wherein what the Egyptians possessed of it was hidden.

Origin of religion.

From the preceding account of the Egyptian religion, some opinion of its origin may be deduced. We trace in it certain well-defined relics of what can only have been a primeval revelation; we observe a strong Sabæan element, particularly as the verb "to adore" is expressed by the symbol of a man in an attitude of worship to a star; we find much of a cosmic religion or nature-worship, besides Sabæism; and, lastly, we remark an intellectual polytheistic system in the adoration of abstract intelligences. Hence we must conclude that this religion had at least a triple origin; but having been evidently comparatively complete at a very remote period, coeval with the earliest inscribed monuments now remaining, or antecedent to them, we cannot attempt to guess the manner in which its sources became moulded, and the time which was occupied in this being effected.

Laws.

The monuments tell us little respecting the laws of the country, and that little is gathered inferentially. Ancient writers in some measure supply this deficiency, as far as we can venture to rely upon their statements.—Some of the kings were celebrated as lawgivers, as were also the gods, and especially Thoth or Hermes.

The laws respecting crimes and offences must have been generally severe in their nature, and unbending in their application, as the sculptures show that men and women of all classes went for the most part unarmed and unprotected. Now, it is usual in the Turkish empire to see the ploughman with pistols in his belt, and a gun over his shoulder, or at least armed with a dagger or a heavy staff. Murder was punished with death, whether the person killed were a free man or a slave, but otherwise capital punishment was sparingly inflicted. Indeed, at one time, under the rule of Sabaco the Ethiopian (of the Twenty-fifth Dynasty of Manetho), according to Herodotus,[1] who may mean the whole Ethiopian dynasty, the king's power of commuting the sentence was exercised in all cases of persons capitally condemned, and the culprits were employed to raise the mounds on which their cities stood. Adultery was punished by the man being beaten with a thousand strokes of rods, and the woman's nose being cut off. Forging of money and deeds, and similar crimes, were punished by the loss of both hands of the guilty person. Theft was not regarded as a heinous offence, if we may believe Diodorus, but this can only apply to petty theft. The common punishment for this and such like breaches of the law was beating with a stick; and the right thus to chastise was permitted to masters and all persons of authority, to ensure the obedience of inferiors, and avoid the inconvenience of having to refer all causes to a legal tribunal. Respecting debt, king Bocchoris, surnamed the Wise, of the Twenty-fourth Dynasty, enacted that if a man were sued for a borrowed sum of money by one who produced no written agreement, he should be quit of the debt if he denied having borrowed on oath. Usury was not permitted to the lender above what would double the sum lent, and payment was taken from the debtor's property, but it was not lawful to imprison him. Of the laws relating to the tenure of land mention has been made in an earlier place. It may be repeated here, that under Joseph's administration the whole of the land, except what belonged to the priests, became the property of the king, but that it appears that the military class soon regained possession of their lands.[2]

Government.

The government of Egypt was of the monarchical form, but limited so as by no means to deserve the character of a despotism. The will of the king was restrained by the power and wisdom of the priesthood, into whose class he was admitted, though not as head of the religion, on or before his accession. The priests could refuse an unjust king the rites of burial, for every one was judged before those rites were permitted to be performed; and there is no doubt that in other ways they restricted the unlimited exercise of regal authority. The power of various kings was, of course, more or less despotic, but on the whole it does not seem to have been unreasonably exercised; and the greatest of them appear generally to have been regarded as benefactors by the common people, if we except, perhaps, the builders of the Great Pyramid and of the Second. The government of the country under the king was administered by nomarchs or governors of nomes, and toparchs or governors of toparchies, into which the nomes were subdivided, as well as minor officers. Some of these seem to have been hereditary rulers, and those of Eilethyas appear at one time to have been not only hereditary but of royal descent. The governor of Ethiopia, under the Pharaohs of the Eighteenth and Nineteenth Dynasties, always received the title, "Prince of Cush," and was probably a kind of viceroy. The king's sons do not seem to have been made governors, although they commanded bodies of troops, and held court appointments.

Domestic life.

The subjects on the walls of the ancient Egyptian tombs give us a great insight into the domestic life of that people. Of their infancy and youth we know little, but it is evident that boys were trained to manly sports and exercises, and educated to read and write, as well as instructed in their religion. Circumcision was practised from the earliest periods, but it does not appear whether it was considered a religious rite. On attaining to manhood they married, and appear to have restricted themselves to but one wife. Diodorus Siculus relates that, while the priests were allowed but a single wife, the rest of the people were permitted to marry as many as they pleased.[3] If such were the case, this privilege was very rarely taken, and the monuments have not as yet afforded a decided instance of it. No marriage ceremonies are represented, as far as is known, but the state was evidently considered honourable and binding. Concubines were allowed, and their children, though acknowledged, were probably held to be inferior to those of wives. The women, doubtless, received a lower education to that of the men, but not so much so as among the modern Egyptians. They were not restrained by any system resembling the hareem-seclusion of El-Islâm, and always mixed freely with the other sex. Those of the upper classes were treated with marked respect; the wife being called the "lady of the house," and held in all respects to be her husband's equal. Among the poor, the wife was very subject, as in all other countries. There was also no separation into castes, as has been supposed, and we can only distinguish the classes of soldiers, priests, and labourers. These were not prohibited from intermarrying, and sometimes a man held both a military and a sacerdotal appointment.[4] There were no hereditary titles, although some families appear, or one, at least, to have possessed a hereditary government, as above mentioned. In these circumstances, therefore, it is not to be wondered that the condition of society was flourishing, and the intercourse of the people for the most part comparatively liberal and friendly. Foreigners, however, were regarded with dislike and jealousy, perhaps especially after the rule of the Shepherds. The

[4] M. Ampère first proved that the Egyptians were not divided into castes.

Egypt.

lower class being uneducated, and for the most part very poor, seems to have been despised by the higher; and the agricultural labourers and herdsmen appear to have been regarded with particular contempt. The servants were chiefly free Egyptians, but were sometimes negro and other captives.

Entertainments.

The rich were very hospitable, delighting in giving feasts at which the guests were provided with very varied entertainment. The host and hostess sat together, as did other married people, and the rest of the company were arranged in various ways, the men and women generally being seated apart. The seats were single or double chairs, but many sat on the ground. Each guest was adorned with necklaces of flowers by the servants, and a lotus flower was bound to the head, on which was likewise placed a lump of ointment. Small tables were set before them, whereon were piled meat dressed in many ways, fruits, cakes, and other viands, and wine-cups were carried round. Before the repast, hired musicians and dancers amused the company, and often the entertainment seems to have been solely music and the performances of dancers, the guests being offered wine and flowers, and anointed.[1] The ancient Egyptians had many other amusements, such as various games, one of which resembles chess in appearance, but probably is rather to be likened to the game of draughts, and they were diverted by dwarfs, and the male and female performers of various feats.[2] Of their everyday life the sculptures give us some idea. The proprietor of land and cattle went out in the morning and superintended agricultural processes on his estates, such as sowing or reaping; or he saw the flocks and herds brought before his scribes to be registered. Sometimes he directed the shipment of his produce for some town, or went to view the fisheries. When he was at liberty he diverted himself by going among the fenny tracts in a canoe, generally with some of his children of both sexes, to spear the hippopotamus, or more frequently to knock down birds with the curved throw-stick. At other times he fished with a line in the preserves of his gardens or lands, or went to the desert, generally a-foot, to hunt various animals of the antelope kind, which he shot with arrows, often stone-tipped, sometimes coursing with hounds.[3] Every man of the better classes had a chariot, generally drawn by two horses, which he usually drove himself, standing in it. The life of the ladies was not unlike that of the men, except that they did not join in the sports, but sometimes as spectators. They seem to have spent their time principally in household matters, in visiting, and walking in the gardens. Occasionally they rode in heavy chariots drawn by oxen. Their manners seem to have been indolent and luxurious, and in these respects similar to those of the modern inhabitants of the same class, unlike the men who were so much more active than those of the present day. Among the lower orders the men were employed as labourers and artisans, while the women were engaged in work which was generally lighter than that of the other sex. Both led hard lives, having scanty clothing and poor food; yet the cheapness of living, and the mild climate, rendered their condition easier than one would at first suppose.

Games.

Sports.

Language.

The language of the people was that which has been called the Egyptian, and in its later form, after the people had become Christians, the Coptic. The Egyptian was kindred to the Syro-Arabian class, though not actually belonging to that group. At least two dialects appear to have prevailed, which we find in the Coptic, besides a third: these are the ordinary Coptic or Memphitic dialect, that of Lower Egypt; the Sahidic or Theban, that of Upper Egypt; and the Bashmuric, prevailing in the Bucolia, and perhaps the Oases. The last-mentioned may therefore be almost considered as provincial. The language was monosyllabic in its roots, and abounding in vowels. Its sound must have been somewhat harsh if the Copts have rightly retained the pronunciation. The inscribed and written character was the hieroglyphic, an extremely complex system, which expressed words partly by representations of objects and symbols of ideas, and partly by signs which denoted phonetically all or the chief letters of a word. From this was formed the hieratic, which is but a running hand or common written form of the other, in which documents were usually written on papyrus, and from which sprang another system. This last was the demotic, or enchorial writing, composed of a few characters selected from the phonetic signs in hieratic, usually two to each letter, and more simply written, forming a convenient system of writing for deeds and other legal documents, as well as for ordinary use among the people. The hieroglyphic and hieratic writing, we find to have prevailed at very early periods; the former is found on monuments of the age of the Great Pyramid (B.C. 2400), and the latter in the time of the Ninth Dynasty (about B.C. 2100). The demotic appears to have been introduced at a comparatively late period, as we find no examples of it earlier than under the Twenty-sixth Dynasty; and it did not come into general use until the period of Greek and Roman rule. For further details on this subject, the reader is referred to the article HIEROGLYPHICS.

Literature. Papyri.

Much remains to us of the literature of ancient Egypt. Numerous papyri have been discovered containing religious and historical documents, the former generally in hieratic, the latter always, and these with the inscriptions of the tombs and temples, as well as of almost countless tablets, afford us specimens of the character of this literature. The religious papyri are all portions or complete copies of one work which Champollion entitled "the Funeral Ritual," and Lepsius "the Book of the Dead."[4] This is a strange rambling composition, which some have supposed to be a collection of various pieces of different ages (a hypothesis that must be cautiously accepted, as it is such a favourite one of German criticism, often used to explain what needs no explanation of the sort), and divided into many chapters headed by rubrics. It consists of a series of prayers to be said by the soul during its wanderings after death until reunited to the body, and instructions as to what will happen in this intermediate state. Although much study has been bestowed upon it, its contents have not been understood in detail; which is owing partly to the use of words which are not found in the Coptic, having been abandoned at the conversion of the Egyptians to Christianity, and partly to the extreme obscurity of the subject. It has not been found to contain any passages of eloquence or beauty, and as a composition is certainly most disappointing. The religious inscriptions are often portions of this great work, but many are simply addresses to the gods, or lists of their titles. The historical papyri do not much, if at all, excel the religious in the matter of composition, though far exceeding them in the interest of their subjects. Some of these are a kind of poetical account, probably in measured prose, if not in verse, of the exploits of the king of Egypt, while others are merely narratives of various matters from one official to another.[5] The historical inscriptions are generally inflated panegyrics of the king, relating the overthrow of his enemies and other great actions of his reign, whether civil or mili-

Egypt.

tary.[1] Some moral sayings have been discovered, and one romance, of which the Vicomte de Rougé has published a very interesting account.[2] It is full of curious incidents, and displays a most remarkable supernatural machinery. A complete translation of this and other works of the same kind, should they be discovered, would furnish us with much curious matter, and, in particular, throw light upon the question as to how much of the superstitions of the Arabs and modern Egyptians, and their fairy mythology, may be traceable to the ancient people of Egypt. It is also to be hoped that the books relating to sacred ceremonies, to laws, to arts and sciences, and the like, or some of them, may be recovered, and that we may thus be enabled to form a tolerably fair estimate of the state of literature, science, and art among this remarkable people.

A romance.

Science.

Respecting the sciences we have chiefly to depend upon the evidence founded on the monuments, and some of the sculptures and inscriptions which remain—evidence which is therefore partly inferential, and when direct, is only based on incidental data. It is nevertheless of the most satisfactory character, and corroborative of the accounts of ancient writers. Astronomy was the chief of the sciences, and it was carried to the highest point which it could attain without the aid of modern instruments. In order to determine the length of various periods, and the times at which certain religious ceremonies should be celebrated, a very accurate observation of the heavenly bodies became necessary; and the belief that these bodies influenced the wellbeing of mankind induced the most careful registry of their movements, and in particular of those phenomena so difficult to observe, the heliacal risings of stars. It has been asserted by ancient writers, and modern scholars have supported their statements, that the Egyptians, besides being acquainted with the Julian year, had even ascertained its inaccuracy as a tropical year, having attained to a knowledge of the precession of the equinoxes.[3] When we consider the long period through which their observations must have been carried on, and that the Greeks must have discovered this doctrine if they did not derive it from the Egyptians or Chaldees, without being more favourably placed, such an opinion seems in nowise unreasonable. Geometry held the next place to astronomy. The necessity of measuring the height of the rise and inundation of the Nile, the construction of dams and dikes, and many such like matters, must have required a knowledge of geometry and the kindred sciences quite as much as mechanical skill; and we find that the ancient Egyptians were famous in these branches of science, which, indeed, is sufficiently attested by existing works. Their mechanical skill is remarkably evidenced by the construction of the pyramids of Memphis at a very early period of their history. The transport of part of the materials for these structures from quarries on the opposite bank of the Nile, of part from those of Syene, nearly 550 miles above Memphis by the course of the river—the transport of such masses of stone by water and land, the elevation of the blocks, some of enormous size, while the buildings were in progress, the beautiful fitting of the polished masonry, and the accurate excavation in the rock of part or all of the passages and chambers, show a very great mechanical knowledge, the results of which have not been excelled by that of Europe at the present day. With chemistry the Egyptians must have possessed considerable acquaintance, as we may conclude from the state of various arts which in a great measure depend upon it. The workers in metals used the blow-pipe, and made knives of steel, though these and swords were usually of a *hard* bronze; and the manner in which Moses destroyed the golden calf is an evidence of the chemical skill of the Egyptians, from whom it is reasonable to suppose he had acquired the knowledge of which he then made use. Medicine and surgery, including anatomy, were much studied, and attained a high degree of excellence relatively speaking. Of the purely abstract sciences we can scarcely judge, and it is dangerous to reason from the character and religion of the people.

Arts: architecture.

Of the arts architecture claims the first place, painting and sculpture being subservient to it among the Egyptians. Temples were not raised to contain statues, but statues were set up to adorn temples whereof they formed architecturally a part, and the walls were decorated with painted sculptures and paintings, which again formed parts of the architectural whole. The group of these arts may therefore be considered as one, and it should be our object to discover the grand principle which was intended to be expressed by the Egyptians in their application of them. Their houses were slight and temporary; they cared only for two classes of edifices, temples and tombs; the former as abodes of the gods, the latter as resting-places for bodies they deemed sacred and to be preserved for ever. In both the builders aimed at solidity of material, massive grandeur of form, richness and sobriety of colour—that they should last for ever, and express at once the solemnity of the present and of the future. The idea that originated this architecture was the contemplation of eternity and of the immortality of the soul; and in recognising that idea, and the noble manner in which it was carried out, we find something great and admirable in the ancient Egyptians. If we compare the same arts of Assyria and of Greece, we trace a far different leading idea. In Assyria the greatness of the king as the vicegerent of the gods is constantly brought before us; his figure crowds the temple walls, where the gods are ever represented protecting him, and he rarely offering to them, while in Egypt the king is constantly pourtrayed worshipping and sacrificing, and not so constantly attended by the gods. In Assyria the palaces contain temples, but in Egypt the temples are palaces. In Assyria, and afterwards in Persia, the great king was the one object of respect or fear; and when the Persian princes introduced that famous edict, that none was to ask a petition of any god or man for thirty days save of the king only,[4] they were but carrying into effect what had been virtually practised by almost all the people; and their being able to procure such a decree sufficiently proves this. The leading idea then that influenced the Assyrian artist, was the majesty of the king. In Greece we see another leading idea. However it may have been in older times, at the best period of art among the Greeks, we perceive that sculpture, which was their highest art, was designed to express the perfection of human beauty, not ideal beauty, as it has been called, but a perfect form composed, like the famous picture of Zeuxis, from a study of the most beautiful human examples. The architecture expresses the same idea; it is always symmetrical, elegant, pure in taste, but never massive or sublime. The leading idea here is beauty, and that of a material kind. In ancient art, therefore, the Egyptian has the highest place with respect to intention, and equals that of Greece and Assyria in the excellence with which the intention has been carried out. He who has been pleased with the temples of Greece and interested with the palaces of Assyria, is confounded by the Great Pyramid, and struck with awe in the hypostyle hall of El-Karnak.[5]

Egypt. Magic.

Egypt has always been regarded as the home of magic arts: as early as the time of Joseph there was a class of magicians, and by them was Moses opposed. The monuments have not been found to contain any distinct notice of such persons, and our information respecting them is derived from the Bible, and from the narratives of Greek and Roman writers: there are also some magical papyri of the Roman period. The magicians were interpreters of dreams and omens, and they also pretended to work wonders. They endeavoured to bring about what they desired by invocations composed in a great measure of a strange jargon, and partly of foreign words, and they even threatened to reveal the mysteries. And it is not a little remarkable, that the performances of the modern Egyptian magicians, and their reputed results, bear a strong resemblance to one of the ancient modes of working an enchantment and the effect it was said to produce.[1] Probably the magicians were of the priestly class, but magic was most likely practised by persons of all positions, not being deemed a black art. Some kinds of magic were however regarded to be unlawful, as the invocation of Typhon after he had been expelled from the Pantheon,[2] and the use of enchantments to produce illegal results.

Character.

From the foregoing observations and other data, we may gain a not inaccurate idea of the character of the ancient Egyptians. They were religious, though much given to superstition, and of a contemplative disposition; in war they were brave, without the hideous cruelty of the Assyrians; to their country they bore a patriotic affection, and were hospitable to their fellow-countrymen; in their dress they were usually simple, and frugal in their diet. On the other hand they sometimes indulged in wine to excess, and were very sensual, especially the women, as in modern times; they were much addicted to falsehood, and did not show that kindness to foreigners that they did to their own people. This last fault is however chargeable to their religious and political system.

Industrial arts.

The industrial arts were carried to a great degree of excellence in ancient Egypt. In weaving, and all the processes connected with the manufacture of linen and the like, they have not been surpassed in modern times. Their pottery was very good, and their glass is not inferior to that of the Greeks, except in beauty of colour. In the making of instruments of music, and household furniture, of vases, and various vessels of metal, alabaster, and other materials, arms, and domestic implements, they displayed equal taste and skill, and we can trace in many instances how greatly the Greeks were indebted to them for patterns and forms which they often rendered more elegant.—The agriculture and gardening have been already noticed.

Music.

In the sculptures we find representations of a great variety of musical instruments of which scarcely more than the names can be mentioned here, the multiplicity of which shows how much attention had been bestowed on music. Various kinds of harps are represented, often richly ornamented, and differing from one another in their size and the number of their strings: they were played with the hand. We also see lyres, varying in the number of strings, and played with or without the plectrum, and the guitar which always had three chords. Besides these, there were other stringed instruments for which it is difficult to find modern appellations. The Egyptians had also flutes as well as single and double pipes, the tambourine of various forms, cymbals, cylindrical maces, drums of different kinds beaten with the hands or sticks, including that called by the modern inhabitants the darabukkeh, the trumpet, and the sacred sistrum. The military music was that of the trumpet, drum, and cylindrical maces, the first of which was confined to the army; but almost all the instruments were used in the services of the temples.[3] Respecting the character of the ancient Egyptian music it is difficult even to form a guess.[4]

Musicians and dancers.

The musicians often likewise sang or danced while playing on their instruments. The dances of both men and women were of various kinds, from what might be called feats of agility to slow and graceful movements. The dancers were chiefly women, and their performances seem generally to have resembled those of the modern dancing-girls of Egypt. They wore either a very transparent and full dress of fine linen, or nothing but a narrow girdle.[5] These circumstances would give us a very low opinion of the civilization and morals of ancient Egypt, did we not find almost their parallel in modern Europe, at exhibitions which the great of both sexes especially favour by their presence.

Religious festivals.

The festivals of the gods, or panegyries, were very numerous; and some of them attracted a great number of pilgrims to the chief temple of the divinity in whose honour they were held. The most important of these were, according to Herodotus, the festival of Bubastis, at the city called after her, then that of Isis at Busiris, next that of Neith at Saïs, that of the Sun at Heliopolis, that of Latona, at the city of Buto, and lastly that of Mars at Papremis.[6] In this enumeration of the chief festivals in the order of importance, it will be observed that they were nearly all celebrated in the Delta, and none at all south of that tract except that of the Sun at Heliopolis, which indeed was situated only a little above the ancient point of the Delta. As we find Herodotus was imperfectly acquainted with Upper Egypt, and as in his time some great towns of the earlier period had fallen into decay, we may conclude that both then and in preceding times there were other great periodical festivals. The panegyry of Amen at Thebes must have been very anciently of the highest rank; and subsequently so long as Thebes was a town, it cannot have sunk to the condition of an ordinary religious festival. These great celebrations were distinguished, not only by the grandeur of the ceremonies performed and the expense lavished upon the sacrifices, but by the concourse of people who flocked to them rather to divert themselves than to perform a religious duty, and among whom every kind of amusement was unrestrainedly practised. The festivals in honour of Osiris, whereof two were annually kept, though inferior to none in solemnity, were probably less popular, as only the initiated were admitted to the mysterious rites, which seem to have been more characteristic of them than of the other festivals.

Private festivities.

We know little of the private festivities of the ancient Egyptians, and, in particular, there is no evidence of any having been usual at a marriage, the marriage-ceremony itself being, as has been previously remarked, not represented upon the monuments. The most remarkable ceremonies connected with their private life were those celebrated at a funeral.

Funeral rites.

At the time of death the period of mourning commenced, and lasted seventy-two days or a shorter time. During this time the body was embalmed and swathed in many bandages, the outermost of which was covered with a kind of pasteboard, on which were painted the features of the deceased, and various emblems and inscriptions. A mummy

firent les vieux Egyptiens; ils concevaient en hommes de 100 pieds de haut, et l'imagination qui, en Europe, s'élance bien au-dessus de nos portiques, s'arrête et tombe impuissante au pied des 140 colonnes de la salle hypostyle de Karnac."—Champollion's *Lettres*, p. 98.

[1] See a very curious fragment of a Greco-Egyptian work on magic edited by Mr Goodwin, published by the Cambridge Archæological Society, and a notice of it in the Archæological Journal, No. 41.

[2] Reuvens, *Lettres*, &c., cited *supra* p. 438.

[3] *Ancient Egyptians*, vol. ii., p. 222, *et seqq.*

[4] The reverence in which it was held, its use in the sacred ceremonies, and the numerous and very different instruments, would lead us however to suppose that music had attained no little excellence, unless indeed the priests restricted it to conventional limits.

[5] *Id.*, vol. ii., pp. 329, 390.

[6] Herod., ii., 59.

Egypt.

was thus formed, bearing the shape of a bandaged human figure, of which the form of the head and hands alone was seen. When the tomb, which had been long previously commenced, and was either an excavated grotto or stone structure, was complete, the funeral ceremony usually took place, though it was often delayed to a later period. The mummy was inclosed in a case of wood having the same shape as itself, and this was again inclosed, when the deceased was a wealthy person, within either another wooden case, or more usually a sarcophagus of stone, sometimes of the same form as the mummy, but generally rectangular, or nearly so. The mummy was then placed upon a sledge, drawn by oxen or by men, and taken to the bank of the river, or shore of a sacred lake, which was to be crossed in order to reach the place of burial. This procession by water was an important part of the ceremony. The mummy, attended by mourners, was placed in a sacred baris or boat, which was towed by another boat, and followed by others carrying mourners, offerings, and all things necessary for the occasion.[1] On arriving at the tomb the sarcophagus was deposited in a sepulchral chamber, usually at the bottom of a pit within the tomb, and offerings to the deceased and others of his family buried there were made by the relatives, as well as to the gods presiding over the future state. Visits were afterwards paid to the tomb in order to make these offerings, probably at stated periods. One tomb sufficed for each family, and sometimes for two generations; and, in the case of the poorer classes, many were buried in the sepulchral chambers of a single pit, above which was no structure or grotto. The law has already been noticed whereby every one was judged by a legal tribunal before the right of burial was permitted.

Modern inhabitants.

The modern inhabitants must now be considered. Mr Lane (1834) estimates the population of Egypt at less than 2,000,000, and gives the following numbers as nearly those of the several classes of which it is mainly composed:—

Muslim Egyptians (fellâheen or peasants, and towns-people)	1,750,000
Christian Egyptians (Copts)	150,000
'Osmánlees, or Turks	10,000
Syrians	5,000
Greeks	5,000
Armenians	2,000
Jews	5,000

and the remainder, exclusive of the Arabs of the desert, about 70,000.[2]

Sir Gardner Wilkinson (1843) computes the total at about 1,800,000;[3] but Clot-Bey (1840), not always an impartial writer, places it much higher, upwards of 3,000,000.[4] The following result of the government census, taken in 1847–8, is remarkable as showing the system of falsifying statistics for state purposes. It is copied from an official return.

Middle Egypt	591,294
El-Gharbeeyeh	529,930
El-Kalyoobeeyeh	184,240
Upper Egypt	1,190,118
Esh-Sharkeeyeh	342,509
El-Geezeh	223,554
El-Boheyreh	215,810
El-Menoofeeyeh	440,519
Ed-Dakahleeyeh	347,347
Shubra	10,116
El-Kuseyr	3,435
Rosetta	18,405
Damietta	28,922
Suez	17,399
El-'Areesh	2,347
Alexandria	143,134
Cairo	253,541
	4,542,620

Of the present population of Egypt, the Muslims constitute seven-eighths, and nearly four-fifths of that of the metropolis; and to this class, and more particularly to the people of Cairo, the following sketch of personal characteristics and customs will relate, excepting in some few cases, which will be distinguished from the rest.

Personal characteristics.

In describing the personal characteristics of this remarkable people, Mr Lane, in his admirable work, *The Manners and Customs of the Modern Egyptians*[5] (which was written just before European influence was felt in the country, and now deservedly ranks as the only book of authority on the subject), says: "In general the Muslim Egyptians attain the height of about five feet eight, or five feet nine inches. Most of the children under nine or ten years of age have spare limbs and a distended abdomen; but as they grow up their forms rapidly improve. In mature age most of them are remarkably well proportioned; the men muscular and robust; the women very beautifully formed, and plump; and neither sex is too fat. I have never seen corpulent persons among them, excepting a few in the metropolis and other towns, rendered so by a life of inactivity. In Cairo, and throughout the northern provinces, those who have not been much exposed to the sun have a yellowish but very clear complexion, and soft skin; the rest are of a considerably darker and coarser complexion. The people of Middle Egypt are of a more tawny colour, and those of the more southern provinces are of a deep bronze, or brown complexion—darkest towards Nubia, where the climate is hottest. In general the countenance of the Muslim Egyptian (I here speak of the *men*) is of a fine oval form: the forehead of moderate size, seldom high, but generally prominent; the eyes are deep sunk, black, and brilliant; the nose is straight, but rather thick; the mouth well formed; the lips are rather full than otherwise; the teeth particularly beautiful; the beard is commonly black and curly, but scanty. I have seen very few individuals of this race with grey eyes; or rather, few persons supposed to be of this race; for I am inclined to think them the offspring of Arab women by Turks, or other foreigners. The Fellâheen, from constant exposure to the sun, have a habit of half shutting their eyes; this is also characteristic of the Bedawees. Great numbers of the Egyptians are blind in one or both eyes. They generally shave that part of the cheek which is above the lower jaw, and likewise a small space under the lower lip, leaving, however, the hairs which grow in the middle under the mouth; or, instead of shaving these parts, they pluck out the hair. They also shave a part of the beard under the chin. Very few shave the rest of their beards, and none their moustaches. The former they suffer to grow to the length of about a hand's-breadth below the chin (such at least is the general rule, and such was the custom of the Prophet), and their moustaches they do not allow to become so long as to incommode them in eating and drinking. The practice of dyeing the beard is not common; for a grey beard is much respected. The Egyptians shave all the rest of the hair, or leave only a small tuft (called 'shoosheh') upon the crown of the head. * * * The general form and features of the *women* must now be described. From the age of about fourteen to that of eighteen or twenty, they are generally models of beauty in body and limbs; and in countenance most of them are pleasing, and many exceedingly lovely; but soon after they have attained their perfect growth, they rapidly decline:" the relaxing nature of the climate, and other predisposing causes, contribute to render many of them absolutely ugly at the age of forty. "In the Egyptian females the forms of womanhood begin to develop themselves about the ninth or tenth year: at the age of fifteen or sixteen they generally attain their highest degree of perfection. With regard to their complexions, the same

Egypt.

remarks apply to them as to the men, with only this difference, that their faces, being generally veiled when they go abroad, are not quite so much tanned as those of the men. They are characterized, like the men, by a fine oval countenance, though in some instances it is rather broad. The eyes, with very few exceptions, are black, large, and of a long almond-form, with long and beautiful lashes, and an exquisitely soft, bewitching expression—eyes more beautiful can hardly be conceived: their charming effect is much heightened by the concealment of the other features (however pleasing the latter may be), and is rendered still more striking by a practice universal among the females of the higher and middle classes, and very common among those of the lower orders, which is that of blackening the edge of the eyelids, both above and below the eye, with a black powder called 'kohl.'"[1] Both sexes, but especially the women, tattoo several parts of the person, and the latter stain their hands and feet with the red dye of the hinnè.

Dress.

Their dress can be but briefly described. That of the men of the upper and middle classes consists of cotton drawers, and a cotton or silk shirt with very wide sleeves. Above these are generally worn a waistcoat without sleeves, and a long vest of silk, called kaftân, which has hanging sleeves, and reaches nearly to the ankles. The kaftân is confined by the girdle, which is a silk scarf, or cashmere or other woollen shawl. Over all is worn a long cloth robe, the gibbeh (or jubbeh) somewhat resembling the kaftân in shape, but having shorter sleeves, and being open in front. The dress of the lower orders is the shirt and drawers, and waistcoat, with an outer shirt of blue cotton or brown woollen stuff; some wear a kaftân. The head-dress of all is the turban wound round a skull-cap. This cap is usually the red cloth fez, or tarboosh, but the very poor wear one of coarse brown felt, and are often without the turban. Many professions and religions, &c., are distinguished by the shape and colour of the turban, and various classes, and particularly servants, are marked by the form and colour of their shoes; but the poor go usually barefoot. The ladies wear a shirt and drawers, a very full pair of silk trousers, and a close-fitting vest with hanging sleeves and skirts, open down the front and at the sides, and long enough to turn up and fasten into the girdle, which is generally a cashmere shawl; a cloth jacket, richly embroidered with gold, and having short sleeves, is commonly worn over the vest. The hair in front is combed down over the forehead and cut across in a straight line; behind it is divided into very many small plaits, which hang down the back, and are lengthened by silken cords, and often adorned with gold coins and ornaments. A small tarboosh is worn on the back of the head, sometimes having a plate of gold fixed on the crown, and a handkerchief is tastefully bound round the temples. The women of the lower orders have trousers of printed or dyed cotton, and a close waistcoat. All wear the long and elegant head-veil. This is a simple "breadth" of muslin, which passes over the head and hangs down behind, one side being drawn forward over the face in the presence of a man. A lady's veil is of white muslin, embroidered at the ends in gold and colours; that of a person of the lower class is simply dyed blue. In going abroad the ladies wear above their indoor dress a loose robe of coloured silk without sleeves, and nearly open at the sides, and above it a large enveloping piece of black silk, which is brought over the head, and gathered round the person by the arms and hands on each side. A face-veil entirely conceals the features, except the eyes; it is a long and narrow piece of thick white muslin, reaching to a little below the knees. The women of the lower orders have the same out-door dress of different materials and colour. Ladies use slippers of yellow morocco, and abroad, inner boots of the same material, above which they wear, in either case, thick shoes having only toes. The poor wear red shoes, very like those of the men.

Egypt.

Religion.

In religion the Muslim Egyptians are Sunnees, professing the creed which is commonly termed "orthodox," and are principally of the persuasion of the Shâfe'ees, whose celebrated founder, the Imâm Esh-Shâfe'ee, is buried in the great southern cemetery of Cairo. Many of them are, however, Hanafees (to which persuasion the Turks chiefly belong), and in parts of Lower, and almost universally in Upper, Egypt, Mâlikees. For the tenets of El-Islâm, the reader is referred to the article MAHOMMEDANISM.

Civil administration of justice.

The civil administration of justice is conducted in four principal courts of judicature; that of the Zâbit, or chief of the police, where trivial cases are summarily disposed of; the Deewân el-Khideewee, in the citadel, in which the pasha or his deputy presides, and where judgment is given in cases which either do not require to be referred to the two other courts yet to be mentioned, or which do not fall within their province; the Deewân el-Mahkemeh, the court of the kâdee, or chief judge, who is a Turk sent annually from Constantinople, and who must be a Hanafee; and that of the Muftee of the Hanafees, or chief doctor of the law, who decides all cases of difficulty. There are besides five minor mahkemehs or courts in Cairo, and one in each of the neighbouring towns of Boolâk and Masr El-'Ateekah, from which cases are always referred to the court of the kâdee; and each country town has a native kâdee, whose authority is generally sufficient for the villages around. The Council of the 'Ulama, or learned men, consists of the sheykh, or religious chief, of each of the four orthodox persuasions, the sheykh of the great mosque called the Azhar, who is of the persuasion of the Shâfe'ees, and is sometimes its sheykh, the kâdee, and the chief (Nakeeb) of the Shereefs, or descendants of the Prophet, with several other persons. This body was until lately very powerful, but now has little influence over the Pâshâ. Cairo is divided into quarters (Hârah, pl. Hârât), each of which has its sheykh, who preserves order among the people; and the whole city is partitioned into eight larger divisions, each having a sheykh called Sheykh et-Tumn. Various trades also have their sheykhs or chiefs, to whom reference is made in disputes respecting the craft; and the servants have similar heads who are responsible for their behaviour. The country is divided into governments, as before stated, each presided over by a Turkish officer, having the title of Mudeer, and sub-divided into districts under the control of native officers, bearing the title "Mamoor" and "Nâzir." A responsible person called Sheykh el-Beled (or "sheykh of the town," or "village"), presides over each small town and village, and is a native of the place. It must also be mentioned that the Sa'eed, or Upper Egypt, is governed by a pasha, whose residence is at Asyoot. Notwithstanding the consistent, able, and in many respects commendable, code of laws which has been founded on the Kur-ân and the Traditions, the administration of justice is lamentably faulty. As is the custom throughout the East, judgment in Egypt is usually swayed by bribes, and a poor man's case is generally hopeless when his adversary is rich. To this rule there have been some notable exceptions, and the memory of a few virtuous judges is cherished by the people, but such instances are very rare. The moral and civil laws observed by the Egyptians being those of El-Islâm will be found under another article.

Infancy, and early education.

It is very worthy of notice, that in Cairo, as in some other Muslim cities, any one may obtain gratuitously an elementary education, and he who desires the fullest attainable education may receive that also without the payment of a single fee, by joining a class of students in a collegiate mosque. The elementary instruction which most boys receive consists chiefly of reading, and learning the Kur-ân by

[1] *Modern Egyptians*, chap. i.

Egypt.

heart; day-schools, as charitable institutions, abound in Cairo, and every town possesses its school; a trifling fee to the fikee (or master) is the only expense incurred by the scholars. Girls are seldom taught anything beyond needle-work. The children of both sexes, except those of the wealthy, have generally a very dirty and slovenly appearance; and often intentional neglect is adopted to avert the effects of the "evil eye," of which the Egyptians entertain great dread. The children of the upper classes are excessively indulged, while the poor entirely neglect their offspring. The leading doctrines of El-Islâm, as well as hatred for all religions but their own, and a great reverence for their parents and the aged, are early inculcated. This deference towards parents cannot fail to strike every foreigner who visits Egypt, and does not cease with their growth; presenting an example well worthy of imitation in the west. Circumcision is observed at about the age of five or six years, when the boy is paraded, generally with a bridal procession, on a gaily caparisoned horse, and dressed in women's clothes. Some parents, however, and most of the learned, prefer a quieter and less expensive ceremony.[1]

Domestic life.

It is deemed disreputable for a young man not to marry when he has attained a sufficient age; there are therefore few unmarried men. Girls, in like manner, marry very young, some even at ten years of age, and few remain single beyond the age of sixteen; they are generally very prolific. The bridegroom never sees his future wife before the wedding night, an evil which is somewhat mitigated by the facility of divorce. A dowry is always given, and a marriage ceremony performed by a fikee (a schoolmaster, or one who recites the Kur-ân), in the presence of two witnesses; the ceremony is very simple, but constitutes a legal marriage. The bridal of a virgin is attended with great festivity and rejoicing; a grandee's wedding sometimes continuing eleven days and nights. On the last day, which should be that terminating with the eve of Friday, or of Monday, the bride is taken in procession to the bridegroom's house, accompanied by her female friends, and a band of musicians, jugglers, wrestlers, &c. As before stated, a boy about to be circumcised joins in such a procession; or, frequently, a succession of such boys. A Muslim is allowed by his religion four wives, but advantage is rarely taken of this license, and very few attempt to keep two wives in one house; the expense and discomfort which polygamy entails, act, therefore, as a restriction to its general adoption. A man may however possess any number of concubine slaves, who though objects of jealousy to the legal wife, are yet tolerated by her in consideration of her superior position, and conceded power over them, a power which she often uses with great tyranny: but certain privileges are possessed by the concubine, especially if she have born a son to her master. Such slaves are commonly kept only by grandees, the generality of the Muslim Egyptians being content with one wife. A divorce is rendered obligatory by the simple words, "Thou art divorced," and a triple divorce is irrevocable under ordinary circumstances. The hareem system of appointing separate apartments to the women, and secluding them from the gaze of men, is observed in Egypt as in other Muslim countries, but less strictly. Mr Lane says on this subject—"I believe that in Egypt the women are generally under less restraint than in any other country of the Turkish Empire; so that it is not uncommon to see females of the lower orders flirting and jesting with men in public, and men laying their hands upon them very freely. Still it might be imagined, that the women of the higher and middle classes feel themselves severely oppressed, and are much discontented with the state of seclusion to which they are subjected; but this is not commonly the case; on the contrary, an Egyptian wife who is attached to her husband is apt to think, if he allow her unusual liberty, that he neglects her, and does not sufficiently love her; and to envy those wives who are kept and watched with greater strictness."[2] The females of an Egyptian household never sit in the presence of the master, but attend him at his meals, and are treated in every respect as inferiors. The mother, however, forms a remarkable exception to this rule; in rare instances, also, a wife becomes a companion to her husband. On the other hand, if a pair of women's shoes are placed outside the door of the hareem apartments, they are understood to signify that female visitors are within, and a man is sometimes thus excluded from the upper portion of his own house for many days. Ladies of the upper or middle classes lead a life of extreme inactivity, spending their time at the bath, which is the general place of gossip, or in receiving visits, embroidering, and the like, and in absolute *dolce far niente*. It is therefore no cause for wonder that their tone of morals is generally low. Both sexes are abstemious in their food, though fond of pastry, sweetmeats, and fruit. The principal meals are breakfast, about an hour after sunrise; dinner, or the mid-day meal, at noon; and supper, which is the chief meal of the day, a little after sunset. Coffee is taken at all hours, and is, with a pipe, presented at least once to each guest. Tobacco is the great luxury of the men of all classes in Egypt, who begin and end the day with it, and generally smoke all day with little intermission. Many women, also, especially among the rich, adopt the habit. Men who can afford to keep a horse, mule, or ass, are very seldom seen to walk, and numberless excellent asses are to be hired in Cairo. Ladies always ride asses and sit astride. The poorer classes are of course unable to observe the hareem system, but the women are in general carefully veiled. Some of them keep small shops, and all fetch water, make fuel, and cook for their households. The food of the poor is very meagre; flesh meat is rarely tasted by them, and (besides bread), dates, raw cucumbers, and onions, are their common food, with soaked beans, roasted ears of Indian corn, &c.

Character, &c.

In their social intercourse the Muslim Egyptians are regular, and observe many forms of salutation and much etiquette; yet they are very affable, entering into conversation with strangers at shops and elsewhere. Their courtesy and dignity of manner are very striking, and are combined with ease, and a fluency of discourse. Of their mental qualifications Mr Lane remarks—"The natural or innate character of the modern Egyptians is altered, in a remarkable, degree, by their religion, laws, and government, as well as by the climate and other causes; and to form a just opinion of it is, therefore, very difficult. We may, however, confidently state that they are endowed, in a higher degree than most other people, with some of the more important mental qualities, particularly quickness of apprehension, a ready wit, and a retentive memory. In youth they generally possess these and other intellectual powers; but the causes above alluded to gradually lessen their mental energy."[3] Their principal virtues are piety and strong religious feeling, a strict observance of the injunctions of El-Islâm, and a constant sense of God's presence and overruling providence, combined however with religious pride and hypocrisy. Their common discourse is full of asseverations and expressions respecting sacred things, often however used with a levity which it is difficult for a person unacquainted with their feelings easily to reconcile with their respect for God. They entertain an excessive reverence for their Prophet; and the Kur-ân is treated with the utmost respect—never, for example, being placed in a low situation—and this is the case with everything they esteem holy. They are fatalists, and bear calamities with perfect resignation to the Divine will. Their filial piety and respect for the

[1] *Modern Egyptians*, chap. xxvii. [2] *Id.*, vi. [3] *Id.*, xiii.

Egypt.

aged have been before mentioned, and benevolence and charity are conspicuous in their character; poverty is therefore not accompanied by the distressing circumstances which too frequently attend it in Europe. Humanity to dumb animals is another virtue, and cruelty is openly discountenanced in their streets, even to unclean animals; this is however unfortunately wearing off in consequence of their intercourse with Franks. Their affability, cheerfulness, and hospitality, are remarkable, as well as frugality and temperance in food and drink, scrupulous cleanliness, a love of country, and honesty in the payment of debt. It should be added, however, that the Egyptians rarely, if ever, exercise their social virtues but towards persons of their own persuasion and country. Their vices are indolence, obstinacy, and libidinousness, especially among the women, cupidity (mitigated by generosity), envy, a disregard for the truth, and a habit of cursing. Murders, and other grave crimes of this nature, are rarely committed, but petty thefts are very common.

Language. "The Arabic spoken by the middle and higher classes in Cairo is," on the unquestionable authority of the *Modern Egyptians*, "generally inferior, in point of grammatical correctness and pronunciation, to the dialects of the Bedawees of Arabia, and of the inhabitants of the towns in their immediate vicinity, but much to be preferred to those of Syria, and still more to those of the Western Arabs."[1] The language varies in Upper and Lower Egypt, and is more correct inland than near the shores of the Mediterranean.

Literature. In the decay of Arab literature, Cairo still holds the chief place as a seat of learning, and its University, the Azhar, is undoubtedly the first of the Eastern world. Its professors teach "grammatical inflexion and syntax, rhetoric, versification, logic, theology, the exposition of the Kur-ân, the Traditions of the Prophet, the complete science of jurisprudence, or rather of religious, moral, civil, and criminal law, which is chiefly founded on the Kur-ân and the Traditions, together with arithmetic as far as it is useful in matters of law. Lectures are also given on algebra, and on the calculations of the Mohammedan calendar, the times of prayer, &c."[2] The students, as already remarked, pay no fees, and the professors receive no salaries. The latter maintain themselves by private teaching, and by copying manuscripts, and the former in the same manner, or by reciting the Kur-ân. The number of students may be, on an average, from 1500 to 2000. Except the professors of literature, few Egyptians are taught more than to read and write; and of these, still fewer can read and write well. The women, as before mentioned, are very rarely taught even to read.

Science. Science is but little studied, and barbers generally practise medicine and surgery. Mohammad 'Alee endeavoured to improve this state of things, by sending young men to Europe for the purpose of scientific study, and by establishing various schools, with the same object, in Egypt. His improvements were discouraged by Abbâs Pâshâ, who, happily for the country, is not now living; and we may hope that Sa'eed Páshâ may follow the example of his father, Mohammad 'Alee.

Saints. In common with other Muslims, those of Egypt have very many superstitions, some of which are peculiar to themselves. Tombs of saints abound, one or more being found in every town and village; and no traveller up the Nile can fail to remark how every prominent mountain has the sepulchre of its patron saint. The great saints of Egypt are the Imâm Esh-Shâfe'ee, founder of the persuasion called after him, the seyyid Ahmad El-Bedawee, and the seyyid Ibrâheem Ed-Dasookee, both of whom were founders of orders of Darweeshees. The former of these two is buried at the town of Tanta, in the Delta, and his tomb attracts many thousands of visitors annually to his principal festival: the latter is also much revered, and his festival draws together, in like manner, great crowds to his birthplace, the town of Ed-Dasook. But, besides the graves of her native saints, Egypt boasts of those of several members of the Prophet's family; the tomb of the seyyideh Zeyneb, daughter of 'Alee, that of the seyyideh Sekeeneh, daughter of El-Hoseyn, and that of the seyyideh Nefeeseh, great-grand-daughter of El-Hasan, all of which are held in high veneration. The mosque of the Hasaneyn (or that of the "two Hasans") is the most reverenced shrine in the country, and is believed to contain the head of El-Hoseyn. As connected with the superstitious practices of Egypt, Darweeshees must be mentioned, of whom there are many orders found in that country, the following being the most celebrated:—1. The Rifâ'eeyeh, and their sects the 'Ilwâneeyeh, and Saadeeyeh. 2. The Kâdireeyeh. 3. The Ahmedeeyeh, or followers of the seyyid Ahmad El-Bedawee, and their sects the Beiyoomeeyeh, Shaarâweeyeh, Shinnâweeyeh, and many others. 4. The Barâhimeh, or followers of the seyyid Ibrâheem Ed-Dasookee. These are all presided over by a direct descendant of the Khaleefeh Aboo-Bekr, called the Sheykh El-Bekree. The Saadeeyeh are the most famous for charming and eating live serpents, &c., and the 'Ilwâneeyeh for eating fire, glass, &c.

Darweeshees.

Charms. The Egyptians firmly believe in the efficacy of charms, a belief which is associated with that in an omnipresent and overruling Providence. Thus, the doors of houses are inscribed with sentences from the Kur-ân, or the like, to preserve from the evil eye, or avert the dangers of an unlucky threshold; similar inscriptions may be observed over most shops, while almost every one carries some charm about his person. Among so superstitious a people, with whom, as we have already seen, science is in a very low state, it is not to be wondered that the so-called sciences of magic, astrology in the place of astronomy, and alchemy in that of chemistry, are in a comparatively flourishing condition.[3]

The arts; industry. Since the time of the Turkish Conquest, the arts in Egypt have rapidly fallen into decay; this is partly attributable to the deportation of most of the skilled artificers of Cairo to Constantinople by the Sultân Seleem, but it is mainly owing to the misrule of the Turkish pâshâs, who have successively domineered over this unfortunate country. Cairo contains the most splendid specimens of Arab architecture of any part of the Arabian empire; but at present new buildings are erected after the Constantinopolitan model, or, what is still worse, the purely European—both styles immeasurably inferior to the Arab, and very ill suited to the requirements of the climate. In like manner, every other kind of native art is gradually perishing; and it is to be feared that even should the people be relieved from oppression and bad government, their industry will be encouraged rather to adopt imaginary improvements imported from Europe, than to cultivate the beautiful taste of their ancestors. The manufactures of the present inhabitants of Egypt are generally inferior to those of other eastern nations: their handicrafts are clumsy, and the inevitable results of tyranny are everywhere evident; nevertheless, the curious shops, the markets of different trades (the shops of each trade being generally congregated in one street or district), the easy merchant sitting before his shop, the musical and quaint street cries of the picturesque venders of fruit, sherbet, water, &c., with the ever-changing and many-coloured throng of passengers, all render the streets of Cairo a delightful study for the lover of Arab life, nowhere else to be seen in such perfection, or with so fine a back-ground of magnificent buildings.

[2] *Id.*, *ibid.*

[3] For very interesting details on the subject of Eastern magic, with its kindred sciences, the reader should consult the *Modern Egyptians*, and Lane's *Thousand and One Nights*, Knight, London, 1839, vol. i. chap. i., *note* 15.

Egypt. Luxuries, games, music.

Among the luxurious habits of the Egyptians must be classed the immoderate use of tobacco (as before mentioned), and coffee. They are, however, rarely guilty of the vice of drunkenness, wine being prohibited by the Kur-ân. Eaters of opium, and smokers of hemp, called hasheesh, are not uncommon, though they are always of the dregs of the people. The bath is a favourite resort of both sexes and all classes. In Cairo alone are upwards of sixty public baths, and every good house has a private bath. Their amusements are generally not of a violent kind, being rather in keeping with their sedentary habits, and the heat of the climate. They are acquainted with chess, draughts, backgammon, and other games, among which is one peculiar to themselves, called Mankalah, and played with cowries. The game of the gereed requires great bodily exertion; and wrestlers, &c., are found in the country, though not in any number. Music is the most favourite recreation of the people of Egypt; the songs of the boatmen, the religious chants, and the cries in the streets, are all musical. There are male and female musical performers; the former are both instrumental and vocal, the latter (called 'Almeh, pl. 'Awâlim) generally vocal. The 'Awâlim are, as their name ("learned") implies, generally accomplished women, and should not be confounded with the Ghawâzee, or dancing-girls. There are many kinds of musical instruments. The music, vocal and instrumental, is generally of little compass, and in the minor key; it is therefore plaintive, and strikes a European ear as somewhat monotonous, though often possessing a simple beauty, and the charm of antiquity, for there is little doubt that favourite airs have been handed down from remote ages. The prophet Mohammad condemned music, and its professors are in consequence lightly esteemed by the generality of Muslims, who nevertheless scruple not to enjoy their performances, and resort to the coffee-shops and to private festivities, where they are almost always to be found.

Dancing girls.

The Ghawâzee (sing. Ghâzeeyeh) form a separate class, very similar to the gypsies. They always intermarry among themselves only, and are all brought up to the venal profession. Their performances are too well known to need a description here, but it should be observed that the religious and learned Egyptians hold them to be improper. They dance in public, at fairs and religious festivals, and at private festivities, but not in respectable houses, whether before the men or the ladies. Mohammad 'Alee banished them to Isnè, in Upper Egypt; and the few that remained, occasionally dancing in Cairo, called themselves 'Awâlim, to avoid punishment. A most objectionable class of male dancers also exists, who imitate the dances of the Ghawâzee, and dress in a kind of nondescript female attire. Not the least curious of the public performances are those of the serpent-charmers, who are generally Rifâ'ee, or Saadee Darweeshes. Their power over serpents has been doubted by most European travellers, yet their performances remain unexplained; and apparently they possess means of ascertaining the haunts of these and other reptiles, and of alluring them forth; they, however, always extract the fangs of venomous serpents. Jugglers, rope-dancers, and farce-players, must also be mentioned. In the principal coffee-shops of Cairo are to be found reciters of romances, surrounded by interested audiences. They are of three classes, and recite from several works, among which was included, until lately, the *Thousand and One Nights;* but manuscripts of the latter have recently become so rare, as to render it almost impossible to obtain a copy.

Periodical public festivals.

The periodical public festivals are exceedingly interesting, and many of the remarkable observances with which they abound are passing away; but, happily, the *Modern Egyptians* contains the descriptions of its learned and minutely accurate author, an eye-witness of what he relates. The first ten days of the Mohammadan year are held to be blessed, and especially the tenth; and many curious and superstitious practices are observed on these days, particularly by the women. The tenth day, being the anniversary of the martyrdom of El-Hoseyn, the mosque of the Hasaneyn is thronged to excess, mostly by women. Following the order of the lunar year, the next festival is that of the Return of the Pilgrims, which is the occasion of great rejoicing, many having friends or relatives in the caravan. The Mahmal,[1] a kind of covered litter, first originated by the celebrated Queen, Sheger-ed-Durr, is brought into the city in procession, though not with as much pomp as when it leaves with the pilgrims. These and other processions have lost much of their effect since the extinction of the Memlooks, and the gradual disuse of gorgeous dress for the retainers of the officers of state. A regiment of regular infantry makes but a sorry substitute for the splendid cavalcade of former times. The Birth of the Prophet (Moolid en-Nebee), which is celebrated in the beginning of the third month, is the greatest festival of the whole year. During nine days and nights its religious ceremonies are observed at Cairo, in the open space called the Ezbekeeyeh. Next in time, and also in importance, is the Moolid El-Hasaneyn, commemorative of the birth of El-Hoseyn, and lasting fifteen days and nights; and at the same time is kept the Moolid of Es-Sâlih Eiyoob, the last king but one of the Eiyoobee Dynasty. In the seventh month occur the Moolid of the Seyyideh Zeyneb, and the commemoration of the Mearâg, or the Prophet's miraculous journey to heaven. Early in the tenth month (Shaabân), the Moolid of the Imâm Esh-Shâfe'ee is observed; and the night of the middle of that month has its peculiar customs, being held by the Muslims to be that on which the fate of all living is decided for the ensuing year. Then follows Ramadân, the month of abstinence, a severe trial to the faithful; and the Lesser Festival (El-'Eed es-Sagheer), which commences Showwâl, is hailed by them with delight. A few days after, the Kisweh, or new covering for the Kaabeh at Mekkeh, is taken in procession from the citadel, where it is always manufactured, to the Mosque of the Hasaneyn to be completed; and, later, the caravan of pilgrims departs, when the grand procession of the Mahmal takes place. On the tenth day of the last month of the year, the Great Festival (El-'Eed el-Kebeer), or that of the Sacrifice, closes the calendar.

Observances connected with the rise of the Nile.

The rise of the Nile is naturally the occasion of annual customs, some of which are doubtless relics of antiquity: these are observed according to the Coptic year.[2] The commencement of the rise is fixed to the night of the eleventh of Ba-ooneh (Paôni), the seventeenth of June, and is called that of the Drop (Leylet en-Nuktah), because a miraculous drop is then supposed to fall, and cause the swelling of the river. The real rise commences at Cairo about the summer solstice, or a few days later; and on about the third of July a crier in each district of the city begins to go his daily rounds, announcing, in a quaint chant, the increase of water in the Nilometer of the island of Er-Rôdah. When the river has risen twenty or twenty-one feet, he proclaims the Wefà en-Neel, "Completion" or "Abundance of the Nile." On the following day, the dam which closes the canal of Cairo is cut with much ceremony, and

[1] Mahmil is probably the correct pronunciation of this word.

[2] With reference to this curious fact, and also in connection with the subject, it may here be mentioned that the period of the hot winds, called the Khamâseen, that is "The Fifties," is calculated from the day after the Coptic Easter, and terminates on the day of Pentecost, and that the Muslims observe the Wednesday preceding this period, called "Job's Wednesday," as well as its first day, when many go into the country from Cairo "to smell the air." This day is hence called Shemm en-Neseem, or "the smelling of the zephyr." The 'Ulama observe the same custom on the first three days of the spring quarter.

this is the signal for letting the inundation over the surface of the country. A pillar of earth before the dam is called the "Bride of the Nile," and Arab historians relate that this was substituted, at the Muslim conquest, for a virgin whom it was the custom annually to sacrifice, to ensure a plentiful inundation. A large boat, gaily decked out, representing that in which the victim used to be conveyed, is anchored near, and a gun on board is fired every quarter of an hour during the night. Rockets and other fireworks are also let off, but the best, strangely, after daybreak. The Governor of Cairo attends the ceremony of cutting the dam, with the Kádee and others. The crier continues his daily rounds, with his former chant, excepting on the Coptic New-Year's Day, when the cry of the Wefà is repeated, until the Saleeb, or Discovery of the Cross, the 26th or 27th of September, at which period, the river having about attained its greatest height, he concludes his annual employment with another chant, and presents to each house some limes and other fruit, and dry lumps of Nile mud.

Funeral rites.

This brief account of the modern Egyptians would be incomplete without a few words concerning the rites attendant on death. The corpse is immediately turned towards Mekkeh, and the females of the household, assisted by hired mourners, commence their peculiar wailing, while fikees recite portions of the Kur-ân. The funeral takes place on the day of the death, if that happen in the morning; otherwise on the next day. The corpse, having been washed and shrouded, is placed in an open bier, covered with a Cashmere shawl, in the case of a man; or in a closed bier, having a post in front, on which are placed female ornaments, in that of a woman or child. The funeral procession is headed by men called "Yemeneeyeh," chanting the profession of the faith, followed by male friends of the deceased, and a party of schoolboys, also chanting, generally from a poem descriptive of the latter state. Then follows the bier, borne on the shoulders of friends, who are relieved by the passers-by, such an act being deemed highly meritorious. On the way to the cemetery the corpse is generally, in Cairo, in the case of the northern quarters of the city, carried either to the Hasaneyn, or, if the deceased be one of the 'Ulama, to the Azhar; or, in the case of the southern quarters, to the seyyideh Zeyneb, or some other revered mosque. Here the funeral service is performed by the Imám, or minister of the mosque, and the procession then proceeds to the tomb. In the burials of the rich, water and bread are distributed to the poor at the grave, and sometimes a buffalo or several buffaloes slaughtered there, and the flesh given away. The tomb is always a vault, surrounded by an oblong stone monument, with a stela at the head and feet, and a cupola, supported by four walls, covers the whole in the case of sheykhs' tombs and those of the wealthy. During the night following the interment, called the Night of Desolation, or that of Solitude, the soul being believed to remain with the body that one night, fikees are engaged at the house of the deceased to recite various portions of the Kur-ân, and, commonly, to repeat the first clause of the profession of the faith, "There is no deity but God," three thousand times. The women alone put on mourning attire, by dyeing their veils, shirts, &c., dark blue, with indigo; and they stain their hands, and smear the walls, with the same colour. Everything in the house is also turned upside down. The latter customs are not, however, observed on the death of an old man. At certain periods after the burial, a khatmeh, or recitation of the whole of the Kur-ân, is performed, and the tomb is visited by the female relations and friends of the deceased. The women of the Felláheen (or peasants) of Upper Egypt observe some strange dances, &c., at funerals, which must be regarded as partly relics of ancient Egyptian customs.

For the fullest information on the subjects of the foregoing sketch, the reader is referred to Lane's *Modern Egyptians*, to its author's translation of the *Thousand and One Nights*, and, in particular, to the notes appended to that translation; and to the *Englishwoman in Egypt*, by Mrs Poole.

Copts.

The native Christians of Egypt, or Copts, are chiefly descended from the ancient Egyptian race; and as they rarely intermarry, they preserve in their countenances a great resemblance to the representations of the tombs and temples. Their dress and customs are very similar to those of the Muslim Egyptians, but their reserve towards persons of another persuasion renders a knowledge of their peculiar observances exceedingly difficult. The causes which produced the separation of their Church will be noticed in the historical portion of this article; and in the same part will be found mention of the chief persecutions which they have suffered. Under Mohammad 'Alee they were relieved of much oppression, and the immunities then granted to them they still enjoy. The neglected appearance of their houses, and their want of personal cleanliness, is in strong contrast to the opposite habits of the Muslims, and European residents generally prefer the latter as domestic servants.

Jews.

The Jews of Egypt, of whom there have been great numbers since the captivity of the Ten Tribes, appear to be even more degraded than their fellows in other countries. They are held in the utmost abhorrence by the dominant race, and often are treated with much cruelty and oppression. Many are bankers and money-changers, &c. The quarter of the Jews in Cairo is exceedingly filthy, and would give a stranger the notion that they labour under great poverty. But such is not the case; the fear of the Muslims inducing them to adopt this outward show of misery, while the interior of many of their houses is very handsome and luxurious.

SECTION II.

CHRONOLOGY AND HISTORY.

Chronology.

It is not possible, within the limits of the present article, even to enumerate the various opinions which have prevailed respecting the chronology of ancient Egypt, strictly speaking, and respecting the chronological results deduced from different arrangements of its dynasties. On the former subject it will suffice to mention the divisions of time, particularizing those which are generally received, as to their characteristics, or as to their periods of commencement also; and on the latter, to state the main differences between the views of the learned.

Seasons.

The Egyptians, from very early times, subdivided the year which they commonly used into three seasons, each containing four months, called the first, second, third, and fourth months of these seasons. This notation obtained from a very remote period,[1] probably dating as far back as near the commencement of Egyptian history. The three seasons were called "the season of Vegetation," "the season of Manifestation," and "the season of the Waters," or "the Inundation."[2] The interpretation of the names of the first two seasons is doubtful, but that of the third is certain, and enables us to ascertain the characteristics of the year to which these names of the seasons must have originally applied.

Tropical Year.

The fitness of the division is shown by our finding it universally used in Egypt in the present day, though vaguely defined; the three seasons being called الشِّتَاء "Winter," الصَّيْف "Summer," and النِّيل "the Inundation," literally "the Nile," meaning the season at which the Nile is spread over the cultivable parts of Egypt. The season of the waters can be shown to have commenced a month before the autumnal equinox, and to have terminated

[1] Lepsius, *Chronologie der Aegypter*, i., p. 148.

[2] *Horæ Æg.*, pl. i., No. 1.

at the winter solstice, at which period, therefore, the Tropical Year commenced, when all things in Egypt begin anew. At what time the Tropical Year was instituted has not been ascertained, but it must have been at least as ancient as the nomenclature of the months, which, as above mentioned, was in use in very early times; and when it came to be disused is likewise uncertain.[1] That the Egyptians possessed a Tropical Year is generally admitted, but its time of commencement has been matter of doubt and difference.

Vague Year.

The Egyptians had also, in ancient times, a year consisting of 365 days, apparently older than the Tropical Year, and consecrated by its antiquity. This year is commonly called the "Vague Year," and was subdivided into twelve months of thirty days each, with an addition of five Epagomenæ, or intercalary days, after the twelfth month. It was divided into the three seasons of the Tropical Year, and the months were called after those seasons. It was in common use at least as early as the time of the second king of the Eighteenth Dynasty[2] (about B.C. 1500), and was not abandoned until it was made a Julian Year by Augustus, B.C. 24. No diversity of opinion prevails respecting the Vague Year.

Sothic Year.

Another year was used by the ancient Egyptians, but, apparently, only for astronomical and possibly for religious purposes, for both of which the Vague Year was also employed. It was the Sothic Year, commencing on the 20th of July, the day of the so-called heliacal rising of Sothis.[3] There is a calendar sculptured on the exterior of the great temple of Medeenet-Haboo at Thebes, which may be that of a Sothic Year; and if so, this year would have been in use as early as about B.C. 1200; but this cannot be considered certain.[4] It seems most probable that the Sothic Year was only a year of the priests, which originated not long before, or subsequently to, the commencement of the first Sothic Cycle, B.C. 1322, and it does not seem unreasonable to conjecture that it was instituted with the cycle.[5] Its length was 365¼ days, so that it differed from the Julian alone in the time of its commencement. There is no disagreement among scholars respecting it.

Egyptian Julian Year.

When Egypt had become a province of the Roman empire, Augustus commanded the inhabitants to make use of a Julian Year in their public records. But instead of fixing its commencement to be that of the common Julian year, the Egyptians made the Vague Year Julian by intercalation; consequently the Egyptian Julian Year always began on the 29th, or, in the year next after their leap-year, the 30th, of August, O.S., which was the day on which the Vague Year commenced B.C. 24, when the new reckoning was instituted. The Copts and the Egyptian peasants still make use of this year.[6]

Names of months.

The names by which the Egyptian months were called (excepting in hieroglyphic inscriptions) in the times of the Ptolemies and Cæsars—Thôth or Thôÿth, Paôphi, &c.—are never found, as such, in hieroglyphics of any time. They were chiefly or wholly derived from the names of the divinities to which the months were held to be sacred.[7] These names were, in the Memphitic dialect of Coptic, if we adopt the most probable reading assisted by the manner in which they have been written in Greek, as follows: 1, Thôüt; 2, Paôpi; 3, Athôr; 4, Choiak; 5, Tôbi; 6, Mechir; 7, Phamenôth; 8, Pharmuthi; 9, Pachôn (or rather Pachôns, as the name in the Sahidic dialect is Pashons or Pashôns, and in Arabic, Beshens, and its etymology supports this correction); 10, Paôni; 11, Epêpi; 12, Mesôrê. The Arabic names are merely corrupt forms of these.[8]

Day.

The day among the ancient Egyptians commenced in the morning six hours before noon,[9] and was equally divided into day and night, each of which contained twelve hours, numbered from one to twelve, as is shown by the astronomical tables in the tombs of the kings at Thebes[10] (about B.C. 1200). The hour is also mentioned in earlier inscriptions. It was subdivided into smaller periods, of which the length has not been ascertained with certainty.[11]

Hour.

Cycles.

Ancient writers speak of various cycles in use among the Egyptians, and the monuments mention great periods of time. It has been argued that the coincidence of the Vague Year and the Tropical was probably the commencement of a cycle; and it is known that a cycle began when Sothis rose heliacally on the first of Thôth, or, if the Sothic Year had been already instituted, when that year coincided with the Vague.

Tropical Cycle.

The Tropical Cycle claims the first notice. Such a cycle, comprehending the period during which the Vague Year passed through all the seasons of the Tropical, would properly exceed by a few years fifteen centuries of Vague Years, but, if also lunisolar, would consist of exactly fifteen hundred Vague Years; and we may fairly suppose that to have been its length, because the Egyptians could scarcely have arrived at a more accurate determination, and because they are stated to have used periods of five hundred years, a third of that sum. Admitting that such would have been the length of an ancient Egyptian Tropical Cycle, we must inquire, in the next place, when it would have commenced. The most natural period of its commencement would be the coincidence of the Tropical and Vague Years, and of the years in which this coincidence might be considered by the ancient Egyptians to take place, that would be chosen in which there was a new moon on the first day of Thôth. But if we consult the monuments, we find that the vernal equinox was the most important of the tropical points, and the greater ease of its determination would give it a preference above the winter solstice. It is, therefore, not unreasonable to conclude that the beginning of the cycle was marked by the coincidence of the Tropical and Vague Years, and the occurrence of a new moon on the day of the vernal equinox. At a period which the chronology of the dynasties, apart from all astronomical considerations, shows to have been by no means distant from that of the coincidence of the Vague and Tropical Years, we find the record of the commencement of some unknown period, apparently connected with the vernal equinox; and again, fifteen hundred years later, we observe another though less distinct record of the same nature. Hence, if it be admitted that the year with which the Tropical Cycle began was one in which a new moon fell on or very near the day of the vernal equinox, we may compute the commencements of two of these cycles,—as, January 7, B.C. 2005, in the reign of Amenemha II., the second king of the Twelfth Dynasty, and December 28 B.C. 507, when Egypt was a Persian province, under Darius Hystaspis.[12]

Sothic Cycle.

The Sothic Cycle is one respecting which chronologers are agreed. It was a period of 1460 Sothic or Julian, and 1461 Vague Years, and its commencement was marked by a so-called heliacal rising of Sothis, or Sirius,[13] on the first day of the Vague Year, which could only recur at the return of the cycle, according to the Egyptian calculation. One of these cycles commenced July 20, B.C. 1322, most pro-

Egypt.

bably during the reign of Sethee I., the head of the Nineteenth Dynasty;[1] and the next, on the same day A.D. 138, in the reign of Antoninus Pius. The only matter of argument respecting these periods is, whether there were any before that commencing B.C. 1322. There is no distinct evidence to show that such was the case, but, on the contrary, there is presumptive evidence that the period was instituted in that year.[2]

Phœnix Cycle.

The Phœnix Cycle is a very important period in Egyptian chronology, but one respecting which the statements of ancient writers, as well as the opinions of modern scholars, have presented a remarkable diversity. An examination of the Egyptian monuments, however, indicates the length of the true Phœnix Cycle, and the dates of its commencements. In the celebrated astronomical ceiling of the Rameseum of El-Kurneh, commonly, but incorrectly, called the Memnonium, we find a representation of a constellation bearing the name Ben-nu Osir, or the Phœnix of Osiris, and having the form of a kind of heron. It is placed under the sixth month, indicating that it rose heliacally, in the Egyptian acceptation of the term, during that month, when Sothis so rose on the first of Thôth, or during that month. As no precise day is fixed as that of the rising of the Phœnix, we cannot determine to what constellation it corresponded, but it most probably represents Cygnus, the "Bird" (Ὄρνις) of the Greeks, and perhaps it also partly included Aquila, or comprehended part of each of those constellations. Ancient writers speak of the appearance of the Phœnix on various occasions: this must allude to the heliacal rising of the constellation, that is, of its principal, or of its last star; for the ancient Egyptian expression for heliacal rising, meaning thereby the rising of a star about one hour before sunrise, is "manifestation," or "appearance." Reasoning, therefore, from analogy, the Phœnix Cycle would commence when the Phœnix rose about an hour before the sun on the first day of the Vague Year, and consist, like the Sothic Cycle, of 1460 Julian years, and 1461 Vague. Supposing this to have been its duration, the position of the Phœnix in the ceiling of the Rameseum of El-Kurneh would enable us to fix approximatively the commencement of a Phœnix Cycle preceding the date of that sculpture, to some one of the years B.C. 2042 to 1923 inclusive. This view of the Phœnix Cycle is strengthened by a remarkable passage of Tacitus, wherein he says that some assigned a length of 1461 years as the interval between appearances of the Phœnix, and stated that they occurred first in the reign of Sesostris, then in that of Amasis, and then in that of Ptolemy, "the third Macedonian sovereign."[3] Now, the reign of Amasis falls within the approximative date of the commencement of the Phœnix Cycle following that already calculated from the ceiling of the Rameseum. The duration of that reign was B.C. 570 to 525 inclusive;[4] whence we may calculate the limits of the commencement of the preceding cycle, supposing the length to be 1460 years, as B.C. 2030 to 1985 inclusive, the approximative date being thus narrowed. But the means of accurately fixing these dates appears to be afforded by the Calendar of the Panegyries, for it has been argued with much probability, that the Egyptians had great Panegyrical periods, whereof four composed a sum of 1461 Julian years, and that two of these periods commenced respectively Jan. 2 B.C. 1986, which will agree with the reign of the old Sesôstris, Sesertesen III., and Jan. 2 B.C. 525 during that of Amasis. These, therefore, would be likewise commencements of the Phœnix Cycle, the duration of which would be 1461 Julian Years, and not 1460, which indeed may be the meaning of Tacitus. The appearance of the Phœnix in the time of Ptolemy, the third Macedonian sovereign, by whom Ptolemy Euergetes is intended, is clearly at variance with the statement respecting the length of the interval, if the appearance in the reign of Amasis be accepted, and there is every reason for giving the latter the preference.[5]

Egypt.

Panegyrical Periods.

On the monuments of ancient Egypt, mention is frequently made of various Panegyrical periods in particular, and of periods of Panegyries in general. Many opinions have prevailed respecting them, and the subject is one of so intricate a nature, that it cannot be investigated in the present article. It is intended rather, in the following observations, to present an outline of the only distinct and complete explanation of these divisions of time, giving references to where the reader will find a full investigation of them.

It is important to distinguish between the system of Panegyrical periods and the Royal Panegyries, of which somewhat will be said subsequently. The former consisted of a year, month, and division of a month. The year, or Great Panegyrical Year, had a mean length of 365¼ Julian years, having alternately a length of 364½ and 366 years. The Great Panegyrical Month, of which there were twelve to the year, contained thirty Julian years, and was divided into twenty Divisions of the Great Panegyrical Month, each having a length of one Julian year and a half. There must also have been an intercalation of four years and a half, or six years, after the twelfth Panegyrical Month. The commencement of the Tropical Cycle being dated as having occurred in the twelfth Division of the twelfth Great Panegyrical Month, enables us to ascertain the beginning of one Great Panegyrical Year, and consequently of the rest. The following are the dates of their commencements:—

First Great Panegyrical Year, B.C. 2717, Era of Mênês, the first king of Egypt. Length 364½ years.

Second Great Panegyrical Year, B.C. 2352, in the time of Sûphis I. and II., kings of the Fourth Dynasty. Length 366 years.

Third Great Panegyrical Year, and commencement of the first Phœnix Cycle, B.C. 1986, in the time of Sesertesen III., the fourth king of the Twelfth Dynasty. Length of the Great Panegyrical Year 364½ years.

Fourth Great Panegyrical Year, B.C. 1622. Length 366 years.

Fifth Great Panegyrical Year, B.C. 1256. Length 364½ years.

Sixth Great Panegyrical Year, B.C. 891. Length 366 years.

Seventh Great Panegyrical Year, and commencement of the Second Phœnix Cycle, B.C. 525, in the reign of Amasis. Length of Great Panegyrical Year, 364½ years.

Eighth Great Panegyrical Year, B.C. 161, in the reign of Ptolemy Philometor. Length 366 years.

Ninth Great Panegyrical Year, A.D., 205, in the reign of the Roman Emperor Septimius Severus.

The earliest mention upon the monuments of the Panegyrical periods of this class is found in the inscriptions commemorating the commencement of the Second Great Panegyrical Year, and the latest certain notice is probably of the time of Darius Hystaspis. The following are the dates recorded on the monuments, wherein these periods are used:—

2352 B.C.	Commencement of the Second Great Panegyrical Year. Time of Sûphis I. and II. Fourth Dynasty.
2005	Commencement of the First Tropical Cycle. Time of Amenemha II. Twelfth Dynasty.
1472-1	Date in fourth year of Skhee. Eighteenth Dynasty.

[3] Paullo Fabio L. Vitellio consulibus post longum seculorum ambitum, avis Phœnix in Ægyptum venit; præbuitque materiem doctissimis indigenarum, et Græcorum, multa super eo miraculo disserendi; de quibus congruunt, et plura ambigua, sed cognitu non absurda, promere libet. Sacrum soli id animal, et ore ac distinctu pinnarum à ceteris avibus diversum, consentiunt qui formam ejus definiere. De numero annorum varia traduntur. Maxime vulgatum, quingentorum spatium. Sunt qui adseverent, mille quadringentos sexaginta unum interjici; prioresque alites Sesostride primum, post Amaside dominantibus, dein Ptolemæo, qui ex Macedonibus tertius regnavit, in civitatem cui Heliopolis nomen, advolavisse, multo ceterarum volucrum comitatu, novam faciem mirantium. Sed antiquitas quidem obscura: inter Ptolemæum ac Tiberium minus ducenti quinquaginta anni fuerunt, unde nonnulli falsum hunc Phœnicem, neque Arabum è terris credidere, nihilque usurpavisse ex his quæ vetus memoria firmavit.—*Ann.* vi., 28.

[4] It is generally agreed that Amasis died in the year B.C. 525; and since the Phœnix Cycle commenced in January of that year, as is subsequently shown, it can hardly be doubted to have fallen in his reign.

[5] See *Horæ Æg.*, p. 39, and pl. ii.

Egypt.

1442 B.C. Date in sixteenth year of Queen Amen-numt. Eighteenth Dynasty.
1412 Date in thirty-third year of Thothmes III. Eighteenth Dynasty.
591 Date in reign of Psammetichus II. Twenty-sixth Dynasty.
561 Date in reign of Amasis. Twenty-sixth Dynasty.[1]

It is necessary to mention the Calendar of the Decans, which was connected with that of the Panegyries. The ancient Egyptians distinguished thirty-six stars or asterisms, nearly equidistant, throughout a great circle of the heavens (like the signs of the zodiac), which rose at intervals of about ten days. The two most important of the Decans were Sothis and Smat, which were distant half a year from one another.[2]

Royal Panegyries.

Besides the Panegyrical periods above mentioned, were those of the Royal Panegyries. These were thirty-year periods or Triacontaëterids, as they are called on the Rosetta Stone, and subdivisions, having apparently a length of three years. They were probably counted from the king's accession, and his first Triacontaëterid festival, celebrated at or about the completion of his thirtieth year. They seem to have been reckoned by Julian years, and celebrated at the first indication of the rise of the Nile.[3] Respecting the duration of the Triacontaëterids, there is of course a general agreement, since it rests upon indubitable authority.[4]

Arrangement of Dynasties.

Modern writers have generally depended upon an arrangement of the dynasties for the duration of ancient Egyptian history. Some have held those dynasties to have ruled consecutively; but others have maintained that many of them were contemporaneous. Hence have arisen two chronological systems, of which some account must here be given.

Those who hold the dynasties to have been all consecutive, assign to the Egyptian monarchy a duration of upwards of 5000 years. It is, however, generally admitted in the present day, that this is an extravagant period, and that both the writings of ancient historians, and the evidence of the monuments, lead to the conclusion that many of the earlier dynasties were contemporary. But here again there is a wide difference of opinion; some holding, that though the monuments afford general evidence of contemporaneousness—for example, by the progress of art—no distinct evidence has been yet obtained from them of the contemporaneousness of any two kings of different dynasties; while others maintain that the hieroglyphic inscriptions do afford such distinct evidence of contemporaneousness. Chevalier Bunsen and Professor Lepsius are the best scholars who have advanced the former view, and it is necessary therefore to give an outline of their method. They both recognise the absurdity of the opinion that the dynasties were all consecutive; but being unable to obtain monumental evidence as to the order of their contemporaneousness, and the obvious order, to be mentioned subsequently, not occurring to them, they were forced to look to ancient writers for some distinct statement of the duration of the Egyptian kingdoms as a whole. This wished-for sum they found in a passage of the Byzantine Syncellus, who states that, according to Manetho, the duration of the Thirty Dynasties, from Mênês the first king, to Nectanabo [II.] the last, was 3555 years. This sum they unhesitatingly accept, and rest their whole chronology upon it, having, for that part of it which is anterior to the sixteenth or seventeenth century B.C., and respecting which alone there are serious differences of opinion, absolutely no other reliable support.[5] It is important, therefore, to examine into the trustworthiness of a vessel which has carried these inquirers so far into the ocean of time.

In the first place, it must be remarked that a solitary number which is found in a single work of a single author is always to be regarded with caution, more especially when that author is as careless as Syncellus. It becomes, therefore, a hazardous matter to build a chronological arrangement upon this number. But the next inquiry should be, whence Syncellus derived the sum, since two persons have the name of Manetho without distinction in his writings—the true Manetho, the native historian of Egypt, and the false Manetho, usually called Pseudo-Manetho, who usurped the historian's name as a passport for his impostures. Besides Syncellus, four other writers, all preceding him in time, Africanus, Eusebius, Theophilus of Antioch, and the Jewish historian Josephus, quote from the true Manetho or refer to him. Syncellus does not appear to have had access to his work, and makes no distinction between him and the impostor, calling both Manetho. In every instance in which what he states on Manetho's authority is not found in the works of the four writers above mentioned, excepting that of the passage under consideration, it is admitted by all to have been derived from Pseudo-Manetho. External evidence therefore would induce an unprejudiced inquirer to ascribe the sum of 3555 rather to the false Manetho than to the true. Internal evidence increases this suspicion of the passage. Therein it is stated that the time was that of 113 generations in thirty dynasties. Now the Old Chronicle, an undoubted imposture, treated in like manner of the history of Egypt under thirty dynasties in 113 generations during a great and imaginary cycle. By this Old Chronicle, according to Syncellus's opinion, was Manetho, that is the Pseudo-Manetho, as Bunsen acknowledges, led astray.[6] The agreement in the sum of generations is most striking; that of the number of dynasties affords no argument, thirty being the true number. Hence an additional doubt is thrown upon this statement; and a careful comparison of its sum of years with what we may believe to be derived from the chronology of Pseudo-Manetho or his followers, does not tend to lessen our suspicion, although a positive proof cannot be thus obtained. In the order of the dynasties, Bunsen and Lepsius have admitted some of the earlier to have been contemporary, but in arranging them they have differed considerably. The main point of disagreement is with respect to the Shepherd dynasties, of which Bunsen makes a Middle Empire between the Old Empire and the New, as he terms them, supposing these dynasties to have ruled without any contemporary Egyptian line. This Lepsius opposes, holding the Shepherds never to have governed without contemporary Egyptians, and dividing the dynasties into the Old Empire and the New.

To Mr Lane archæology is indebted for the discovery of the true order of contemporaneousness of the dynasties. As long ago as the year 1830 he discovered that order from "the evidence given by Manetho and others, that some of the early dynasties were contemporary, and upon a consideration of the ordinal and other appellations (or numbers and names) by which those dynasties are distinguished [by Manetho]; for the interpretation of hieroglyphics was not then certain enough for him to obtain clear monumental evidence." An examination of the hieroglyphic inscriptions has proved Mr Lane's accuracy,[7] and the arrangement has received the high sanction of Sir Gardner Wilkinson.[8] The following table will explain the order of the contemporary dynasties, that is, the first seventeen: under the eighteenth dynasty Egypt was a single kingdom, and most, if not all, of the subsequent dynasties were successive. The dates of the commencement of each dynasty in the table are more or less approximative, as are also their durations; but the fixed dates show that neither can be far wrong in all the most important instances.

1 *Horæ Æg.*, pp. 61–68. The date of Thothmes III. is mentioned (p. 72–73) as of Royal Panegyries, but the author has since come to the conclusion that it is that of the commencement of a Great Panegyrical Month.

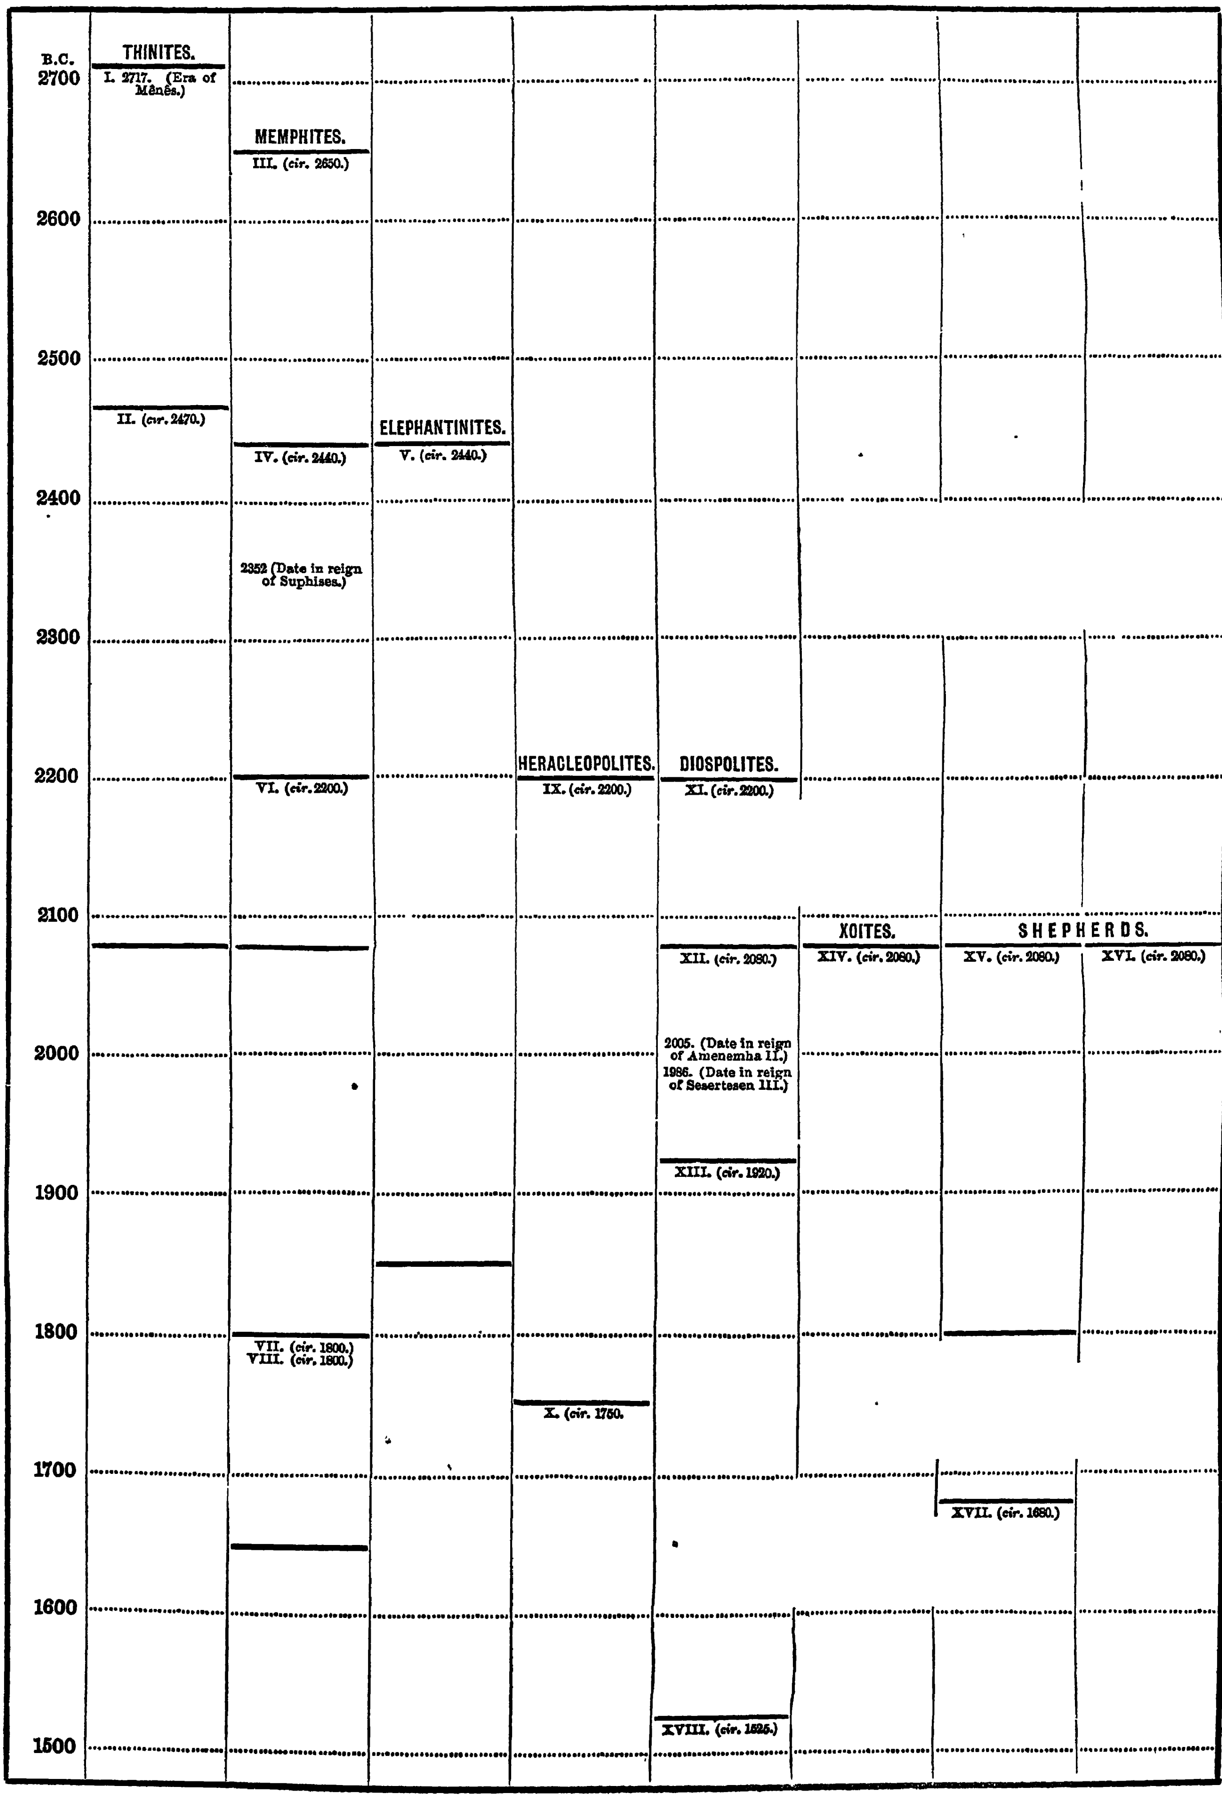
Egypt.

Table of the first seventeen dynasties.



Egypt.

Table of the first seventeen dynasties.

Egypt.

History.

Mênês, the head of the First Dynasty, is related to have been the first mortal king of Egypt.[1] Manetho states that the period before his reign was occupied by the rule of the gods, demigods or heroes, and manes, extending through nearly 25,000 years, according to Eusebius.[2] Similar statements are found in the writings of Herodotus and Diodorus.[3]

Divine Dynasties.

These divine dynasties, whether cyclical or not, have no place in history, being purely mythical and not traditionary. And it should be observed, that whereas in the annals of other ancient nations a time of tradition intervenes between that of myths and that of facts, no such period of transition is found in the Egyptian records, where we find pure fiction immediately followed by accurate history.

First Dynasty. Mênês, or Menee.

Hence it seems reasonable to suppose that at the time of Mênês, or not long before, Egypt was colonized from another country, and this is entirely in accordance with the most probable Septuagint date of the Dispersion about half a century before the Era of Mênês, B.C. 2717, which was probably the date of his accession.[4] Whether or not the Mizraite settlers may have found an aboriginal population is a question too large to be discussed in this brief historical notice.[5]

With Mênês, therefore, Egyptian history commences. His dynasty is stated to have been one of Thinite kings, of the city of This, situated near to Abydos in Upper Egypt.[6] Respecting Mênês, Manetho, according to Eusebius, relates that he made a foreign expedition and acquired renown; and, moreover, that he was killed by a hippopotamus, as Africanus also mentions.[7] Diodorus Siculus, who calls him Mênas, states that he first instructed the Egyptians in religion, and so changed their simple manners that Trephachthus, the father of Bocchoris the Wise, finding from experience the happiness of a frugal life, and the evils of luxury, inscribed a curse against him in the temple of Jupiter (or Amen-ra), at Thebes.[8] Herodotus says that Mênês founded the city of Memphis, after he had diverted the course of the river by raising a dyke. The same historian mentions that he built the temple of Hephæstus (or Ptah) in Memphis.[9] His name, written Menee, has been found in hieroglyphic characters in a sort of list, or procession of small statues of kings, in the Rameseum of El-Kurneh,[10] and in hieratic characters in the Royal Turin Papyrus.[11]

Athôthis.

Mênês was succeeded, after a long reign, by Athôthis his son, respecting whom Manetho tells us that he built the palace at Memphis, and that he was a physician, and left the anatomical books.[12] This, as well as what Herodotus relates of his father having changed the course of the river, however that be understood, shows that the Egyptians were at this remote period a highly civilized people; and the circumstances that, after an interval of less than four centuries from the accession of the first king, we find magnificent pyramids as royal sepulchres, and the tombs of the subjects sculptured and having hieroglyphic inscriptions, confirm this opinion. The Third Dynasty commenced, and Memphis became independent, during, or soon after, the reign of Athôthis; but as the exact time of this change is not determined, it will be best to notice the later Thinite kings before speaking of the Memphite line of sovereigns.

Uenephês.

Uenephês, the fourth Thinite king, is said by Manetho to have built the pyramids near Kôchômê, a place which has not been identified; and it is added that Egypt was afflicted by a famine in his reign.

Semempsês.

In the time of Semempsês, the seventh king, there was a very great plague.[13] With his successor the dynasty terminated, having ruled, in all probability, about two centuries and a half.

Second Dynasty.

The few particulars that we know of the history of the Second Dynasty, in which the Thinite line was continued, are related by Manetho alone. He says that in the reign of the first king Boêthos, a chasm of the earth opened at Bubastis, and many perished; that under the second king Kaiechôs, the bulls Apis in Memphis, and Mnevis in Heliopolis, and the Mendesian goat, were called gods, as already mentioned; and that under the next king Binôthris, it was adjudged that women could hold the sovereign power.

Kaiechôs. Binôthris.

Nepherchêrês.

During the reign of the seventh king Nepherchêrês, called Nufre-ka-ra in the hieroglyphical list known as the Tablet of Abydos,[14] Manetho tells us that it was fabled that the Nile flowed mixed with honey for the space of eleven days. His successor, according to the Egyptian historian, was Sesôchris, a man of gigantic stature.[15]

Sesôchris.

Nothing further is related by Manetho of the occurrences of this dynasty, to which he assigns a duration of about 300 years. From the monuments, however, it appears most probable that it lasted little less than four centuries, and that the Thinite kingdom came to a close with it at the time of the Shepherd invasion.

Third Dynasty. Necherôphês.

The Memphite kingdom, as already noticed, commenced not long after the Thinite, with the Third Dynasty. Manetho relates that during the reign of its first king Necherôphês or Necherôchis, the Libyans revolted from the Egyptians, but returned to their allegiance, being terrified by a sudden increase of the moon.

Tosorthros.

The second Memphite sovereign Tosorthros, or Sesorthos, is said by the same authority to have been called by the Egyptians Æsculapius, on account of his medical knowledge, and to have invented the art of building with hewn stones, and to have patronized literature.[16] After having lasted about two centuries, this dynasty was succeeded by the Fourth, one of the most famous of the lines which ruled in Egypt, while the Fifth Dynasty of Elephantinite kings arose at the same time.

Fourth Dynasty. Sôris, or Shura.

Of Sôris, the head of the Fourth Dynasty, nothing is known; his name, written Shura, occurs in the hieroglyphic inscriptions of tombs near the Pyramids of El-Geezeh, and was found by Mr Perring in the quarry-marks of the Northern Pyramid of Aboo-Seer, which was therefore his tomb.[17] In Manetho's list, according to Africanus, he was followed by two kings bearing the name of Sûphis, who may be called Sûphis I. and II.

Sûphis I., or Shufu, and Sûphis II., or Num-Shufu. Great Pyramid.

These correspond to the Shufu, or Khufu, and Num-Shufu, or Num-Khufu of the monuments. Since these names are found together, particularly in the quarry-marks of the Great Pyramid which has *two* principal chambers, and which all are agreed in assigning to the reign of *one* king, it is most reasonable to suppose that they ruled together for the greater part of their reigns. Manetho makes Sûphis I. to have ruled for 63 years, and Sûphis II. 66. The latter, therefore, probably reigned for some years after the former. Shufu must be the first of these kings, since he is the Cheops (Khufu) to whom Herodotus ascribes the building of the Great Pyramid, which, according to Manetho, was the work of Sûphis I.[18] This is the period at which we first find undoubted contemporary monuments of which we know the date, the earliest whereof is most probably the Northern Pyramid of Aboo-Seer before mentioned. Egypt.

the rule of the two Sûphises such monuments are extremely numerous[1] and afford us far better knowledge of the state of Egypt at that time than do the scanty remains of Manetho and the traditionary tales of Herodotus and Diodorus. The names of both the Sûphises occur among the rock inscriptions of Wâdee-el-Magharah in the Peninsula of Sinai, where the second of them, or Num-Shufu, is represented slaying a foreigner.[2] The military expeditions of the Egyptians, however, at this period were probably of little importance, and designed to repress the nomad tribes which have at all times infested the eastern and other borders of Egypt, and to maintain the possessions beyond these borders. The Memphite Pharaohs were rather celebrated for the arts of peace and for the care with which they promoted the interests of literature and science. Of Sûphis I. Manetho writes that he was arrogant towards the gods, but, repenting, wrote the Sacred Book.[3] This seems to agree well with what Herodotus and Diodorus relate of the impiety and cruelty of the king who built the Great Pyramid;[4] but if we suppose that he was arrogant towards the priests, we find a sufficient cause for the ascription to him of this character, so ill according with the prosperity and peacefulness of his time as shown by the monuments. The power of the king or kings is evidenced by the magnitude of the Great Pyramid, and the costly manner of its construction; the safety of the kingdom, by no soldiers being represented in the sculptures, and the general custom of going unarmed common to the great and the small; the wealth of the subjects, by the scenes pourtrayed upon the walls of their tombs; and the state of science and art, by the construction of monuments, gigantic in size, of materials many of which were transported from a great distance, and fitted together with an accuracy that has never been excelled, as well as by the astronomical and other knowledge, of which evidence is found in the contemporary inscriptions. After the Sûphises ruled Mencherês, called in the hieroglyphic inscriptions "Men-kau-ra," and by Herodotus "Mykerinos." By him the Third Pyramid was raised, in which the late General Howard Vyse found part of his mummy case, bearing his name, now in the British Museum.[5] According to Manetho, Queen Nitôkris, the last sovereign of the Sixth Dynasty, built this pyramid; but it should be observed that Eusebius's version of the lists seems to state this merely on the authority of tradition. It is most probable, from its plan, that the building was enlarged and a new passage and chamber excavated in the rock beneath it after its first completion, whence it seems that the later sovereign, by this additional work, made the tomb of Mencherês her own sepulchre also. Of the subsequent kings of the Fourth Dynasty, who were, according to Africanus's version of the lists of Manetho, four in number, nothing is known. The duration of the dynasty probably somewhat exceeded two hundred years, and it was succeeded by that called the Sixth, in like manner of Memphite sovereigns.

Mencherês, or Men-kau-ra. Third Pyramid.

Fifth Dynasty.

The Fifth Dynasty, of Elephantinites, commenced about the same time as the Fourth. The names of several of its earlier kings occur in the necropolis of Memphis, and sometimes with those of the contemporary sovereigns of the Fourth Dynasty.[6] The most important of these is Sephrês, the Shaf-ra or Khaf-ra of the monuments, the builder of the Second Pyramid. Herodotus calls him Chephrên,[7] and Diodorus Siculus, Kephrên.[8] The Elephantinite Dynasty lasted not much less than six hundred years, and appears to have consisted of thirty-one kings, the last of whom, called by Manetho Onnos, and in hieroglyphics Unas, was contemporary, as is shown by an ancient inscription, with Assa the fifth king of the Fifteenth Dynasty of Shepherds, ruling at Memphis.[9]

Sephrês, or Shaf-ra. Second Pyramid.

Onnos, or Unas.

Sixth Dynasty.

The Sixth Dynasty, by which the Memphite kingdom was ruled after the close of the Fourth, lasted about a century and a half. The most famous sovereign was the second of the line, Papa or Phiôps, who is related to have ruled a hundred years, a statement which the monuments seem to corroborate, although not directly. His sculptured records are numerous throughout Egypt, showing him to have been a powerful king, but not giving us any account of remarkable events during his reign. The second sovereign after him was Queen Nitôkris, called in the Royal Turin Papyrus, Neet-akartee. With her the Dynasty closed, Memphis being taken by the foreign invaders called Shepherds, whose first king made it his capital.[10]

Phiôps, or Papa.

Nitôkris, or Neet-akartee.

Ninth Dynasty.

Another royal line, that of the Heracleopolites, arose while the Sixth Dynasty ruled at Memphis. The time of the commencement of the first Heracleopolite Dynasty, the Ninth, is not certain, but it was probably not long after that of the Memphite Dynasty above mentioned. The names of six kings of the Ninth Dynasty have been found in hieroglyphics, and their order is shown by the list of the Chamber of Kings: all these bear the name of Nantef, excepting the fifth, who is called Munt-hotp. The king last mentioned seems to have been the most powerful of the six; his successor in the list of the Chamber of Kings receives a title equivalent to that of "chief," and his name appears not to have been inclosed in a royal ring. Munt-hotp was contemporary with the last king of the Eleventh Dynasty, and it is therefore probable that his successor was deprived of all but titular power by the potent head of the Twelfth Dynasty. After this time the monuments have not been found to afford us any information respecting the Heracleopolite kingdom. Probably the Ninth Dynasty lasted about four hundred years, and the Tenth nearly two hundred, terminating at the time of the great Shepherd war of expulsion, which resulted in the overthrow of all the royal lines except the Diospolite.[11]

Munt-hotp.

Tenth Dynasty.

Eleventh Dynasty.

With the Eleventh Dynasty commenced the Diospolite or Theban kingdom, which afterwards attained to greater power than any other, and had a longer uninterrupted duration. Its first dynasty was that called the Eleventh, the kings of which, excepting the last, seem to have been of little power, and are probably mentioned in subsequent inscriptions rather because they were the founders of the Diospolite line than as illustrious rulers. The duration of this dynasty is doubtful, and the time of its commencement has not been determined; it may be supposed that it began not long after the Ninth Dynasty. Amenemha I., its last sovereign, was a potent king who succeeded in a time of great disorder in establishing his kingdom as supreme in Upper Egypt. During part of his reign he was co-regent of Sesertesen I., head of the Twelfth Dynasty.[12]

Amenemha I.

Twelfth Dynasty.

The commencement of the Twelfth Dynasty forms an epoch in Egyptian history. Until then the country seems to have enjoyed a long period of prosperity, and then to have been suddenly surprised and subdued by a foreign force, which succeeded in gaining possession of Lower

Shepherd-invasion.

Egypt, and maintained itself for upwards of five centuries, being at length expelled, after a protracted struggle, which did not probably finally terminate until upwards of a century or even more after its power was broken. This period—that of the Shepherd-rule—lasting from the invasion of Egypt until the beginning of the Eighteenth Dynasty, under which the foreigners are generally held to have been ultimately forced to leave the country, was one for the most part of great suffering to the inhabitants; yet it comprehends the rule of many sovereigns, both native and foreign, of strength and wisdom; and there can be no doubt that it brought out those martial qualities which afterwards so greatly distinguished the Egyptian race.

Subjugation of Egypt.

The manner in which Egypt was subdued by the foreigners is not known for certain. Manetho states that they easily gained possession of the country without a battle. This success may have been partly owing to the undisturbed good fortune which preceded the invasion, but must have been also attributable to other causes; and it is not improbable that some one of the Egyptian kings had called in the foreigners as allies, or hired them as mercenaries, both dangerous expedients, more especially the latter, which is generally regarded as a symptom of a decaying state or a tyrannical government. Manetho relates that the Shepherds having subdued the country, burnt the cities, demolished the temples, aud treated the people with great barbarity. It is probable that this account of their conduct is somewhat exaggerated, having been coloured by the hatred which the Egyptians bore to the foreigners, and a recollection of the troubles of the great struggle which ended in their expulsion. At all events it is evident that they soon accommodated themselves to the manners of the Egyptians, adopted their religion, and endeavoured in every way to promote the welfare of the subjugated country. The race of the foreigners has been much disputed; the Egyptians

Origin of Shepherds.

called them "Shepherds" and "Hycsôs," or "Shepherd-kings," according to Manetho, who stated that "Hyk" signified "a king" and "Sôs" "a shepherd" and "shepherds;" but in another place, said that "Hyk" and "Hak" signified "captives." In hieroglyphics "Hak" is one of the names for "king," and "Huk" means a "captive;" but the second word of those composing Hycsôs, according to Manetho, is not found except in Coptic, in which language occurs the word *shωs*, "a shepherd." The most reasonable etymology seems to be "captive," that is, "foreign, shepherds;" for it should be observed that in the inscriptions foreigners are frequently called captives, and so represented on the monuments, when not actually such. In the inscriptions we find mention of "Shepherds," "Penu" (or "Phœnicians"), and "enemies" or "foreigners," the last-mentioned appellation being undoubtedly applied to Manetho's Shepherds. The Egyptian historian says that some said they were Arabs, and in his lists the kings of the first Shepherd Dynasty, the Fifteenth, are called Phœnicians. There is reason to suppose the latter statement to be true, and there is also evidence that some of the foreign race were Arabs, and certain of their kings, most probably of the Sixteenth Dynasty, appear to have been Assyrians.[1] Having said thus much respecting the establishment of the Shepherds in Egypt, we must return to the Diospolite kingdom.

Sesertesen I.

The first king of the Twelfth Dynasty was Sesertesen I., of whose long reign many records, but those chiefly of subjects, yet remain. The most interesting of the national monuments is a tablet found by Dr Ricci at Wadee Hâlfeh, in Nubia, near the Second Cataract, recording the king's triumph over foreign tribes, probably Ethiopians, and showing that at this early period the Egyptian rule had stretched thus far into Nubia.[2] For part of his reign Sesertesen I. was co-regent with Amenemha I., the last sovereign of the Eleventh Dynasty, and with Amenemha II. towards the close of his reign.

Amenemha II.

Under the latter king the first Tropical Cycle commenced B.C. 2005. Late in his reign he took as his colleague Sesertesen II.

Sesertesen II.

The next king, who probably was for part of his reign co-regent with Sesertesen II., was Sesertesen III., the Sesôstris of Manetho.

Sesertesen III., Manetho's Sesôstris.

This name of Sesôstris is applied by ancient historians to several kings. It is probably derived from Sesertesen: other derivations have indeed been proposed, but none of these is equally satisfactory.[3] We can recognise an early Sesôstris, that is, Sesertesen III., and a later one, Rameses II., of the Nineteenth Dynasty, and it is not unlikely that Sesertesen I. is also spoken of under this name. If this supposition be correct, we may distinguish the two very ancient kings as Sesôstris the conqueror, or Sesertesen I., and Sesôstris the lawgiver, or Sesertesen III. In Manetho's lists we find, after a short account of the conquests of Sesôstris, which seems inapplicable to this king's reign, that he was considered by the Egyptians as "after," or "the first after," Osiris;[4] which may be explained by concluding that he was regarded by them as the greatest of mortals, and to be honoured next to Osiris, "the youngest of the gods." In ancient sculptures in Nubia we find kings of the Eighteenth Dynasty, of the Thothmes family, worshipping Sesertesen III. as a god, and this is *the only case* of the kind. We find indeed one solitary instance of another early monarch being thus worshipped in later times, and some examples of several monarchs being worshipped together, and several cases of kings worshipping their fathers or other progenitors, but, as far as has been ascertained, no example of a king of any dynasty being frequently represented as a god, and worshipped, in sculptures of other kings not of the same dynasty. The monuments thus seem to indicate that Sesertesen III. is Manetho's Sesôstris. Sesertesen II. was apparently a king of little note, and it is improbable, notwithstanding his name, that anything ascribed to Sesôstris by those who confounded different kings under that name applies to him. During the reign of Sesertesen III. the First Phœnix Cycle commenced, B.C. 1986.

Amenemha III.

The next king was Amenemha III., of whom we are told in the lists that he built the Labyrinth in the Arsinoïte nome as a tomb for himself. His prenomen reads Ra-en-ma or ma-t, or Ma-en-ra or Ma-t-en-ra, and from it most probably originated the Mœris of the Greeks. Mœris seems, like Sesôstris, to have been a name applied to more than one sovereign; but there can be no doubt that the principal person intended by it was this king, for the Greeks ascribe to him the building or founding of the Labyrinth, and his name has been discovered by Dr Lepsius in the sculptures of the ruins of that structure or its pyramid.[5]

Amenemha IV. Ra-sebak-nufret.

After the reigns of two other sovereigns Amenemha IV. and Ra-sebak-nufret, who was, according to Manetho, as preserved by Africanus, a queen, the sister of her predecessor, the dynasty came to a close. It is probable that these two ruled with Amenemha III., as successive co-regents, perhaps towards the close of his reign. This dynasty lasted about 160 years: Africanus assigns to it, in his version of Manetho's list, exactly that duration, and the monuments and Royal Turin Papyrus afford confirmation of this sum.[6] At its termination the power of the Diospolites became greatly diminished, and did not recover until the beginning of the Eighteenth Dynasty.

Fourteenth Dynasty.

The Fourteenth Dynasty, or Xoïte kingdom, seems to have arisen with, or during, the Twelfth Dynasty. It had its seat of government at Xoïs, a town of Lower Egypt in the northern part of the ancient Delta. Seventy-six kings

---

[1] See Manetho in Cory's *Ancient Fragments*; and *Horæ Æg.*, p. 148.

[2] Rosellini, *Monumenti Storici*, No. xxv., 4.

[3] A derivation lately suggested by the Vicomte de Rougé is very ingenious, and more probable than any other except that from the name Sesertesen. See the *Athenæum Français*, 1854, No. 48, p. 1128.

[4] *Ancient Fragments*, pp. 110, 111.

[5] Lepsius, *Denkmäler*, abth. ii., bl 140.

[6] For the chronology and history of this dynasty, see *Horæ Æg.*, p. 155.

Egypt. are assigned to this line, and a duration of either 184 or 484 years. The latter sum is the more probable if the number of kings be correct. Supposing, then, that the Fourteenth Dynasty lasted for nearly five centuries, it probably terminated during the great Shepherd war, and perhaps some years before the beginning of the Eighteenth.[1]

Shepherd kings. According to Africanus, three dynasties of Shepherd kings ruled in Egypt, the Fifteenth, Sixteenth, and Seventeenth. Eusebius, however, makes but one of these dynasties, the Seventeenth, to have been of the foreign invaders, while he assigns to it kings who are of the Fifteenth in Africanus's list. According to Josephus, the Shepherds ruled 511 years, until the great war commenced which terminated in their expulsion from Egypt. The monuments, as well as internal evidence, are in favour of Africanus's version instead of that of Eusebius, and it is therefore generally preferred. Admitting, then, that there were three Shepherd dynasties, we must next inquire what was the period of their rule. In the list of Africanus the sum of the three is 953 years, which, if correct, would prove that they could not have been successive. That it is correct is most probable, and that the Fifteenth Dynasty was contemporary with the earlier portion of the Sixteenth, and the Seventeenth with the later portion of the same dynasty, the Seventeenth Dynasty being, however, separated from the Fifteenth by a Memphite dynasty or dynasties.[2]

Fifteenth Dynasty. Salatis. The Shepherd kings of the Fifteenth Dynasty were the greatest of the foreign rulers. The first of these, Salatis or Saïtês, was made king, according to Manetho, after the conquest of the country (*cir.* B.C. 2080). "He lived at Memphis, making the Upper and Lower Country to pay tribute, and placing garrisons in the most fit situations." Of these the greatest was Avaris, an old city, to the east of the Pelusiac Branch, which he rebuilt and fortified strongly, placing in it an enormous garrison.[3] His object was to defend the frontier against the Assyrians, who, Manetho tells us, he foresaw would have a desire to invade his kingdom. Salatis died after an active reign of nineteen years.[4] In the lists he and his successors are called Phœnicians, and it is very probable that they were of that race. His nomen is not found in the hieroglyphic inscriptions, but his prenomen occurs both on a contemporary monument and in the Royal Turin Papyrus.[5]

Pi-ankhee, or Bêôn. The successor of Salatis was Bêôn, in the hieroglyphics Pi-ankhee, and he was followed by Apachnas, whose nomen is found only in the Royal Turin Papyrus, and is of doubtful reading. The next king was Iannas, called on the monuments A-an, to whom succeeded Assis, whose hieroglyphic name is Assa. There are several tombs of the time of this king in the necropolis of Memphis, from the sculptures and inscriptions of which we obtain great insight into the state of the Shepherd kingdom under his rule.[6] In the sculptures we see the same evidences of the prosperity and wealth of the subjects as in those of the period of the Fourth Dynasty. The foreigners appear to have adopted the Egyptian dress and manners so completely that we do not find a single foreign name. In one tomb the inscriptions show that the Shepherd kings of this dynasty held Leontopolis or the Leontopolite nome in the eastern part of the ancient Delta, which shows that their dominion must have been extensive.[7] Most probably Assa was the Pharaoh of whom Joseph was the prime-minister, the patriarch receiving that appointment towards the close of his reign, and continuing to hold it in the next reign. The reasons for this opinion will be given a little later. Of the last king of the Fifteenth Dynasty, the successor of Assa, the monuments tell us nothing, and it is not even certain that his name has been found in hieroglyphics or hieratic. In Manetho's lists he is called Aphôbis or Apôphis. With him the greatest Shepherd Dynasty came to a close, and Memphis was again the seat of native kings. If Dr Brugsch's view be correct, Apôphis reigned just before the Eighteenth Dynasty, no doubt after the Shepherds had lost Memphis.[8]

A-an, or Iannas. Assa, or Assis.

Thirteenth Dynasty. After the end of the Twelfth Dynasty, about B.C. 1920, the Diospolite kingdom was ruled by the Thirteenth, which lasted about 400 years, until the commencement of the Eighteenth Dynasty. The kings seem to have been of little power, for the most part, and probably tributary to the Shepherds. They possessed, however, a considerable tract south of Egypt; and this may be supposed to have been an asylum for them during the troublous period of their rule. All the names of these kings have not been found, and those which are known are chiefly prenomens, and not nomens; many of the latter appear to have been Sebak-hotp and Nufre-hotp.[9] The Fourteenth Dynasty, or Xoïte Kingdom, has been already noticed.

Eighth Dynasty. The Eighth Dynasty, of Memphites, succeeded the Fifteenth, and ruled, according to Africanus's version of Manetho's List, nearly a century and a half. It is not certain whether the Seventh Dynasty, likewise of Memphites, to which the same version assigns a duration of only 70 days, intervened between the Sixth and Fifteenth Dynasties, or the Fifteenth and Eighth.[10] The native successors of the Shepherds at Memphis seem to have been princes of little power and contracted dominions. The Shepherds of the Sixteenth Dynasty appear to have succeeded to the political position of those of the Fifteenth. It is very remarkable that in the Royal Turin Papyrus among kings who must be assigned to this dynasty or the Seventeenth are certain who appear to be Assyrians, and one of these is probably a Pharaoh who oppressed Israel, the predecessor of him who was drowned in the Red Sea. Indeed there are strong grounds for supposing that this dynasty was composed of kings of a different race or races to those of the Fifteenth, and bitterly opposed to them; and that when the rule of the latter came to a close they seized their possessions in the eastern part of the Delta, and persecuted the Israelites who had been favoured by the earlier sovereigns. Of the Seventeenth Dynasty nothing is known, except that its kings were Shepherds. Africanus's version indeed makes them to have been co-regent Diospolites and Shepherds, but this is generally held to be a mistake.[11]

Seventh Dynasty.

Sixteenth Dynasty.

Seventeenth Dynasty.

Shepherd war. From the time of Assa to the commencement of the Eighteenth Dynasty, a period of about three centuries and a half, scarcely any monuments have been discovered, and this indicates that Egypt was then in a weak and distracted condition,[12] and agrees with the statement of Manetho, that after the Shepherds had ruled Egypt for 511 years, the kings of the Thebaïs and of the rest of Egypt made an insurrection against them, and a great and long war raged between them.[13] The kings here meant must have been a Diospolite of the Thirteenth Dynasty, probably with a Heracleopolite of the Tenth, and a Xoïte of the Fourteenth. The great war thus commenced had resulted at the beginning of the Eighteenth Dynasty in the restoration to Egyptian

Egypt.

rule of nearly all Lower Egypt; and the other lines having then come to an end, the whole power was centred in the Theban monarchy. It was, however, probably more than a century before the foreigners were finally expelled.

Connection of the Israelites and Greeks with Egypt.

Before noticing the history of the Eighteenth Dynasty, it is necessary to mention briefly the connection between the Israelites and the Egyptians, and between the Greeks and the Egyptians. The sojourn and exodus of the Israelites have been variously assigned to the time of the Dynasties preceding the Eighteenth, and to that or the following Dynasty; and this is, therefore, the proper place in which to notice some of the grounds on which these different opinions rest. Certain of the Greek traditions point to the Shepherd-period, if there be any truth in their approximative chronology; and these, therefore, likewise here demand a brief consideration.

Date of Exodus.

A wide difference has prevailed among critics respecting the date of the Exodus, and the length of time for which the Hebrews sojourned in Egypt before that event. Some, rejecting all the numbers mentioned in the Bible by which the time of the Exodus has been usually computed, take the genealogies as their guides, and calculate that event to have occurred about 1300 B.C.; others, following Archbishop Ussher, place it B.C. 1491; and others, agreeing with Dr Hales, carry it back to the middle of the seventeenth century. The last view, which is in accordance with the opinions of several of the early Christian chronologers, is supported by evidence not easily shaken, which may be thus stated:—1. The numbers of years occurring in the Book of Judges added together, and St Paul's statement that the Israelites were ruled by judges for "about the space of four hundred and fifty years, until Samuel the prophet,"[1] would carry up the date of the Exodus to about B.C. 1650. The mention in Jephtha's message to the king of the Ammonites that Israel had already dwelt 300 years in the trans-Jordanite possessions,[2] is agreeable with this date of the Exodus and with Ussher's, but not with that of about B.C. 1300. Against the date of about B.C. 1650 may, however, be urged the statement in the first Book of Kings,[3] that the temple was commenced by Solomon in the 480th year after the Exodus, which is the basis of Ussher's computation; but this number is given differently in the Septuagint version as 440 years, and it cannot be reconciled with the period mentioned by St Paul, nor, except by an arbitrary arrangement, with the numbers given in the Book of Judges. 2. A comparison between the Hebrew calendar and the Egyptain leads to the same results as do the data mentioned under the previous head. The ancient Hebrew civil year commenced about the time of the autumnal equinox; and we find that at the approximative date of the Exodus obtained from the numbers given in the Book of Judges, the Egyptian Vague Year commenced at or about that period. This approximative date, therefore, falls about the time at which the Egyptian Vague Year and the civil year of the Hebrews nearly or exactly coincided in their commencements. It may be supposed that the Israelites had made use of the Egyptian Vague Year, which, indeed, is rendered not unlikely by the circumstance that they had for the most part adopted the Egyptian religion,[4] the ceremonies of which were regulated by the months of that year. The ordinances of the Law, however, made it necessary that the Israelites should use a year virtually solar, and such a year was at the time of the Exodus either restored or instituted. But the inquiry may be carried farther; for, if the Egyptian and Hebrew months corresponded, the fourteenth day of Abib, on which fell the full moon of the Passover of the Exodus, corresponded to the fourteenth day of Phamenoth. Now, a full moon fell on the fourteenth day of Phamenoth, or Thursday, April the 21st, in the year B.C. 1652. A full moon would not fall on the same day of the Vague Year at a shorter interval than 25 years before or after B.C. 1652; and the triple coincidence of the occurrence of a full moon on a certain day of the Vague Year, with reference to the autumnal equinox, could not recur in less than 1500 Vague Years. 3. There are certain indications which would induce us to place the commencement of the first sabbatical period in the year B.C. 1605, and since the Exodus took place 47 years previously, to date the latter event B.C. 1652. The inquiry which leads to this result is very intricate, and the result cannot be regarded as more than hypothetical; yet it should be remembered that it is founded on evidence totally distinct from that adduced under the preceding heads. 4. To the Israelites in the desert a command was given "that they make them fringes to the borders of their garments throughout their generations, and that they put upon the fringe of the borders a ribband of blue,"[5] as a memorial of the covenant.[6] In an Egyptian battle-scene representing, in the great temple of Aboo-Simbel, the capture by Rameses II. of a stronghold in or near Palestine, probably that called in the hieroglyphics Ketesh, which corresponds to the Ashteroth-Karnaim mentioned in the Bible, a peasant is pourtrayed driving away some cattle. His dress has a blue stripe resembling a ribband near its border, and a blue fringe, and his physiognomy is not unlike that of the Jews.[7] This seems to afford strong evidence that Rameses II. reigned subsequently to the Exodus. The date of the campaign to which this sculpture relates may be placed about B.C. 1300, or not more than a few years later at the utmost. The Exodus, therefore, on this ground, appears to have taken place in or before the year B.C. 1340, and certainly prior to the reign of Rameses II. This result would show that those who hold the latest date of the Exodus—that deduced from the genealogies—are wrong in assigning the event to the reign of Men-ptah, the successor of Rameses II.; and it is in opposition to their best argument that the city Raamses or Rameses, built or fortified during the oppression,[8] was named after Rameses I., or his grandson Rameses II., since the oppression would probably have ended before the accession of the former king. The weight of evidence, therefore, is in favour of the earliest of the dates mentioned above, that of B.C. 1652. Respecting the duration of the sojourn of the Israelites in Egypt, the sum of 215 years seems, on the whole, far preferable to 430; but there is not space here for the discussion of the question. Admitting then that Joseph's government probably began B.C. 1876, that Jacob came into Egypt B.C. 1867, and that the Exodus took place in the year B.C. 1652, these data may be applied to Egyptian history with a view to test their accuracy.

Joseph governor of Egypt.

Granting these premises, Joseph became governor of Egypt towards the close of the reign of Assa or Assis, the fifth king of the Fifteenth Dynasty and this Shepherd king would well correspond to the Pharaoh mentioned in the Bible, as the most powerful sovereign not of those of the Lower Country only but of all Egypt. Various passages in the Bible-narrative seem to confirm this view, which is most agreeable with the testimony of the monuments; for an Egyptianized foreigner would be far more ready to favour the strangers than would a native Egyptian. The Fifteenth Dynasty was followed, after perhaps the seventy days' rule of the Seventh, by the Memphite line of the Eighth Dynasty, about the time of Joseph's death. The kings of the Eighth Dynasty seem, however, to have been of little strength, and it appears that the Shepherds of the Sixteenth Dynasty succeeded to much of the power of the rulers of the Fifteenth. We cannot suppose the new

Egypt.

Oppression of the Israelites.

king, which knew not Joseph, and the other oppressors of the Israelites, to have been of the Eighth Dynasty, for this was a line of Memphite kings, and it is said in the Bible, "My people went down aforetime into Egypt to sojourn there; and the Assyrian oppressed them without cause:"[1] from which we must infer that at least one of the Pharaohs of the oppression was an Assyrian. Now, in the list of kings called the Royal Turin Papyrus, among the names of a dynasty of foreigners, which could not have been the Fifteenth, and was therefore either the Sixteenth or Seventeenth, occur those of Assyrian kings.[2] One of these, who bears the name of Uben-ra (a name likewise borne by two other kings of the same period, as well as found on one of the Nemrood ivories in the British Museum, and likewise taken as a foreign title, in the feminine Ubent, by the Semiramis who ruled in Egypt[3]), appears to have reigned forty years (the number is imperfect, but is probably forty), while to his successor is assigned a reign of but one year. And the Bible-narrative seems to indicate that the Pharaoh from whom Moses fled to Midian reigned at least forty years, while it is quite clear that his successor, who was drowned in the Red Sea, must have reigned about a year, somewhat more or less. These circumstances seem to confirm the early date of the Exodus, no less than others. Among the latter may be particularized the subsequent policy of the Egyptians and Assyrians towards the Israelites, and the friendship of the Israelites and the Egyptians in after times, as well as the many difficulties in accepting the later dates which arise from the absence of any mention of the sojourn and Exodus on monuments supposed to be contemporary.[4] The friendship of the native Egyptian and Ethiopian kings, without any known exception, for Shishak and his family were partly, at least, of Assyrian or Babylonian origin, and the constant enmity with which the Israelites were regarded by the Assyrians and Babylonians, are satisfactorily explained by our finding that the Assyrians oppressed both the Israelites and the Egyptians in Egypt. For it is evident that the Shepherd kings of the period which followed the Fifteenth Dynasty, or, at least, those after Assa, were those whose memory was so hateful to the Egyptians. It must also be borne in mind that many of the Shepherds must have been Egyptianized; like Moses, whom the daughters of the priest (or prince) of Midian thought to be an Egyptian; and that they were evidently so mixed up with the Egyptians of Lower Egypt as to be, under Shepherd rule, almost one people; and thus one can understand their being generally, though not always, mentioned as Egyptians, or not as distinct from them, in the Bible. Probably the Egyptians joined with the oppressors of the Israelites sometimes without being forced to do so, for they were included in the same punishment; yet their conduct towards them in after times, and the remarkable command in the law, "Thou shalt not abhor an Egyptian, because thou wast a stranger in his land," to which it is added that their children, like those of Edomites, should enter into the congregation of the Lord in their third generation,[5] whereas Amalekites could never be admitted, both tend to show convincingly that the Egyptians had in many instances treated the Israelites with kindness while they sojourned in their land; and the punishment which partly fell upon them may have been in their case rather for idolatry and vice than for oppression. The inference thus drawn from the passage in the Book of Deuteronomy is strengthened by an examination of what precedes it; for there are three other nations only mentioned, the Moabites, Ammonites, and Edomites, of which the last were admitted to the same privilege as the Egyptians, though the other two were excluded. The reason of their exclusion is alone mentioned: it was their inhospitality to the Israelites when they came out of Egypt, whereas the Edomites, we know, treated them hospitably. In reviewing the subsequent history of Egypt, we cannot fail to be struck with the constant amicable feeling which subsisted between the Israelites and the Egyptians. The capture of Gezer, a Canaanite town, by one of the Pharaohs, without opposition on the part of Solomon, and the giving of that city to his daughter, Solomon's Egyptian queen, and that marriage itself, show what a friendly alliance existed in those days. And in later times, though we may think that the policy of Tirhakah and Apries was dictated by a regard to their own interests, Neco appears to have been unwilling to add the rich kingdom of Judah to his dominions, when Josiah disputed his passage to the Euphrates. The conduct of Shishak was far different, but he was, as already remarked, of a line partly at least of Assyrian or Babylonian origin, and his policy was that of an Assyrian or Babylonian prince. These matters have been dwelt upon in some detail, but their importance, as tending to establish a synchronism between Hebrew and Egyptian history, make it impossible to pass them by without something more than a mere notice.

Policy towards the Israelites.

Civilization of Greece from Egypt.

The traditionary accounts of the civilization of Greece by colonists from Egypt are so obscure, and so interwoven with undoubted mythological relations, that some have rejected them as either false or doubtful. Yet it is hard to believe that the traditions of any nation respecting their ancestors are altogether unworthy of reliance; and our wisest plan is to endeavour, by a comparison of the monumental data in Greece and Egypt, first to ascertain whether there is any truth in these traditions, and then to separate that truth from the error which surrounds it. Greek art affords evident traces of Egyptian influence, if not rather of an Egyptian origin; a column resembling the Doric being found in the rock tombs of Benee-Hasan, which were excavated about the time of Abraham. The earliest Greek pottery affords still stronger evidence in bearing patterns and devices of an unmistakable Egyptian origin, and especially one which is imitative of a well-known hieroglyphic group. This shows that the two countries must have been connected at least as early as the time of Homer, and probably as far back as the date to which the taking of Troy is usually assigned. Then, again, we find on an Egyptian monument of about B.C. 1200 a sea-fight represented between Cretans and Carians on the one side and Egyptians on the other, a circumstance which confirms the Greek tradition that the Cretans held the empire of the sea in ancient times, and lost it not long before the siege of Troy, likewise indicating in what manner their maritime power was broken. This case warns us not to disregard even earlier traditions, especially as they also are very consistent with the history of Egypt at the period to which they relate, and were received by the learned Greeks and Egyptians of subsequent times. We may admit that many colonists went from Egypt to Greece during the Shepherd rule, carrying arts and sciences to the rude inhabitants of Hellas. These emigrations commenced at least as early as the middle of the nineteenth century before our era, and continued as late as the close of the sixteenth, if, as we may suppose, there be any truth in the approximative chronology of the traditions. The kings of the Fifteenth Dynasty are said to have been Phœnicians, and many of their people seem to have been of the same race: thus we see wherefore certain of the colonists are made both Phœnician and Egyptian, for, as evidently in the Bible, Shepherds are often called Egyptians. Towards the close of the Fifteenth Dynasty many of the Shepherds would seem to have sought a home in Greece; and when the great war had commenced these emigrations appear to have become more frequent, until after the time when the foreigners were finally expelled Egypt, when notice of them ceases.

War of the Egyptians with the Cretans and Carians.

Colonization of Greece from Egypt.

Egypt.

The history of the Shepherds in Egypt, and the traditions of the colonization of Greece, agree so well that the only difficulty to one's mind is to understand how so much truth can have been preserved amidst the myths and exaggerations of the ancient Greeks. Thus much may be safely affirmed, but the details of the traditions must be regarded with great caution, lest by hastily accepting them, as did most critics until lately, the truths with which they are interwoven should appear perplexed and doubtful, and historical scepticism take the place of justifiable circumspection.

Eighteenth Dynasty.

With the Eighteenth Dynasty, about B.C. 1525, a new period of Egyptian history commences, new in the abundance of materials for its reconstruction, and in the greatness of the monarchy whose fortunes it relates. The sources of information are no one connected history, but numerous inscriptions, sculptures, and papyri, whence we can gather many of the remarkable events by which this and the succeeding dynasty were distinguished.

Aah-mes.

The first king of the Eighteenth Dynasty was Aah-mes, whom Manetho called Amôs or Amôsis. No great monuments of his reign remain, but from various inscriptions we must infer that he was a powerful king, and that in his time the Shepherds had quitted the greater part of Egypt. Two records of especial interest may be particularized. One is a long inscription in the tomb at Eilethyas of one Aah-mes, chief of the mariners, who served several of the early kings of the Eighteenth Dynasty, having commenced his career under King Aah-mes. The inscription speaks of war at sea, or on the river, mentions the famous Shepherd-city Avaris, and relates that the king made in his sixth year an expedition by water to Ethiopia to impose tribute.[1] The other record is a tablet at the quarries of El-Ma'sarah, a little above Cairo, on the east bank of the river, opposite Memphis, which relates that in the twenty-second year of his reign Aah-mes cut stone for the temple of Ptah, most probably at Memphis, and for that of Amen at Thebes. These inscriptions show that Aah-mes must have ruled nearly all Egypt, and thus explain why some (as it appears, but it is a disputed point) supposed him to have finally expelled the Shepherds.

Amenoph I.

Amenoph I., the successor of Aah-mes, was at least as potent a king, and the memorials of his reign are more numerous. They are chiefly found in the representations or paintings of the tombs of his subjects; but chambers in the more ancient portion of the great temple of Amen-ra, now called that of El-Karnak, at Thebes, show that he did not neglect public edifices.[2] He was evidently successful in wars against the Ethiopians as well as against Asiatics.

Thothmes I.

To him succeeded Thothmes I., in whose reign the arms of Egypt were carried into Mesopotamia, for one of his officers has left an inscription recording that he brought booty thence.[3] The same king warred in Ethiopia also.[4] In the great temple at Thebes he made additions, and, in particular, set up there two obelisks of red granite, of which one yet stands.[5]

Thothmes II.

Under the next sovereign, Thothmes II., the prosperity of Egypt continued, and the extent of his kingdom is proved by his name being found as far south as Napata (Gebel Berkel), in Ethiopia.[6]

Amen-numt, a Semiramis.

With him was associated in the government a Queen Amen-numt, who appears to have possessed much greater power than he, if not to have ruled solely while he was but nominally a king. For at least 16 years, that is, for the whole of the reign of Thothmes II. and the first 3 or 4 years of that of Thothmes III., this queen continued to govern, and left many beautiful monuments to attest her magnificence and power, chiefest of which are the lofty obelisks of the temple of Amen-ra at Thebes, one of which is still standing,[7] while the other is fallen and broken in pieces. Queen Amen-numt is called the daughter of Thothmes I., and the sister of Thothmes III., and therefore of Thothmes II. also; but she appears to have been a foreigner, and if so, only related to the Egyptian royal family by marriage, unless her mother was likewise a foreigner, and a wife of Thothmes I. Several circumstances seem to show that she was a Semiramis, for one cannot say Semiramis simply, since more than one sovereign appears to have been intended by the name, as in the case of Sesôstris. The strongest reasons in favour of this opinion are founded on the circumstance that Queen Amen-numt is constantly represented in the sculptures as wearing male attire, that she receives in one instance what we may almost conclude to be an Assyrian title "Ubent" as her appellation "in the foreign land," and that her name was afterwards effaced from the monuments; particulars which are strikingly in accordance with the statement that the Assyrian Queen Semiramis, who dressed as a man, subdued Egypt. It may be added that the time of Amen-numt is not far anterior to the approximative date of a Semiramis obtained from the fragments of Berossus.[8]

Thothmes III.

Thothmes III. appears soon to have emancipated himself from the control of Queen Amen-numt. His reign was marked by many successful expeditions conducted by him in person, in one of which he penetrated as far as Nineveh, though it is not said whether he besieged that city or not.[9] If Manetho be accurate, the most important military event must, however, have been his successful war with the Shepherds, who, according to that historian, were driven by him out of all Egypt excepting the stronghold of Avaris on the frontier.[10] Many monuments, especially at Thebes, remain to prove the greatness of this king and the wealth of his subjects. The tombs of private persons are not the least interesting of these memorials, and afford, in the representations which adorn their walls, very beautiful specimens of ancient Egyptian painting. Indeed, the reign of Thothmes III., with that of Thothmes II. preceding it, and those of Amenoph II., Thothmes IV., and Amenoph III. following it, may be considered as comprising the best period of art, all the earlier time showing a gradual improvement, and all the later a gradual declension. We do not, however, trace a very marked falling away until the power of Egypt had begun to decline, full two centuries later than the end of Thothmes III.'s reign.

Amenoph II.

Of Amenoph II., the son and successor of Thothmes III., little is known, and we can scarcely err in supposing his reign to have been short and unmarked by very important events.

Thothmes IV.

Departure of Shepherds.

In the reign of Amenoph's son Thothmes IV., occurred, according to Manetho, the departure of the Shepherds from their last possession in Egypt.[11] The Egyptian historian relates that having unsuccessfully beleaguered Avaris, the stronghold of the foreigners, Thothmes agreed to terms, and the Shepherds were permitted to leave the country unmolested with their families and effects. The monuments have not been found to allude to this event, and they tell us little of this reign, but that little shows that, short as it evidently was, it was marked by prosperity and success.

Amenoph III.

Thothmes IV. was succeeded by his son Amenoph III., one of the most illustrious kings of the best period of Egyptian history. In his time we find a distinct record of the extent of the kingdom, which is stated to have had Nehereena (Mesopotamia) as its northern boundary, and Keruee or Keluee (probably Coloe) as its southern.[12] Although it does not distinctly appear whether these are to be understood as the outermost provinces or as the lands bounding those provinces, and although the southern boundary cannot be

Egypt.

positively ascertained, yet we can gain some idea of the power of Egypt from the inscription. Syria, west of Euphrates, obeyed Amenoph III., and a very great part of Ethiopia; and that the latter was the case is proved by monuments and their inscriptions in that country, and records of his successes in the inscriptions of Egypt. It is remarkable that he seems from his physiognomy to have been partly of Ethiopian origin. His long reign of nearly forty years, at the least, was marked by the construction of magnificent temples. Of these the greatest were two at Thebes; one on the west bank, of which scarce anything remains but the two great colossi which stood on each side of the approach to it, and one of which is famous as the Vocal Memnon. On the opposite bank he likewise built the great temple now called that of El-Uksur, which Rameses II. afterwards greatly increased in size. It is almost needless to remark that the identification of this king with Memnon by the Greeks, apart from the circumstance that other Pharaohs were so called by them, is of no historical value. The tomb of Amenoph III. yet remains at Thebes in the Western Valley near that of the tombs of the kings.

Rule of Sun-worshippers.

After the reign of Amenoph III., the tranquillity of Egypt was disturbed by the rule of the chiefs of stranger settlers, foreign princes, who were allied to the Egyptian royal family. Whatever may have been their title, it is evident that the Egyptians regarded them as usurpers, and that they were unable to maintain themselves but by a rigorous military despotism. Their monuments have been found in all parts of Egypt, but much defaced or entirely ruined by the enmity of the Egyptians. We learn, however, that they abandoned the Egyptian religion, and set up in its place sun-worship; that they built a city in Middle Egypt, near the modern village of Tel-el-'Amarineh; and raised temples at Thebes and elsewhere. Manetho appears to have noticed their rule, for Eusebius, in the second part of his chronicle, mentions that during the reign of Amenophis (Amenoph III.) "the Ethiopians, migrating from the river Indus, came and dwelt near to Egypt;" and in the catalogue of kings of Egypt by an anonymous author, given by Syncellus, we find the following passage immediately before the mention of Oros, Amenoph's son and legitimate successor:—"The Ethiopians, coming from the river Indus, settled near to Egypt." It is highly probable that this statement was originally derived from Manetho, though evidently altered by misapprehension. Our finding that Egypt and Ethiopia were under the power of foreign chiefs at about the time indicated does not permit us to doubt that the statement was founded on fact. These sun-worshippers appear therefore to have belonged to the race which may be called that of the Eastern Ethiopians, a people who, in the time of the Greek geographers, dwelt between Persia and the Indus, and whom Herodotus describes as lank-haired to distinguish them from the Ethiopians of Africa.[1] Bunsen and Lepsius suppose their rulers to have been heretical Egyptian princes, but it is plain that both chiefs and people were of a race far different from that of the Egyptians, although their chiefs were allied with the Egyptian royal family. Sir Gardner Wilkinson, not without strong reason, assigns Amenoph III. to this foreign race; but if he be right in this opinion we may notwithstanding date the commencement of their rule from the end of his reign, as then began that change of the state religion which was the great peculiarity of the foreign domination. Several kings of this race ruled after Amenoph III., of whom the most important was Amenoph IV., or Bekh-en-atenra. They have not as yet been classed in order, although much has been done towards effecting this desirable object by Sir Gardner Wilkinson and also by M. Prisse. The duration of their power probably did not much exceed thirty years. The religion of these foreigners is a matter of great interest, as it presents us with a very ancient example of pure sun-worship. The sun is represented as adored by them under the form of a disk whence issue numerous rays, each terminating in a human hand, one of which presents to the worshipper the symbol of life. It appears that they adored one god, whom they supposed to be resident in the sun, and operating through its rays; and that they worshipped this god through the medium of the sun and its rays. These particulars may be compared with the "Chaldean Oracles of Zoroaster," as given by Cory in his *Ancient Fragments*.[2] Although many of these "Oracles" must be of late origin, and others must have suffered by translation into Greek, they certainly contain many principles of the old religion of Zoroaster, and it is not therefore surprising that we should find in them remarkable agreements with the records of the sun-worshippers. The following couplet reads like a description of the representation of the sun worshipped by the foreigners as described above:

Their religion.

"It becomes thee to hasten to the light and *rays* of the Father,
From whence was sent to thee a *soul*, endued with much mind."

Χρὴ σε σπεύδειν πρὸς τὸ φάος καὶ πατρὸς αὐγὰς
Ενθεν ἐπέμφθη σοι ψυχὴ, πολὺν ἑσσαμένη νοῦν.[3]

Har-em-heb.

Precisely how and when the sun-worshippers were expelled from Egypt or destroyed, does not appear; though it can scarcely be doubted that Oros, the Har-em-heb of the monuments, who succeeded them, was the prince by whom they were overthrown.[4] Har-em-heb was a son of Amenoph III., and with him was continued the legitimate line of Diospolite sovereigns. The records of his reign are comparatively unimportant; and if Manetho be right in assigning to him a rule of between 36 and 37 years, as the best readings inform us, it must be supposed that for the greater part of this period he did not rule, or governed but a portion of the country, but that, counting from the close of his father's reign, he included the time that the sun-worshippers held the supreme or chief power during his own nominal or contemporaneous reign. The sculptures of a rock temple at Silsilis, Gebel-es-Silsileh, commemorate a successful expedition against the negroes.[5]

Rameses I. Nineteenth Dynasty. Sethee I.

Oros was succeeded by Rameses I., of whose very short reign no important details have reached us. After him his son, Sethee I., one of the greatest of the Pharaohs, ascended the throne. The exact duration of his reign, which must have been long, is uncertain, and probably for part of it he ruled jointly with his son Rameses II. His accession may be placed about B.C. 1340, which is therefore the approximative date of the commencement of the Nineteenth Dynasty; for Manetho makes him head of that line, a position which should rather, one would think, have been assigned to his father Rameses I. The most important architectural work of his reign yet remaining is the magnificent hypostyle hall in the great temple of El-Karnak, on the outside of the north wall of which is a highly interesting series of sculptures representing the great achievements of his arms.[6] His tomb, which is generally known as "Belzoni's," from its discoverer, is the most beautiful of those in the valley of the tombs of the kings; and its size shows that his reign must have been a long one, for it is well known that the sepulchre of an Egyptian king was usually commenced at or not long after his accession, and thus indicated the duration of his reign. The most important of the military exploits of Sethee I. appears to have been the conquest of the Kheta or Hittites, and the capture of their great stronghold Ketesh, or Ashteroth-Karnaim. It should also be noticed

that he expelled certain foreigners of the race of the "Shasu" from the city of the Lion, or Leontopolis, near the eastern frontier of Lower Egypt.[1]

Rameses II.

Rameses II., who succeeded his father, Sethee I., probably after having ruled jointly with him for some time, was the most illustrious of the ancient kings of Egypt. It is he who is generally intended by the Sesôstris of the Greek and Roman writers. His reign lasted, according to Manetho, if we follow what seem the best readings, a little above sixty-six years, and was marked by great success in war and by the construction of magnificent edifices. Among the latter may be mentioned at Thebes the great temple, commonly called the Memnonium, but more appropriately the Rameseum of El-Kurneh, on the western bank, one of the most beautiful of Egyptian monuments, and a great part of the temple of El-Ūksur on the opposite bank, as well as additions to that of El-Karnak. Throughout Egypt and Nubia are similar memorials of the power of Rameses II., one of the most remarkable of which is the great rock temple of Aboo Simbel, not far north of the Second Cataract. The temple of Ptah at Memphis was also adorned and enlarged by this Pharaoh, and its site is chiefly marked by a very beautiful colossal statue of him, fallen on its face, and partly mutilated. The numerous monuments of Rameses II. and a hieratic papyrus[2] commemorate the successful wars in which he was engaged.[3] The most important of these was waged against the Hittites, called by the Egyptians the Kheta, and their allies, and was decided late in the fifth year of the king's reign. A powerful confederacy had been formed by the Hittites, the Khilibu, or people of Aleppo, the people of Karkamish, or Carchemish, and other tribes, some of which had been tributary to the crown of Egypt, and a great army collected to support their avowal of independence. The strongest of the confederates were the Kheta led by several chiefs. The king of Egypt marched against them, and the contending armies met in the plain of Ketesh, or Ashteroth-Karnaim, a strong city which formed the basis of the confederates' operations. The generals of the latter had made a skilful disposition of their forces. Having drawn up their infantry in a large and deep phalanx before Ashteroth-Karnaim, and behind the moat which surrounded that city, they posted their chariots on the other side of the moat. The chariot force had an open plain in which to manœuvre, while the infantry, placed on rising and wooded country, and protected by the moat, was ready to support the retreat of the rest of the army, or follow up its advance. The Egyptian chariots, led by the king and four of his sons, met and broke the charge of the Hittites; and notwithstanding that their infantry, having crossed the fosse by a bridge, endeavoured to maintain the day, they were put to the rout, and many of those who escaped the arrows of the chariot force and the swords of the infantry were drowned in attempting to recross the moat. Negotiations were in consequence commenced, which resulted in a treaty favourable to the king of Egypt. The war appears to have broken out again some years afterwards, for we find in an inscription of the temple of El-Karnak the record of peace having been concluded with certain chiefs of the Kheta, in the twenty-first year of the reign of Rameses II. The foreigners were compelled to pay tribute by this treaty, whence they must be supposed to have been previously worsted. Many other nations were subdued by Rameses II., but his chief exploit was the overthrow of the confederates. His great expeditions seem almost all to have been conducted in the earlier part of his reign, and its later portion appears to have been chiefly spent in advancing the welfare of the country by a promotion of the arts of peace.

War with the Hittites.

Menptah.

Menptah, the thirteenth legitimate son of Rameses II.,[4] reigned in his father's stead. Of his rule the records are few and of little importance; and a story is told by Manetho, who does not vouch for its accuracy, that then great troubles befel Egypt. He relates that, according to this account, the foreigners and unclean people who were in the country, having been sent to work in the quarries by order of the king, revolted, and, in alliance with a force of Shepherds of the race of those who had been previously expelled, called in by them from Palestine, effected the subjugation of Egypt, which they held for thirteen years, while the king was a fugitive in Ethiopia; and that at the end of that time he returned with Sethos his son, and drove them out with great slaughter. The leader of the rebels is said to have been Moses, and the people the Jews, but neither the time nor the circumstances are favourable to this view, which, nevertheless, is that of some eminent modern scholars. The monuments cannot be denied to afford corroboration to the story, by indicating that about this time there was intestine trouble in Egypt, and that at least one king ruled who was not afterwards regarded as legitimate by the Egyptians. The usurper was Siptah, who married Queen Ta-seser, a daughter of Rameses II.; and Amenmeses, whose place is not certainly known, probably succeeded him, being in that case likewise a usurper.

Siptah and Ta-seser. Amenmeses.

Twentieth Dynasty.

The head of the Twentieth Dynasty was Sethee II., who was probably the son of Menptah. His accession, and therefore the commencement of the dynasty, may be placed about B.C. 1220. The next date to this which may be regarded as certain is that of the beginning of the Twenty-second Dynasty, B.C. 1008 or 1009. The chronology of the intervening period is obscure, for Manetho assigns to the Twentieth Dynasty a duration of either 135 years, if we follow Africanus, or 178 or 172, if we take the authority of Eusebius. To the Twenty-first Dynasty, which was of Tanite kings, a duration of 130 years is assigned by both the chronologers above mentioned as that stated by Manetho. If these sums be at all near the truth, the two Dynasties must have ruled contemporaneously for upwards of forty or of eighty years. That such was the case is rendered probable by our finding at El-Karnak the names of only three of the latest kings, the fifth, sixth, and seventh, or last of the Twenty-first Dynasty, by whom a temple commenced under the Twentieth was continued.

Sethee II. Merer-ra. Rameses III.

The monuments tell us nothing important respecting the reigns of Sethee II., and of his successor Merer-ra: of the latter it can only be said that he evidently ruled but a short time, leaving the kingdom to his son Rameses III. With that sovereign the glories of the Theban line revived, and a series of great victories by land and sea raised Egypt to the place which it held under Rameses II., to whom alone he may be considered second as a warlike prince. In a stately temple, now called that of Medeenet-Haboo, which he raised on the western bank at Thebes, are sculptures and inscriptions commemorating the exploits of his reign, which are not, for the most part, elsewhere recorded. A small edifice, which was evidently a royal residence, and has been called his pavilion, and an extensive tomb in the Valley of the Tombs of the Kings, are the only other striking monuments of a reign which seems to have been much occupied in the prosecution of foreign wars. Of these, one of the most important, if not perhaps the most important, was that which he waged against "the Khairetana of the Sea," and the "Tokkaree," whom his fleet defeated in a sea-fight, which he beheld from the shore like Xerxes at Salamis. This sea-fight is the subject of one of the most remarkable battle-scenes which adorn the great temple of Medeenet-Haboo;[5] and it

[1] Both these events are recorded in the sculptures and inscriptions of the north wall of El-Karnak. Rosellini, *Monumenti Storici*, *loc. cit.*

Egypt.

is interesting to endeavour to ascertain who were the defeated peoples. The Shairetana, or Khairetana, are seen among the forces of Rameses II., as auxiliaries or mercenaries, distinguished for bravery, wearing crested helmets, and having short swords. Their name is identical, if we make allowance for the difference of the languages, with that of the Philistine tribe of "Cherethim," which furnished faithful mercenaries to King David. The same Khairetana we see in the army of Rameses III., in the expedition in which he overcame the Kharetana of the Sea and the Tokkaree. The Khairetana of the Sea would thus correspond to the Cretans, who are allowed to be of the same origin as the Cherethim, the former being the inhabitants of Crete, and perhaps of other islands, and the latter settled on the coast of Palestine. The identification of the Tokkaree does not seem so easy; yet it must be considered that the Carians are the only maritime nation having a name resembling that of the Tokkaree, who could, with any probability, have been associated with the Cretans, and that Herodotus relates, on the authority of the Cretans, that in the old days of the maritime power of Crete, the Carians inhabited the islands, and served in the ships of Minos, being "*by far the most famous of all nations in those times,*" and, moreover, bore another name, being called, he says, Leleges.[1] This war of Rameses III., as before remarked, is very agreeable with the Greek traditionary account, which tells of the great kings of Crete who held the empire of the sea until not long before the siege of Troy, that is, about the time of Rameses III., whom we may hence conclude to have been the cause of the overthrow of their maritime supremacy. Among the other nations whom Rameses III. conquered, were the Pelesatu, or Philistines, who have the same physiognomy and costume as the Tokkaree, thus indicating a common origin, the Rebu, a powerful people, and other uncertain races. Nine kings, all bearing the name of Rameses, succeeded Rameses III., but their rule was not (as far as we know) marked by great events, and scarcely any monuments but their tombs remain to commemorate it.

Rameses IV., V., VI., & VII.

Rameses IV., V., VI., and VII. were all sons of Rameses III.; and it is most probable that they supplanted one another, and thus weakened the country by their dissensions.

Rameses XII.

At the close of the reign of Rameses XII., the supreme power fell into the hands of a ruler of the Twenty-first Dynasty, three kings of which have left records at Thebes.

Twenty-first Dynasty. Amense Pahor. Piankh. Pisham.

The first of these was Amense Pahor, whom Manetho calls Osochor, and makes the fifth king of the Dynasty; the second, Piankh, who is, according to Manetho, Psinachês, the sixth king of the same line; and the third Pisham, Psusennês, the seventh and last. Pahor and Pisham are represented as priests, though receiving the titles of kings, a custom which was continued, but not so exclusively, under the next dynasty.

Twenty-second Dynasty.

Manetho calls the Twenty-second Dynasty, which next occupied the Egyptian throne, of Bubastite kings; and this statement receives some support from the circumstance, that the name of one of them has been found among the sculptured remains of the temples of Bubastis. These sovereigns cannot, however, have been of unmixed Egyptian origin, for Mr Birch has shown, from their names and those of princes of their family, that they must have been partly at least of Assyrian or Babylonian race.[2] Their policy, also, was rather that of those peoples than of the Egyptians, if we may judge from Sheshonk's war with Rehoboam; for

Sheshonk I., or Shishak.

Sheshonk I. is the Shishak mentioned in the Bible.[3] From this we are enabled to fix, with great probability, both the date of his accession, and the commencement of the dynasty of which he was the first king, as well as to establish a synchronism in the chronology of the kingdom of Egypt and that of Judah. The accession of Sheshonk I. may therefore be placed in the year B.C. 1008 or 1009, and his march against Jerusalem in that B.C. 988, his 21st or 22d year.

War with Rehoboam.

Among the sculptures of the great temple of El-Karnak is a list of nations and towns conquered by Sheshonk I., among which Champollion discovered the name of the kingdom of Judah, and of various cities, of which some appear to have been in the territories of Jeroboam I., to whom the king of Egypt seems therefore to have acted faithlessly.

Osorkon I.

Osorkon I., the next king, is supposed to have been the Zerah whom Asa king of Judah defeated in the year B.C. 962, or somewhat later;[4] but if Manetho's numbers have been rightly preserved, this king could not have been Zerah, though by that name might be intended a later Osorkon. Of the other kings of this dynasty, the monuments tell us scarcely more than the names. After having ruled 120 years, according to Africanus's version of Manetho's lists, it was succeeded by the Twenty-third Dynasty of Tanite kings, about B.C. 889.

Twenty-third Dynasty.

From this period until the accession of the Twenty-fifth Dynasty, the chronology and history is obscure. Of the Twenty-third Dynasty we know nothing of importance, and we cannot determine its duration. It is probable that the hieroglyphic names of some of its sovereigns occur on the monuments, but this is not certain.[5] With the end of the Twenty-second Dynasty, the fortune of the brightest period of Egyptian history deserted the Pharaohs; and except under the vigorous rule of the Ethiopians, and then of certain of the kings of the Twenty-sixth Dynasty, never returned. When Egypt had been united under a single head at the commencement of the Eighteenth Dynasty, those great expeditions soon began which made the Egyptian name famous in after ages. The countries lying to the east of Egypt, as far as the Euphrates, were overrun by the forces of the Pharaohs, and their inhabitants compelled to render allegiance, and make tributary presents, to those sovereigns. But no attempt seems to have been made to bring the strangers under Egyptian government, although alliances were entered into with some, in order to bind them in friendship with the conquering power. Notwithstanding their aversion to foreigners, there is abundant evidence that the Egyptians treated such allies with respect, unlike the Assyrians and Babylonians, who enslaved and transplanted the nations which they subdued. Constantly, however, the tributaries rose in revolt against the Egyptians, and caused many long and fierce struggles before they were reduced to their former condition; and they seem to have been supported in these contests by some great power seated on the Tigris or Euphrates. Ethiopia was, at least nearly as far as the junction of the White and Blue Niles, a province of Egypt, having the same religion and laws, and governed by a prince, called "the Prince of Kush." From the accession of Aah-mes, the head of the Eighteenth Dynasty, until the time of Rameses II., the power of Egypt gradually increased: under the latter king it attained its greatest height, and having apparently waned somewhat after his reign, it rose again through the vigour of Rameses III. Under the kings that followed him, the kingdom of Egypt fell into an insignificant condition; and in Solomon's time seems scarcely to have possessed anything in Syria. Sheshonk I., however, taking advantage of the divisions which followed the reign of Solomon, rendered the kingdom of Judah, and doubtless that of Israel also, tributary to him. But not long after his time, probably in consequence of the power of the Assyrian empire, Egypt again declined, and did not rise until the rule of the Ethiopians.

Twenty-fourth Dynasty. Bocchoris the Wise.

The Twenty-fourth Dynasty consisted of a single king, Bocchoris the Wise, a Saïte, the period of whose rule was 6 years, according to Africanus's version of Manetho, but

44 according to that of Eusebius. He was celebrated as a lawgiver. His reign was brought to a disastrous termination by Sabaco the Ethiopian, who, having taken him captive, burned him alive.

Twenty-fifth Dynasty.

Thus was established the Twenty-fifth Dynasty of Ethiopian kings, which can scarcely be considered a foreign line, since Ethiopia was so thoroughly Egyptian at that time; and the transfer of supreme power cannot, therefore, though effected by armed force, be regarded as very different from the earlier changes of one native dynasty for another.

Shebek I., or Sabaco.

The accession of Sabaco may be assigned to about the year B.C. 749. His hieroglyphic name, Shebek (I.), is found on some monuments of his reign, to which we may assign, with Eusebius, a duration of twelve years.

Shebek II., or Sebichus.

Sebichus, his son, succeeded him, and ruled, on the authority of Africanus, fourteen years. He likewise bears the name of Shebek (II.) on the monuments.

Treaty with Hoshea.

The most important event that we know of his reign is the treaty which he concluded (*cir.* B.C. 725) with Hoshea, the last king of Israel; who, nevertheless, was overpowered by Shalmaneser, the potent king of Assyria, soon afterwards. In the Bible he is called So or Sewa, after the manner in which Egyptian names are often abbreviated in Hebrew.

Tehrak or Tirhakah.

The last king of this dynasty—called by Manetho Tarcus or Taracus, in the Bible Tirhakah, and in the hieroglyphic inscriptions Tehrak—was one of the greatest sovereigns who ruled Egypt, insomuch that Megasthenes mentions him with Sesôstris as having carried his arms as far as Europe. Monuments in Egypt and Ethiopia, particularly at Gebel-Berkel, the ancient Napata, commemorate his piety and his success in war. He came to the throne *cir.* B.C. 723, and ruled twenty years, according to Eusebius' version of Manetho's Lists. In the year *cir.* B.C. 710 he advanced against Sennacherib to support Hezekiah, king of Judah. It does not appear whether he met the Assyrian army, but it seems probable that its miraculous destruction occurred before any engagement had been fought between the rival forces. Perhaps we may conclude that Tirhakah availed himself of this opportunity to restore the supremacy of Egypt west of the Euphrates.

Twenty-sixth Dynasty.

With the reign of Tirhakah the Twenty-fifth Dynasty closed; but, according to Eusebius, an Ethiopian, Ammerês, commenced the next line, the Twenty-sixth Dynasty of Saïte kings. The earlier part of that dynasty presents many difficulties, and it is not until the reign of Psammitichus, or Psametik I., that the history and chronology become clear.

Psametik I., or Psammitichus.

This king was, according to Manetho, either the fourth or fifth king of the dynasty, having succeeded Nechao I. Herodotus tells us that before his reign the country was ruled by a dodecarchy of which he was a member; and that, by the help of Ionian, Carian, and Phœnician mercenaries, he overthrew his colleagues, and rendered himself sole king of Egypt.[1] Psammitichus came to the throne in this manner, B.C. 664,[2] and reigned for fifty-four years. He was generally successful, and under him the arts began to show a marked revival. The sculptures of his time, and that of his successors in the same dynasty, are often not much inferior to those of the Nineteenth Dynasty, and far superior to those of the Twenty-second and Twenty-fifth. He did not forget the services of his mercenaries, especially the Greeks, and in addition encouraged their fellow-countrymen to trade with Egypt, and caused his subjects to be instructed in their language. In this manner, and by showing a preference to the Greek troops above the native Egyptian soldiers, he offended the latter, of whom a great force (said by Herodotus to have comprised 240,000 men) rebelled, and, notwithstanding the king's remonstrances, left their country, and established themselves in Ethiopia, far south of Egypt.[3] Even if the number stated by Herodotus be much exaggerated, this defection must have contributed to weaken Egypt, no less than the establishment of a mercenary force, which alienated the affections of the Egyptians, particularly the soldiery.

War in Palestine.

Psammitichus carried on a successful war in Palestine, and took Ashdod or Azotus, after a twenty-nine years' siege, or twenty-nine years after his army had first sat down before it.[4] Probably the town was held by an Assyrian garrison, for Tartan, the Assyrian general, had taken it from the Egyptians in the preceding century.[5] Towards the close of his reign Psammitichus averted an invasion of Egypt by the Scythians, who had gained possession of the kingdom of the Medes and the dominion of Asia. They advanced to Palestine on their way to Egypt, but Psammitichus, having met them, stayed their progress with presents and prayers.[6]

Neko.

His son—called in the inscriptions Neko, by Manetho Nechao II., and in the Bible Pharaoh-Nechoh—succeeded him in the year B.C. 610. His reign was marked by great events. In his first year he advanced into Palestine, marching along the sea-coast on his way to Carchemish on the Euphrates, and was met by Josiah, king of Judah, who, although he remonstrated, opposed his passage.

Battle between Neko and Josiah.

Their armies joined battle at Megiddo, called by Herodotus Magdolus, and Josiah was slain and his forces put to the rout. It is probable that Neko was successful in the object of his enterprise, and that he speedily returned to Egypt in triumph, having on his way back deposed Jehoahaz, Josiah's son, and set up Jehoiakim, his elder brother, in his stead. The expedition was apparently intended to strike a blow at the failing power of the Assyrians, whose capital soon after fell a prey to the combined forces of the Babylonians and Medes. The army, however, which was stationed on the Euphrates by Neko, met with a signal disaster three years subsequently, being routed by Nebuchadnezzar at Carchemish. The warlike king of Babylon pushed his success, and we read in the Bible, after the mention of Jehoiakim's death, that "the king of Egypt came not again any more out of his land; for the king of Babylon had taken from the river of Egypt unto the river Euphrates all that pertained to the king of Egypt."[7] But although warlike affairs occupied so much of his reign, Neko was not inattentive to the welfare of commerce, for he either commenced the canal from the Nile to the Red Sea, or attempted to clear the course of one previously dug; but in either case, the work was not completed.[8] He likewise maintained a fleet both in the Mediterranean and in the Red Sea; and Phœnicians, by his command, attempted and accomplished the circumnavigation of Africa.[9] He was an enlightened and wise prince, who encouraged foreigners without incurring the jealousy of the Egyptians, and whose dealings with neighbouring nations evince both moderation and policy.

Psametik II., or Psammis.

Psametik II., called by Herodotus Psammis, who succeeded his father B.C. 595, does not seem in his short reign of 6 years to have done anything worthy of record. Egypt, however, prospered under his rule, for the splendid tombs of his subjects, and those of his successors, show the wealth of the country from this time to its subjugation by Cambyses.

Uahphrah or Apries.

The next sovereign was Uahphrah, called Pharaoh-Hophra in the Bible, and by Herodotus Apries. He began to reign B.C. 589, and at first was eminently successful, for he entered Palestine and Phœnicia, taking Gaza and Sidon, and defeated the king of Tyre in a sea-fight.

Wars in Phœnicia and Palestine.

He also worsted the Cyprians.[10] Having thus restored the influence of Egypt, he succoured Zedekiah, the king of Judah, in his rebellion against Nebuchadnezzar, and when Jerusalem was

Egypt.

besieged by the Chaldeans the advance of his army compelled them to raise the siege.[1] The city nevertheless fell, and the power of Egypt in Palestine was crushed by the campaigns of Nebuchadnezzar. The fugitive Jews were kindly received by Pharaoh-Hophra,[2] and seem henceforward to have formed an important part of the population. At the fall of the kingdom of Israel many Hebrews had taken refuge in Egypt,[3] and this was not the only occasion on which their numbers were increased by other emigrants. Greater calamities than the loss of his influence to the east of Egypt befel Apries at a later time, for an army which he sent against the Greeks of Cyrene was cut to pieces, and a consequent military revolt placed the crown on the head of Amasis. Apries was deserted by all except the Ionian and Carian troops (30,000 in number), and a few Egyptians, but nevertheless he marched to meet the rebel. At Momemphis, near the lake Mareotis, a decisive battle was fought, and Apries was made prisoner by Amasis. At first the new king treated his captive with consideration, but afterwards yielding to the importunities of the people, who hated him, he gave him up to them, by whom he was strangled. Nevertheless he buried him royally.[4] Thus was fulfilled the prophecy spoken by Jeremiah: "I will give Pharaoh-Hophra, king of Egypt, into the hand of his enemies, and into the hand of them that seek his life."[5] There seems little doubt that at the time of this rebellion, and perhaps in conjunction with the advance of Amasis, Egypt was invaded and desolated by Nebuchadnezzar. It should be observed, however, that the remarkable prophecies of Ezekiel[6] may refer for the most part to the invasion by Cambyses.

Dethronement and death of Apries.

Aah-mes, or Amasis.

Amasis or Aah-mes came to the throne in the year B.C. 570, and ruled with great credit for nearly half a century. He endeavoured rather to consolidate the power of Egypt than to make extensive conquests, and thus he strengthened the country against its dangerous neighbours on the east. He was not regardless of the welfare of commerce, and the efficiency of his navies is shown by his having subjugated Cyprus and made it tributary. The Babylonian kingdom became so weak in his days, that he joined Nabonidus its king, and Crœsus the sovereign of Lydia, in an alliance to oppose Cyrus.[7] Nevertheless Babylon fell, and with it the remains of the great empire founded by Nebuchadnezzar, and the defeat of Crœsus followed the fall of his ally. Xenophon says that Crœsus was aided by a strong force of Egyptians, 120,000 in number, who in a great battle near Thybarra maintained themselves unbroken until Cyrus granted them honourable terms, and that he settled them in the cities of Larissa and Cyllene, on the coast of Asia Minor. From the manner in which this is narrated, and particularly from the evident appeal to the truth of the narrative on account of the cities being called those of the Egyptians, this seems to be, notwithstanding that it occurs in the *Cyropædia*, a genuine fragment of history. If so, we could well understand why Egypt was unable to offer a vigorous resistance to the Persian invader a few years later, since it would have thus been deprived of a great part of the army. Monuments were raised by Amasis throughout Egypt, of which some remains are yet to be seen, but his works were probably chiefly in Lower Egypt and at Saïs;[8] and hence there are no very remarkable ruins of his time, since the temples of Upper Egypt are the best preserved. Towards the close of his long reign Amasis found himself obliged to make great preparations to resist the threatened invasion of Cambyses, and at length died a little before that calamity befel his country. His son, Psammenitus, most probably the Psametik III. of the monuments, ascended the throne B.C. 525, and prepared to meet the advancing enemy. The king of Egypt, at the head of a native and Greek army, awaited the invader at Pelusium, which was long regarded as the key of the country, and is therefore called in the Bible "Sin, the strength of Egypt."[9] After an obstinate battle the Persians gained the day, and Cambyses advanced against Memphis. Thither he despatched a herald in a Mitylenian vessel; but the Egyptians, exasperated against the unjust invader, destroyed all on board. Cambyses then laid siege to the city, whose ancient fort, the White Wall, offered a protracted resistance, but at length fell into the hands of the invader, with Psammenitus the king. Thereupon Cambyses signalized his victory by characteristic acts of cruelty, rendered more odious by being partly enacted under a show of justice, and insulted the conquered king by the humiliation of his daughter to the rank of a poor slave, and the execution of his son as a low malefactor. Moved by shame rather than pity, he ordered the king's son to be spared when it was too late, but afterwards he was not able to refrain from the meanness of dragging forth and burning the mummy of Amasis[10] and that of his queen.[11] This queen was called Ankh-nes, her sarcophagus is now in the British Museum. Near it was discovered her burnt mummy. One cannot but regret that a desire to put a historical subject in a new light, which has worked so much mischief of late, should have raised up an apologist for a despot of whom no one good act stands recorded. The unhappy Psammenitus, having been led captive to Susa, was after a time put to death by drinking bull's blood, for having plotted against Cambyses. It is believed that Cambyses did not at first insult the Egyptian religion; indeed, there is evidence that he began by showing reverence, or a pretence of reverence, towards their gods; but having failed in his disastrous expeditions to Ethiopia and the Oasis of Jupiter Ammon, he became exasperated against the unfortunate Egyptians, and destroyed their temples and statues, and even wounded the bull Apis. After four years spent in Egypt, he left the country to quell the rebellion which had placed the Magi at the head of affairs, and shortly after perished from the effects of an accidental hurt.

Psammenitus.

Memphis taken by Cambyses.

Twenty-seventh Dynasty.

Darius Hystaspis.

Darius, the son of Hystaspes, having overthrown Smerdis, the Magus, early applied himself to the improvement of his great empire, and, whether from policy or goodness, strove to conciliate the various nations that composed it. During his visit to Egypt he gained the favour of the inhabitants,[12] and hieroglyphic inscriptions show that he caused the temples to be adorned with additional sculptures.[13] Notwithstanding, the Egyptians, unwilling to continue in servitude to a foreign power, revolted in the last year but one of his reign[14] (B.C. 486), but were reduced by Xerxes, his successor, in his second year (B.C. 484). Xerxes made his brother Achæmenes satrap of Egypt,[15] and the province remained quiet until his death, shortly after which Egypt again rose against the foreign rulers. Inaros, the son of Psammitichus, who was sovereign of some of the Libyans, and Amyrtæus, the Saïte, headed the insurrection. The Persians were driven out; and the insurgent leaders prepared to resist their return, by raising a native and mercenary force, and securing the assistance of the Athenians. Artaxerxes, as soon as he was firmly established on the throne, took measures towards regaining the lost province. An enormous army, said to have consisted of 400,000 men, and a fleet, were despatched under the command of Achæmenes, the late satrap. Inaros and Amyrtæus, instead of awaiting the advance of the Persians at the eastern frontier, wisely stationed their army in the western part of the Delta, where, if defeated, they could retire into Libya; and, if successful, they could place their enemies in

Egypt.

Battle of Papremis.

a most dangerous position. They joined battle near Papremis, the city of the Egyptian Mars, and the Persians were disastrously routed. The Athenians rendered great services, but the fortune of the day was decided by the valour of Inaros, who mortally wounded Achæmenes in single combat. The Athenians pursued the fugitive Persians by water, and blockaded them in the castle of Memphis.[1] Artaxerxes then despatched a second expedition, under Megabyzus, the son of Zopyrus and Artabazus, which, with the remains of the army of Achæmenes, appears to have exceeded in magnitude that unfortunate force. The Egyptians and Greeks advanced from Memphis, where they were still engaged in the siege of the castle, and were routed by the Persians in a battle, in which Inaros was wounded by Megabyzus. Having retreated to the island Prosopitis, the defeated forces maintained themselves for more than a year, until the Persians, having, partly at least, cut off the water which formed their best defence, forced them to capitulate. Inaros surrendered, on condition that his life should be spared—an engagement that was broken after he had been five years a captive, and he was crucified to gratify the revenge of Amytis, the mother of Achæmenes.[2] Amyrtæus, more fortunate than his colleague, escaped to the fens, where, in the island of Elbo, he defied all attempts of the Persians to reduce him. The warlike inhabitants of that part of Egypt warmly supported his cause, and their maritime position ensured them the succour of the Athenians.[3] Artaxerxes Longimanus granted some privileges to the conquered; and, in particular, made Thannyris, the son of Inaros, and Pausiris, the son of Amyrtæus, governors; thus in a manner causing them to succeed their fathers.[4] Early in the reign of Darius Nothus, after a long interval of rest, Egypt became again disturbed, and in his tenth year (B.C. 414) successfully asserted its independence. The details of the struggle are not known to us; all that can be said with certainty is that Amyrtæus, the Saïte, was proclaimed king, and was the first of a short series of Egyptian monarchs. Some maintain that this could not have been the same as he who fled to the marshes, and that such was the case cannot indeed be proved; yet there is nothing improbable in the supposition that he had never been subdued, especially as we hear of him as late as B.C. 450,[5] and sixty-four years of active life cannot be regarded as unparalleled in history.

Expedition of Megabyzus and Artabazus.

Artaxerxes Longimanus.

Darius Nothus.

Twenty-eighth Dynasty. Amyrtæus the Saïte. Twenty-ninth Dynasty.

The rule of Amyrtæus, the sole king of the Twenty-eighth Dynasty, does not seem to have been marked by events of importance. After having governed six years,[6] he was succeeded by the first king of the Twenty-ninth Dynasty. From this period until the final extinction of the Egyptian kingdom considerable difficulties beset our inquiries from the conflicting statements of historians. There will not be space in the present article to do more than indicate the most probable view of these questions, which do not affect the few great events of the period.[7] The first of the Mendesians (B.C. 408), Neferites or Nephreus, ruled tranquilly for six years, unmolested by the Persians, whom he opposed by aiding their enemies the Greeks. His name, written Nefâurut, is found in hieroglyphics. Achoris or Ackoris, the Hakori of the monuments (B.C. 402), governed for 13 years or more prosperously. He made great efforts to repel the advance of the Persians, and raised a force of mercenaries, of which he gave the command to the Athenian general, Chabrias.[8] Many sculptures attest the happiness of Egypt during this time of peace. Two kings, of whom nothing is known, followed Achoris, ruling for a year and four months; and with the second of them the dynasty came to a close, unless Eusebius be right in adding a third king, with a rule of one year.[9]

Nefâurut or Neferites.

Thirtieth Dynasty. Nekht-nebf, or Nectanebes I.

A new line, the Thirtieth Dynasty, of Sebennyte kings, succeeded to the supreme power. The first of this dynasty was Nectanebes I., called in the hieroglyphic inscriptions Nekht-nebf. His accession may be probably placed in the year B.C. 380, and he at once began to take vigorous measures to defend the kingdom against the Persians, who, under the powerful satrap Pharnabazus, were making formidable preparations to reduce it. The Athenians, with characteristic baseness, deserted his cause; and having sent for Chabrias from Egypt, despatched another eminent general, Iphicrates, to command the Greeks who served under the Persians. The king of Egypt, unaided by foreign troops, made the best disposition of his forces, and strengthened all assailable points. In the year B.C. 373, the Persians entered Egypt, led by Pharnabazus and Iphicrates, and finding Pelusium too strong for them, landed a force at the Mendesian mouth of the Nile, and captured the fort which defended it. But this success did not endure. The generals differed as to the plan of campaign, and Nectanebes worsted the enemy in several skirmishes and also in a battle. The difficulties of their position were increased by the overflow of the Nile. Iphicrates fled secretly thence by sea, and Pharnabazus was compelled to make a disgraceful retreat. This expedition is of no little importance, as it shows that the Egyptians, without foreign aid, on at least one occasion, both outmanœuvred and defeated a powerful Greek force, acting with a great Persian army; and serves to warn us against believing what the Greek historians, with the inordinate vanity of their nation, tell us on so many occasions, that the preservation of the Egyptian kingdom was owing to the bravery of their mercenary troops.[10] During the rest of the reign of Nectanebes Egypt remained unmolested, and the king repaired or beautified the temples.

Tachos or Teos.

Tachos, or Teos, succeeded Nectanebes I. in about the year B.C. 361. His first care was to take advantage of the distracted state of the Persian empire, and to raise an army and fleet by which to recover the influence of Egypt in Syria. The command of the fleet he gave to Chabrias, the Athenian, and that of the Greek mercenaries he intrusted to the celebrated Agesilaus, king of Sparta, while he himself was general-in-chief. Agesilaus was displeased that such a subordinate command had been bestowed upon him, and his enmity had no little share in the subsequent misfortunes of Tachos, which were as much owing to the friendly counsels of Chabrias. In order to raise money for the prosecution of the war, it became necessary to tax the inhabitants of Egypt heavily; and this, combined with the obnoxious character of the taxes, and the unfair extortion practised towards the priests, aroused the national discontent. When the king was already in Phœnicia, his brother Nectanebes, whom he had left to govern Egypt, plotted against him; and persuaded his own son, of the same name as himself, who was at the head of some forces in Syria, to try for the supreme power. Agesilaus was gained over by the usurper, and Chabrias was probably recalled by the Athenians, while the Egyptian forces deserted their king. Tachos could only flee, but his true character is shown by his immediately repairing to Artaxerxes Mnemon. The king of Persia, following the national policy, both received the fugitive well, and projected an expedition against Egypt under his command; but neither lived to see this design carried out, and Tachos is said to have died a victim to the consequences of the luxury of the Persian court.[11]

Rebellion, and dethronement of Tachos.

Nectanebes II.

In the meantime Nectanebes II. (B. C. 359) established

himself on the throne by the aid of Agesilaus. A Mendesian leader, whom Tachos had chosen for his successor, had raised a large though unwarlike force and proclaimed himself king; but after a sanguinary contest, the king of Sparta and Nectanebes put him to the rout, and Egypt was thus tranquillized.[1] These intestine struggles, however, had greatly contributed to the fall of Egypt, and may be partly, at least, ascribed to the turbulent mercenaries, whose policy must be condemned, even if we judge, as alone we can, from the partial accounts of their countrymen, the Greek historians, and those who drew their information from them. Had it not been for this civil war, although the expedition into Syria might have been unsuccessful, Egypt would have retained strength enough to withstand the Persians for the few years of weakness that preceded the fall of their empire. The early part of the reign of Nectanebes II. was prosperous, and he resisted with success the efforts which Artaxerxes, or Darius, Ochus, made to reconquer the country, and aided the Sidonians and other Phœnicians in throwing off the Persian yoke. The indolent king of Persia, roused by these disasters, collected a great army and fleet, took Sidon, subdued all Phœnicia, and reduced Cyprus. Mentor, the Rhodian, a leader of Greek mercenaries in the service of Nectanebes, who had been sent by him to aid the Phœnicians in their revolt, deserted to Ochus, and the route to Egypt lay open to the victorious army. Nectanebes prepared to make a vigorous resistance, by strengthening every defensible position and collecting an army of Egyptians, Libyans, and Greeks. Pelusium was successfully defended by a Greek garrison against the Thebans in the service of Ochus, until Nicostratus, the leader of his Argive mercenaries, having learnt by treachery a means of getting to the rear of the main Egyptian force under Nectanebes which was encamped near by, not only executed the manœuvre but maintained himself by defeating the Greek garrison of a fortress which sallied forth to oppose him. Then the king of Egypt, menaced by a superior army, partly in front of his position and partly in its rear, retreated with his whole field force to Memphis. The Greek garrison of Pelusium surrendered on terms to their fellow-countrymen, and the garrisons of the other strong places of Lower Egypt followed their example. Nectanebes, believing that he could not effectually oppose the invader, fled to Ethiopia by the river.[2] Thus Egypt again fell into the power of Persia in about the year B.C. 350, according to the best authorities. From that time until our own days, a period of twenty-two centuries, no native ruler has sat on the throne of Egypt, in striking fulfilment of the prophecy, "there shall be no more a prince of the land of Egypt."[3]

Invasion and subjugation of Egypt by Artaxerxes Ochus.

Causes of the decline and fall of Egyptian independence.

At this memorable point we must pause a moment to review the causes which led to the decline and ultimate fall of the native rulers of Egypt, after their power had been maintained, with little interruption, for more than 2300 years. The apparent chief cause of their ruin was the hostility of the three empires which successively governed the East. Under Rameses II. Egypt had attained its highest glory, under Rameses III. its position was maintained, but shortly after him its power suddenly failed. This is about the time at which Herodotus places the beginning of the Assyrian Empire. The kingdom of Egypt again acquired importance under Sheshonk I., a prince, partly at least, of Assyrian or Babylonian origin. His successors do not seem, for the most part, to have retained what he had acquired, and the country again lost its importance until the accession of the Ethiopian Dynasty. The princes of that line bringing with them a large and powerful territory, and being warlike and vigorous rulers, were enabled to check the advance of the Assyrians, and the third of them, Tirhakah, lived to the time of the first of those disasters which ruined the enemy, the miraculous destruction of Sennacherib's army. Had not a period of anarchy followed the Ethiopian rule, the ascendancy of Egypt might perhaps have been recovered. The establishment of Psammitichus was the beginning of an active line of native princes, who regained much of the former power of their crown, until Nebuchadnezzar, the head of the Babylonian empire, overthrew the army of Egypt, and destroyed its influence in Asia. Weakened by this contest, Egypt could not oppose a successful resistance to the pushing force of Persia, and fell almost at once into the hands of Cambyses. For nearly two centuries the history is but a record of the unequal struggle of the patriotic Egyptians against the overwhelming power of despotic Persia, and of the establishment of native princes, who latterly succeeded in maintaining the kingdom for almost seventy years against all the forces which could be brought against their enfeebled country. While such were the apparent causes of the downfall of this ancient power, others may be traced which, though less manifest to a superficial reader of history, seem mainly to have occasioned the success of Egypt's enemies. Until the time of Psammitichus the Egyptian soldiers had held the post of honour, but that king not only introduced Greek mercenaries into the army but treated them with especial favour, so that many of the native soldiers revolted and all became discontented. This course of conduct, which was mainly pursued by his successors, destroyed the old military system without substituting anything stable in its stead, and placed the defence of the kingdom in the hands of untrustworthy though brave men. The adoption of Greek manners by the great separated them from the sympathies and support of the lower classes, and at a time when unity alone could render the country strong enough to resist the aggressions of Persia, disunion everywhere prevailed.

Ochus, having gained possession of Egypt, signalized his success by outrages which it is needless here to relate. He did all in his power to insult the religious feelings of the unhappy Egyptians, and seems to have gone beyond Cambyses in his furious acts of barbarity. After a few years of Persian rule which are a blank in the history of Egypt, that country passed into the hands of Alexander the Great in the course of his conquest of the empire whereof it was a province.[5]

Greek kings, Alexander the Great.

From the time of Alexander commences a brighter period of Egyptian history, although its annals are those of Greek sovereigns and it witnessed the decay of Egyptian nationality. As the enemy and vanquisher of the Persians, Alexander was received in Egypt (B.C. 332) as a deliverer. The Persian governor had not forces sufficient to oppose him, and the cities opened their gates to him without even a show of resistance. Alexander visited Memphis, founded Alexandria, and went on pilgrimage to the oracle of Jupiter Ammon, manifesting on every occasion the greatest respect for the Egyptian religion. He then organized the govern-

[1] Plut., *Ages.* 38. [2] Diod. xvi. 40, *et seqq.* [3] Ezek. xxx., 13. [4] *Ancient Egyptians*, vol. i., pp. 212, 213.

[5] The chief ancient authorities for the history of Egypt under the Greek rule, from the conquest by Alexander, are the following: Ælian, Agatharchides, Ammianus Marcellinus, Appian, Arrian, Athenæus, Cæsar, and Hirtius; Cicero, Diodorus Siculus, Dion Cassius, Josephus, Justin, Livy, the first and second books of Maccabees, Pausanias, Pliny, Plutarch, Polybius, Porphyry, Quintus Curtius, Strabo, and Vitruvius. Scattered notices occur in the works of many other writers; and there are some historical inscriptions both in hieroglyphics and in Greek. The dates of accession of all the Ptolemies, except the first, have been taken from Ideler's Memoir *Uber die Reduction ägyptischer Dater aus den Zeiten der Ptolemäer* (Konigl. Akad. der Wissenschaften, Berlin, 1834). It should be remembered that it is meant that the accession fell within the Vague Year, commencing in the Julian Year specified: thus Ptolemy Philadelphus came to the throne in the year Nov. 285, Nov. 284, which was his first year. Reference has been also made for chronology to Lepsius's Memoir *Ueber einige Ergebnisse der ägyptischen Denkmäler für die Kenntniss der Ptolemäergeschichte* (Königl. Akad. der Wissenschaften, Berlin, 1852); and to Fynes Clinton's *Fasti Hellenici, &c.*

Egypt.

ment of the country, and departed to complete his subjugation of the Persian empire. For the remainder of his short reign, Egypt continued undisturbed, and though not well governed in his absence, enjoyed greater happiness and security than it had for a long antecedent period.

Ptolemy, governor in Egypt.

On the division of Alexander's empire, the government of Egypt fell to the share of Ptolemy, the son of Lagus, afterwards surnamed Soter, one of his favourite generals (B.C. 323). He was content for the present to govern in the name of Philip Arrhidæus or Aridæus, the feeble successor of Alexander, but did not neglect to get together an efficient army by which to maintain his position. Not long after he reached Egypt, the intestine troubles of Cyrene enabled him to annex it to his government, and about the same time he made another stroke of policy. The regent Perdiccas having despatched the body of Alexander from Babylon in order that it should be buried in Macedonia, Ptolemy met the important charge in Syria, and having gained to his side the general who escorted it, carried it to Memphis, until a tomb should be fit for its reception at Alexandria. Perdiccas, irritated at Ptolemy's having thus gained possession of Alexander's body, which was in this manner a source of war after it had ceased to contain the ambitious soul, marched against Egypt to punish the governor. After an encounter near Pelusium, in which Ptolemy had the advantage, Perdiccas outmanœuvred him by a night march towards Memphis, but was afterwards worsted in endeavouring to cross the Nile near that city. Many of the officers and men of the invading force now deserted to Ptolemy, and Perdiccas was assassinated by his officers. On this the army, with which were not only Philip Arrhidæus, but Alexander Ægus, the heir-presumptive to the throne, submitted to Ptolemy, who allowed it to depart to Macedonia, having appointed two guardians for the king and prince. The governor of Egypt pursuing his advantage, sent an army which (B.C. 320) reduced Phœnicia and Cœle-Syria; and probably it was at this time that he subdued Palestine. After a period of prosperity which was spent in adorning the new city of Alexandria with magnificent buildings, and settling the details of government with a view to the benefit of the country, Ptolemy was called upon to defend Egypt against the threatened invasion of Antigonus. Syria and Phœnicia were subjugated by the King of Asia (B.C. 315–314), but in the next year Ptolemy quelled an insurrection in Cyrene, and reduced Cyprus, in which he had before established a footing (B.C. 315). Having sailed from Cyprus he made a hasty inroad in which he inflicted some loss on Antigonus by taking cities on the coasts of northern Syria and Cilicia, and returned by sea to Alexandria. In the following year (B.C. 312) he advanced into Palestine and routed the forces of Demetrius, the son of Antigonus, at Gaza. Ptolemy thus regained Phœnicia; and Seleucus, who had been forced to flee to him, was restored to his government of Babylonia. Antigonus now marched against Ptolemy from Asia Minor, but the latter retired into Egypt, leaving his opponent the dangerous task of invading that country. After having failed in two attacks on Petra, Antigonus retreated, and a peace was concluded by which Ptolemy resigned Palestine to him (B.C. 311). The death of Alexander Ægus in the same year rendered Ptolemy altogether independent, although he did not assume the title of king, except on the Egyptian monuments, until B.C. 306. All his earlier sculptures bear the names of Philip Arrhidæus and Alexander Ægus, and the rest his own as king, none having been found with an inferior title; and it is therefore reasonable to conclude that he assumed in the hieroglyphic inscriptions the regal style immediately on the death of Alexander Ægus. Ptolemy soon after that event led an army against the territory of Antigonus, from whom he took many places in Syria and Caria, as well as the island of Cos; but he soon met with a signal reverse, for Demetrius engaging his fleet with an inferior force, off Salamis of Cyprus, almost annihilated it, Ptolemy himself escaping, though his son Leontiscus, as well as his brother Menelaus, thus fell into the enemy's hands. By this victory Cyprus came into the possession of Demetrius (B.C. 306). Elated by this success, Antigonus marched against Egypt with a large army, but was repulsed, and retired as before without having effected anything. Ptolemy then assumed the offensive, regained Cœle-Syria, and having united his forces with those of Lysimachus, Cassander, and Seleucus, joined battle at Ipsus with the forces of Antigonus and Pyrrhus. The latter were routed, and Antigonus, the most formidable opponent of Ptolemy, fell in the battle (B.C. 301). Having ruled in comparative peace for several years after this decisive victory, Ptolemy abdicated in favour of his son Philadelphus. His character was that of a prudent prince, generally merciful, of moderate ambition, and rarely guilty of political injustice. He warmly patronized literature, the sciences, and the fine arts, and showed an enlightened disposition by granting the Jews privileges which induced them to settle in great numbers at Alexandria.

War with Antigonus.

Ptolemy becomes king.

Ptolemy II., Philadelphus.

Ptolemy, surnamed Philadelphus (B.C. 285), inherited a kingdom that comprised not Egypt alone, but the south coast of Asia Minor, much of Syria, Palestine, and Cyprus, which had been recovered in B.C. 295. But after his father's death, which occurred B.C. 283, the first of those internecine struggles that disgrace the history of the Ptolemies broke out. The king's half-brother Magas, governor of Cyrene, revolted, and a war commenced, which after some years' continuance, was concluded by a treaty by which the daughter of Magas was to marry the son of Philadelphus, and to receive as a dowry the reversion of the possessions of her father, to whom she was sole heir. The death of Magas soon followed, and Cyrene was after a time restored to Egypt. Two other brothers of Philadelphus were subsequently put to death on different occasions by him on the ground of treason, of which one of them was certainly guilty. In the eleventh year of Philadelphus (B.C. 274) he sent an embassy to Rome to congratulate the republic on having repelled Pyrrhus, and to make a treaty; and an embassy from the People visited Egypt in return. Except the struggle with Magas, the rule of Philadelphus was almost unmarked by war. A contest with Antiochus II., king of Syria, ended in a treaty by which he took to wife Berenice the daughter of Philadelphus, who acquired no military renown. His long reign was rather distinguished by the erection or completion of magnificent buildings, and the advance of trade by the formation or repair of ports and stations, and the completion of the celebrated Pharos of Alexandria. He followed his father's example in patronizing men of letters, painters, sculptors, and the professors of science, and continued to favour the Jews. Nevertheless his private character cannot claim our admiration. Without being warlike, he was cruel, as towards his unfortunate brothers, and in the destruction of his Gaulish mercenaries, which, however politic, was most barbarous. He was luxurious and licentious in his manners, and seems to have owed his reputation of a great king rather to circumstances than to character. In no sense did he ever show himself heroic, and had his dominions been seriously endangered he would probably have left us little cause to respect him as a warrior or a statesman. Having ruled thirty-eight years he left his kingdom to his eldest son Ptolemy, surnamed Euergetes.

War with Magas.

Ptolemy III., Euergetes.

Ptolemy Euergetes was at the beginning of his reign (B.C. 247) called to take an active part by the trouble that befel his sister Berenice, the wife of Antiochus II., king of Syria. That sovereign having repudiated her, and taken back his first wife Laodice, was murdered by the latter, whose eldest son, Seleucus II., assumed the reins of power. By his, or rather his mother's, orders Berenice and her son were slain, before Euergetes could afford them succour.

Egypt.

Euergetes, however, avenged his sister in a brilliant expedition, by which he secured much of Syria and Asia Minor.

War with Seleucus II.

Afterwards Seleucus attacked Ptolemy, but was routed by his forces and those of his rebellious brother Antiochus Hierax. The latter, however, when fortune deserted him, sought refuge with Ptolemy, by whom he was kept in custody until he made his escape, and perished in his flight. The king of Egypt next conducted an expedition into Ethiopia, where he made extensive conquests. But notwithstanding these warlike actions, Ptolemy continued the generous patronage which his predecessors had extended to literature and science, and was especially attentive in improving the great temples of Egypt, or adding others to them. These, like all the edifices of the country, excepting those of Alexandria, were in the native style of architecture, which, although it had undergone some changes, was still that of the time of the Pharaohs. His temples and those of the other Ptolemies and Cæsars, excel many of the more ancient in size, though far inferior to them both in architectural beauty and in the execution of their sculptures. But they were not wholly raised by royal munificence, for large contributions from various cities, and even from foreign countries, aided in their construction. This circumstance, however, affords a strong evidence of the wealth of the subjects, and the freedom which they enjoyed.

Ptolemy IV., Philopator.

The reign of Ptolemy Philopator (B.C. 222), the eldest son and successor of Euergetes, commenced with an act of infamy, in the murder of his mother Berenice, his brother Magas, and his uncle Lysimachus.

War with Antiochus the Great.

Antiochus (III.) the Great soon attempted to break the power of Egypt in Syria, and reduced, by treachery and by force, the chief possessions of Ptolemy in that country, Phœnicia, and Palestine. Philopator having collected his forces, marched with 75,000 men against the enemy who now threatened Egypt. A battle, before which the soldiers of Ptolemy had been encouraged by the exhortations of Arsinoë the queen, was fought at Raphia, on the boundary, and the army of Antiochus was signally defeated (B.C. 217). A treaty was soon concluded, by which the king of Syria resigned his newly acquired territories.

Persecution of the Jews.

At Jerusalem, and after his return to Egypt, Ptolemy treated the Jews in a cruel manner, but afterwards stayed the persecution. Towards the close of his reign, he murdered Arsinoë, his sister and queen, and died, worn out by his vices, and unregretted by his subjects. With no good quality but a respect for letters and science, Philopator's character was marked by cruelty of the basest description, and by the greatest debauchery, and with him began the decline of the Greek kingdom of Egypt.

Ptolemy V., Epiphanes.

Ptolemy Epiphanes, the son of Philopator, was yet a child when he succeeded his father (B.C. 205). His reign was ushered in by a serious riot, in which the guilty minister and favourites of the late king fell victims to the vengeance of the people. This disturbance was followed by a graver danger, for Antiochus the Great, the king of Syria, and Philip IV. of Macedonia, formed an alliance in order to strip the young king of his possessions. Antiochus defeated the forces of Ptolemy, and speedily acquired Cœle-Syria and Phœnicia, as well as Judea, being supported by the Jews, who had hitherto been governed by the kings of Egypt. In this juncture those who ruled Egypt for the young king requested the Roman people to become his guardians, now that the very existence of the kingdom was threatened by such formidable enemies. The senate of Rome did not hesitate to accept a trust which promised so greatly to forward their ambitious views, and having recently overthrown Hannibal and crushed the power of Carthage, they felt able to support their client against the kings of Syria and Macedonia. Accordingly, they despatched messages to those sovereigns commanding them to abstain from attacking Ptolemy's dominions, and Marcus Lepidus, one of their ambassadors, became Ptolemy's guardian (*tutor regis*). Antiochus did not, however, desist from his enterprise; but being at length intimidated by a second warning of the displeasure of Rome, he entered into a treaty with Egypt, promising his daughter to the young king with the conquered territory as a marriage portion (B.C. 199). Before Epiphanes had attained his majority, the native Egyptians revolted, and were not reduced without a severe contest. They stood a siege in the town of Lycopolis, in the Delta, but the place was at length captured and the rebels subdued. In the year B.C. 196, the king was declared to be of age, and was crowned at Memphis.

Coronation of Ptolemy

To commemorate this event, as well as the privileges which had been granted by the king to the people, and particularly to the priesthood, the priests issued a decree, of which copies, carved on stone, were placed in the temples. One of these copies was fortunately discovered during the French occupation; and, bearing an inscription in Greek as well as in hieroglyphic and enchorial, it furnished European scholars with the means of interpreting the ancient characters of Egypt.

Rosetta Stone.

This tablet, which is now in the British Museum, bears the name of the "Rosetta Stone." Three years after his coronation, Cleopatra the daughter of Antiochus was married to Ptolemy, in fulfilment of the treaty previously concluded; but her promised marriage-portion of Judea, Cœle-Syria, and Phœnicia, was never given up by the king of Syria, who appears to have warred against Ptolemy as soon as he became his son-in-law. The king of Egypt made scarcely an exertion to recover his provinces, and at length fell a victim to poison, having reigned 24 years with indolence, incapacity, and cruelty.

Ptolemy VI., Philometor.

Ptolemy Philometor came to the throne of his father while yet a child (B.C. 181), and Egypt had again a minor for its sovereign. His mother Cleopatra, who was worthy of her father Antiochus the Great, governed the country for the young king, and maintained peace with her brothers Seleucus IV. and Antiochus (IV.) Epiphanes, kings of Syria. Ptolemy, after a few years, had the misfortune to lose his mother (B.C. 173), and then, through the headstrong policy of his ministers, to become involved in a war with the king of Syria. Antiochus soon marched against Egypt, routed the army of Ptolemy near Pelusium, took Memphis, and gained possession of the person of the king. His younger brother assumed the sovereignty at Alexandria, taking the name of Euergetes (II.), although he was usually known afterwards as Physcon, an appellation which he received on account of the bloated appearance which his intemperate habits had given him. Antiochus besieged the new king in Alexandria, but ambassadors from Rome having arrived during the siege compelled him to withdraw, retaining nothing but Pelusium, which he garrisoned with a strong force. He took away great spoil, so that the expedition cannot be regarded as having been wholly fruitless.

Ptolemy VI., Philometor, with VII., Physcon.

On the departure of the invader, Philometor and Euergetes made peace with one another, determining to rule jointly, and Cleopatra their sister, who had taken part with Euergetes, became the queen of Philometor (B.C. 169). In the following year (B.C. 168) the restless Antiochus again invaded the kingdom of his nephews, while his fleet subjugated Cyprus, but after penetrating into the heart of Egypt, was forced to retreat as before by the Roman ambassadors. Not long after this, strife again arose between the brothers, and Physcon having expelled Philometor, the latter carried his case before the Roman senate (B.C. 164). That council decided to restore Philometor to all his dominions excepting Cyrene, which they assigned to Physcon.

Ptolemy VI., Philometor alone.

In the ensuing year, however, Physcon went to Rome to request the senate to reconsider their decision, and grant him Cyprus which was now in his brother's hands, and to this petition they assented. Philometor, however, would not obey this order, and the Romans ultimately renounced their alliance with him, and commanded his ambassadors to leave the city in five days.

Egypt.

In the meantime Cyrene had risen against Physcon, and when he had subdued the people with difficulty, he again visited Rome to prosecute his cause (B.C. 154). Strengthened by a fresh decision of the senate, and otherwise aided by that body, Physcon, having raised an army, attempted to subdue Cyprus. His brother opposed him in person, leading the Egyptian forces, and having defeated him, forced him to surrender. Philometor most generously restored Cyrene to Physcon, and granted him other territories in the place of Cyprus: thus showing extraordinary clemency to which the history of the times scarcely affords a parallel, not less remarkable than the courage with which he refused to obey an unjust decision of the Roman senate.

War in Syria.

Philometor was next involved in war with Demetrius (I.) Soter, the king of Syria, and lent his support to Alexander (I.) Balas, who slew his adversary in battle. Having, however, discovered that Alexander was engaged in plotting against him, Philometor aided Demetrius (II.) Nicator in overthowing his father's enemy. In a decisive battle Ptolemy fell, having been carried by his horse into the midst of the enemy's forces, and thus terminated his long and chequered reign. If not a great king, he was certainly a good one, brave without cruelty, and merciful without weakness. Literature and science flourished under his protection, and magnificent temples were raised, or partly built, during his rule. Not the least remarkable proof of his enlightenment was the favour he showed the Jews, one event in whose history must not be passed by without notice. When Judea passed from the hands of the Ptolemies into those of the Seleucidæ, certain of the Jews continued to hold with the former, not forgetting the favours they had received from some of the kings of Egypt. Onias the high priest, and many others, having been expelled Jerusalem for this partiality, took refuge with the king of Egypt, who granted them land near Heliopolis, and permitted them to raise there a temple for their own worship. This contributed greatly to strengthen the Egyptian Jews as a party, and their importance did not cease until the temple was closed, not long after the destruction of that of Jerusalem.

Ptolemy VII., Physcon.

The reign of Physcon (B.C. 146) presents a dark contrast to that of his predecessor. He immediately took the crown from his brother's son and rightful successor, who had been proclaimed king by his mother Cleopatra. Having married her, Physcon put her son to death on the very day of the nuptials; and the greatest barbarity was shown towards his subjects. He next repudiated his wife, to marry his niece and stepdaughter, her younger daughter, Cleopatra Cocce. At length, the people, indignant at his cruelty and oppression, rose and forced the tyrant to take refuge in Cyprus

Cleopatra.

His repudiated queen, Cleopatra, was set up in his stead, and he revenged himself by murdering the son he had by her. The queen and the Egyptians sent an army to oppose one which Physcon had despatched against them, but their force was defeated on the eastern border of Egypt. Cleopatra sought aid of Demetrius II., king of Syria, who had married her eldest daughter; but that prince was unable effectually to assist her, being recalled after he had marched to Egypt by a revolt at Antioch. The queen had no resource but to flee to Syria, and Physcon recovered his throne

Ptolemy VII., Physcon, again.

(B.C. 127). He soon found occasion to punish Demetrius, by setting up an impostor, Alexander (II.) Zebina, who defeated and put to death the king of Syria. Ptolemy then made peace with Cleopatra, who came again to Egypt, and was honourably treated as the sovereign's sister and former queen. He then supported Antiochus Grypus in regaining his father's kingdom by the overthrow of Alexander. At last his long reign came to a close, to the great joy of his subjects; and Egypt was relieved from one who was perhaps the worst sovereign who ever ruled that unhappy country. He was ambitious, extremely cruel, intemperate, and debauched; and, though not an enemy to literature, could not pardon the political offences of its professors.

Ptolemy VIII., Lathyrus, and Cleopatra Cocce.

Ptolemy Lathyrus succeeded his father (B.C. 117), ruling jointly with his mother, the ambitious and cruel Cleopatra Cocce. The kingdom of Cyrene had been already given by Physcon, at his death, to his natural son Ptolemy Apion; and the island of Cyprus was given to Ptolemy Alexander, the younger brother of Lathyrus, who afterwards made it a monarchy. Cleopatra next expelled Lathyrus, because he would not be governed by her, and he took possession of the kingdom of Cyprus, while Alexander gained the throne of Egypt (B.C. 107).

Ptolemy IX., Alexander I., and Cleopatra Cocce.

Lathyrus was soon invited to support cities on the coast of Palestine against Alexander Jannæus, the king of Judea, and he conducted a successful campaign, in which he defeated the army of Jannæus in a sanguinary conflict. His mother Cleopatra, however, having taken vigorous measures, and accompanied one of her armies into Palestine, checked the successes of Lathyrus, and ultimately both sovereigns retired to their own dominions. The armies of Cleopatra were led by two Jewish generals, Chelcias and Ananias. Ptolemy Alexander, finding that he possessed nothing but the shadow of sovereignty, fled from Egypt. Cleopatra endeavoured to persuade him to return, while she laid a plot for his life, which he met with a counter-plot, and, as he arrived in Egypt, his mother was murdered (B.C. 90). After a brief rule the parricide was driven out by the Alexandrians, and at length slain in a combat with the fleet of Chæreas, an admiral of Lathyrus. Little need be said of the character of Cleopatra Cocce, and that of her younger son Alexander I., but that the former was as strong in character as the latter was weak, while both excelled in wickedness. The history, indeed, of the later Ptolemies and Seleucidæ presents an appalling picture of cruelty and vice, to which we can scarcely find a parallel.

Ptolemy IX., Lathyrus, restored.

Ptolemy Lathyrus was recalled from Cyprus to fill the throne left vacant at his brother's flight (B.C. 89). The most memorable event of this part of his reign was the revolt of Upper Egypt. The misrule of the preceding sovereigns had aroused the natives to make a fresh effort for their independence. Ptolemy marched against them, defeated them in battle, and laid siege to the ancient city of Thebes, their stronghold. The insurgents offered a desperate resistance, and for three years was the city beleaguered in vain. At last it was taken, and the bravery of its defenders punished by its being sacked and destroyed. Even the temples were not spared; and while we deplore the damage that they sustained during the siege and at the razing of the town, we are not displeased to find such records of a noble resistance in structures commemorating the ancient glories of the race. Nothing else worthy of notice marked the later years of Lathyrus, who left the reputation of an able and warlike, but cruel king.

Cleopatra or Berenice.

The daughter of Lathyrus, and widow of his brother Alexander, Cleopatra or Berenice, succeeded her father (B.C. 82); but her rule was of very short duration, for her step-

Ptolemy X., Alexander II.

son, Ptolemy Alexander II., was sent from Rome by Sylla to assume the crown and marry Cleopatra. On the day of the nuptials he murdered the unhappy queen, after she had governed about half-a-year. This crime aroused the indignation of the king's guards, who deservedly punished it with death. It is most probable that this was the Ptolemy who left his kingdom to the Roman people, whose patronage he had enjoyed, by his will; but motives of policy prevented their grasping at once at the prize.

Ptolemy XI., Auletes.

Ptolemy Neus Dionysus, commonly known by the surname which was given him of Auletes, or the Flute-player, next ascended the throne (B.C. 81). The first part of his rule was passed in tranquillity, but he earned the dislike of his subjects by a vicious and disorderly life, until, in the twenty fourth year of his reign, he found himself obliged to flee from Egypt (B.C. 58). The immediate cause was perhaps

Egypt.

the seizure of Cyprus by the Romans, who dispossessed his brother Ptolemy, king of that island, and made his dominions a Roman province. The Egyptians, incensed at this exercise of grasping ambition, pressed Auletes to demand the island, which had been ruled by the preceding kings of Egypt or a prince of the family, and, in the event of a denial, to declare war against the Romans. On the king's refusal to adopt this line of policy, a revolt was excited, and he fled to Rome from Alexandria. Immediately that the king had left, his wife and daughter, Cleopatra Tryphæna and Berenice, were chosen to succeed him as joint sovereigns. After having ruled for a year, Cleopatra died, and Berenice married Seleucus, surnamed Cybiosactes, or the Scullion, the son of Antiochus Grypus. He was soon murdered, by his wife's orders; and she took a second husband, Archelaus, who pretended to be a son of Mithradates[1] the Great, king of Pontus. Having reigned two years more, she lost her power and her life on her father's restoration, which thus happened: Auletes had previously learned by experience that the great Roman aristocrats were not insensible to the effects of bribery, and on reaching Rome he occupied himself in securing by this means the interest of the chief senators. Although he was thus far successful, various difficulties arose which prevented his gaining the assistance of a Roman army until his exile had lasted for three years, which he spent at Rome and Ephesus. He then went to Syria, being strongly recommended by Pompey to the proconsul Gabinius, and supported his proposals with an enormous bribe of ten thousand talents. Gabinius, taking the king with him, marched against Egypt, defeated the army which opposed his passage, subjugated the country, and restored Auletes (B.C. 55), who at once put his daughter to death. In this expedition, Mark Antony served as an officer of Gabinius, and thus visited the country which was to witness his future greatness and fall. From this time Ptolemy Auletes ruled without opposition until his death, which occurred in the year B.C. 51. He left his kingdom to the joint government of his eldest children, Cleopatra and Ptolemy, whose rights he trusted to the protection of the Roman people. Pothinus, the governor of Egypt, did not, however, scruple to set aside Cleopatra, and make Ptolemy sole sovereign under his tutelage. Cleopatra, although but about twenty years of age, acted at once with a vigour that was worthy of the better times of the Ptolemies; and having fled into Syria, succeeded in bringing together an army, with which she advanced to Egypt in the second or third year after her father's death. Ptolemy's army was sent to Pelusium to oppose her entrance, and, at this important juncture, Pompey, fleeing from the fatal field of Pharsalia, landed on the Egyptian shore, and put himself in the hands of Ptolemy's ministers. Forgetful of the benefits which Auletes had received from the great Roman in his exile, and in defiance of their plighted words, they murdered the guest—affording by this crime one of the many instances of the utterly corrupt state of the ruling class at that period. Cæsar had lost no time in pursuing his vanquished rival; and not long after, disembarked with a small but efficient force of four thousand men at Alexandria. Being now rid of his fears of Pompey, he set himself to arrange the affairs of Egypt. The army led by Achillas, which had been sent against Cleopatra, returned to Alexandria, and closely invested that part of the city which was held by Cæsar's force. A sanguinary contest ensued, in the course of which the famous Library perished by fire, and thus the learning which had formed the chief ornament of the capital received a fatal blow. Notwithstanding the smallness of his army, Cæsar was able to maintain his position, and was strengthened by the arrival of Cleopatra, who reached Alexandria in disguise, having left her army near Pelusium. The attractions of the young queen had at once engaged Cæsar in her favour, and he had determined to make her sole ruler, to the prejudice of her brother. Ptolemy, feeling himself to be unjustly used, determined to regain the throne by arms; and a war ensued, which lasted for several months, until, on the arrival of reinforcements to Cæsar's army, the young king was vanquished, and perished by drowning in an engagement, probably near the sea-coast (B.C. 48 or 47). Not long after this, Cæsar left Egypt, having established the power of Cleopatra, with whom he associated in the government her young brother Ptolemy, who was then betrothed to her at a tender age. Egypt was so thoroughly reduced to order by these measures that Cleopatra did not fear to leave the country, and reside for a time at Rome with Cæsar, whence she returned subsequently to his murder. Shortly afterwards, it is believed—but this is not certain—she put young Ptolemy, her brother and nominal husband, to death, fearing that he would become too powerful for her. Cleopatra did not take any decided part in the struggle for power which followed the murder of Cæsar, and on the fall of Brutus and Cassius, Antony summoned her to Tarsus, to explain this ambiguous course (B.C. 41). Mark Antony was as easily vanquished as Cæsar had been by the captivating queen of Egypt. Thenceforward Antony and Cleopatra ruled together, and the events of this period belong rather to Roman history than to Egyptian. The chief part of this time, in which a great empire might have been consolidated, was spent by Antony in pleasure and vice; and by degrees he lost his influence over his fellow-countrymen, which passed into the hands of the politic Octavianus. Defeated in the one naval fight at Actium (B.C. 31), Antony was forsaken by his former courage, and fled with Cleopatra to Egypt. When Octavianus invaded the country, they offered no adequate resistance; and both, in despair, perished by their own hands—Antony, partly because Cleopatra had given out that she was dead, Cleopatra, partly because Antony had perished; but both, also, to escape that treatment which they knew they would receive at the hands of their heartless conqueror. So ended the great Dynasty of the Lagidæ, after having endured for nearly three hundred years. Cleopatra was not unworthy to be the last of that great line, whose virtues and faults she combined in a high degree. In person she does not seem to have been very beautiful, but rather excelling in grace of manner and every winning art. Busts and coins would lead us to the former supposition, and the latter would naturally follow. Her knowledge was extensive, and she was acquainted with many languages. Literature and science met with her encouragement; and she endeavoured to restore the Library of Alexandria, by having transported thither the rival collection of the kings of Pergamus. Ambition was her ruling passion, and to it she sacrificed her maidenly honour and the ties of relationship. Although she was famous for the luxury of her court, it is most probable that she maintained that manner of life rather to govern those who governed the world, and to display her magnificence, than for pleasure's sake. The princess who ruled, not alone the affections, but the fierce wills of Julius Cæsar and Mark Antony; who upheld a tottering monarchy, and made those who subdued it raise it to an empire; who fell at last through the strange weakness of Antony, and the treachery of his followers, and feared not to die by her own hand, must take rank among the greatest of historical characters. The Ro-

[1] It is much to be regretted that the carelessness of ancient historians, or their copyists, should have introduced a false orthography of this name, which is now almost always written Mithridates. The inscriptions of ancient coins, for example, of the silver tetradrachms of Mithradates the Great, some of which bear a wonderfully fine portrait of this king, as well as the etymology of the name, warrant the adoption of Mithradates as the true form.

mans, who are ever ungenerous to their enemies, paint her character in dark colours, hating her because she governed their fairest provinces and their most renowned generals. But if we remember in what court she was trained, and consider the manners of that time and country; if we extend to her faults that indulgence that many have granted to those of Cæsar and Antony; if we recollect her love of learning, and have paced the stately temples which she raised, we shall acknowledge her one of the greatest sovereigns of the ancient world, not inferior to Catherine of Russia, who, in a Christian country and an enlightened age, committed the same crimes, but met not with the same condemnation. Her death itself, praiseworthy according to the religion of those days, was

> ———"well done, and fitting for a princess

Egypt under the Romans. Augustus.

When Egypt thus fell into the power of Augustus (B.C. 30), its condition may be likened to what it was when Alexander acquired possession of the country. The internecine wars and misrule of the later Ptolemies had gradually lessened the good which their predecessors of the same line had effected. Taxation had increased, commerce had dwindled; and in one particular the future of Egypt was yet darker, for the three centuries of Greek rule had tended to weaken Egyptian nationality, by making the natives either Greeks or slaves. If Greeks, they scarcely looked to Egypt as their country; if slaves, they had no higher hopes than for a mild ruler. The system of government which Augustus introduced was not one tending to better the province and its inhabitants. It seems to have been framed so as to crush national feeling among either the Egyptians or the Greeks settled in Egypt, and to prevent the Roman prefect who governed the country from making use of its resources to render himself independent; and, at the same time, so as to carry out these objects without, as far as possible, diminishing the productiveness of the province. The prefecture and the most important of the inferior offices were given to Romans alone, the rest were held by Greeks or Egyptians. The country was garrisoned and protected by two legions, part of which was stationed beyond the frontiers, and by a small force of German horse. The new rulers at first imitated their predecessors, in causing temples to be built, or in adding to those which were already raised; but after the second century of Roman government, these and other public edifices were comparatively neglected.[2]

Ælius Gallus, the prefect.

Ælius Gallus, a prefect of Egypt under Augustus, made an unfruitful expedition against Arabia Felix, but was afterwards more fortunate in punishing an inroad of the Ethiopians. Gallus not only defeated the invaders, but in his pursuit penetrated to Napata, the capital of Candace, their queen, and captured that city. From this time no events of interest mark the history of the province until the reign of Vespasian.

Vespasian.

Under him the Jews of Egypt met with several persecutions. They had previously been embroiled with the Greeks at Alexandria, and had been on one occasion cruelly treated for refusing to worship the statue of Caligula. But in the reign of Vespasian their temple, which Onias had founded, was closed, and they did not escape some share of the treatment which their fellow-countrymen in Judea received at the hands of the Romans.

Trajan.

In Trajan's reign they revolted (A.D. 115-117), and were not subdued until much blood had been shed. Hitherto they had held equal privileges with the Greek inhabitants, but at this period they forfeited these advantages, and were afterwards considered to be no better than the native Egyptians. In the next reign the Emperor Hadrian, during his inspection of the provinces, visited Egypt (A.D. 130), as well as on a subsequent occasion (A.D. 134).

Hadrian visits Egypt.

He endeavoured to benefit the people by (as he himself says) renewing their old privileges and granting new ones.

Antoninus Pius. A Sothic Cycle commences.

In the reign of Antoninus Pius a Sothic Cycle commenced in the year A.D. 138, an event which is commemorated on the coins of Alexandria. The preceding great period had commenced B.C. 1322, when the kingdom of the Pharaohs was, under Sethee I., in its most prosperous state; and now, when the unchanged cycle again began its course, how changed was Egypt! The country was a province ruled by a race whose traditionary history ascends only to a time after Egypt had already declined, the people were enslaved, the religion was on its wane, the priestly learning well nigh gone, the arts and sciences forgotten by them who had taught them to the western world. The few who knew of the earlier cycle must have watched with a melancholy interest the birth of the present one, fearing that it would live to witness the ruin of all they revered, and the fulfilment of that prediction which has come down to us under the name of Hermes Trismegistus, describing the state of Egypt for many centuries past with a painful truthfulness. Another Sothic cycle began A.D. 1598, not long after the independence of Egypt had received its last blow, and that crushing despotism of Turkey had commenced which was to destroy not only the memory of the past and the happiness of the present, but the hope for the future.

Rebellion in reign of Marcus Aurelius.

After various troubles, principally occasioned by the turbulence of the Alexandrians and the inroads of barbarous tribes, a serious rebellion distinguished the reign of Marcus Aurelius. The prefect of Egypt, Avidius Cassius, having suppressed a serious revolt, assumed the purple (A.D. 175), and was acknowledged as emperor by the armies of Syria and Egypt. On the approach of Marcus Aurelius, the usurper was slain by his adherents, and his party at once gave way, and were treated by the emperor with the utmost clemency.

Pescennius Niger.

Not many years afterwards, Pescennius Niger, who commanded the forces in Egypt, was proclaimed emperor in the place of the murdered Pertinax (A.D. 193); but, after a short rule, was overthrown by his rival Severus.

Septimius Severus.

The new emperor, perhaps because Niger was chosen by the Roman army rather than by the Egyptian people, did not use severity towards the province; on the contrary, when he visited it he bestowed great privileges upon the Alexandrians.

The Christians persecuted.

Nevertheless, his reign was marked by the first persecution of the Christians of Egypt, the prelude to many others. Although we cannot be sure when Christianity was introduced into Egypt, it early obtained a numerous body of followers there, and by this period included among their number many of the learned and the powerful. The schools of Alexandria had gradually declined from the days of the earlier Ptolemies, until they had become the homes of sophistry and magic arts; but now the doctrines of the new religion raised a fresh class of learned men, and the very pagans gained knowledge by endeavouring to oppose them.

Caracalla.

In the next reign a great calamity befel the Alexandrians, for Caracalla, in revenge for an affront which they had offered him, signalized his visit by a wholesale massacre of the unfortunate citizens, and by other acts of tyranny.

Trajanus Decius.

Another persecution of the Christians occurred in the reign of Trajanus Decius (A.D. 250); and about the same period commenced those theological disputes which henceforward form the most remarkable subjects of the history of Egypt until the Muslim conquest. During

[1] *Antony and Cleopatra*, act 5, scene 2.

[2] The materials for the history of Egypt under the Romans are principally found in the works of the following writers: Abu'l Faraj (or Abulfaragius), Ammianus Marcellinus, St Athanasius, Cassiodorus, Epiphanius, Dion Cassius, Eusebius, Eutychius, Herodian, St Jerome, Josephus, Lampridius, Leontius, Lucian, Nicephorus, Philo Judæus, Pliny, Plutarch, Porphyry, Procopius, Ptolemy, Rufinus, Seneca, Socrates the ecclesiastical historian, Sozomen, Spartianus, Strabo, Suetonius, Tacitus, Tertullian, Theodoret, Theophanes, Flavius Vopiscus, and Zosimus, and in the *Chronicon Alexandrinum*.

Egypt.

Æmilianus.

the troublous reign of Gallienus, Æmilianus was proclaimed emperor by the troops at Alexandria; but after governing a short time with decision and activity, he was defeated and taken prisoner by the general of the forces of Gallienus. At the close of his reign, Zenobia, the ambitious queen of Palmyra, attempted to wrest Egypt from the Romans; but, although successful in a battle with the emperor's forces, her army was unable to gain possession of the country. Two years subsequently, Zenobia reduced Egypt to her rule, a little before her overthrow by Aurelian. Not long afterwards Egypt rose against Aurelian, and Firmus, who seems to have been elevated to the dangerous dignity by the native population, was proclaimed emperor (A.D. 272). In order to subdue this powerful rival, Aurelian led an army against him; and succeeded in accomplishing his overthrow. Probus, who had governed Egypt for Aurelian and Tacitus, was chosen by the troops in Egypt, at the death of the latter sovereign, as his successor, and speedily acquired the rest of the empire.

Zenobia conquers Egypt.

The reign of Diocletian ushers in a more prosperous period of Roman history, when stern military despots knew how to curb the turbulent soldiery, who had been so long used to make and unmake kings; but to Egypt the time of his rule was one of great misfortunes, marked by a serious rebellion and a terrible persecution. Early in his reign (A.D. 288) Egypt revolted, and Achilles was raised to the purple. A long struggle ensued, which was only terminated by the arrival of Diocletian, who took the strongholds of the rebels, and reduced the country, or at least the greater part of it, to obedience (A.D. 292). The chief of the insurgents, however, was not taken, and having again raised his standard after the emperor's departure, he gained possession of Alexandria. The revolt was of so important a character, that Diocletian returned to Egypt to quell it. Achilles having shut himself up in Alexandria, made a determined resistance; but at length the city was taken, and with his life he paid the penalty of his daring (A.D. 297). Several years after this, the cruel emperor published that famous edict against the Christians (A.D. 303), which caused one of the hottest of the persecutions that tried the faith and awakened the zeal of the early church. The events of that time of suffering belong to ecclesiastical history, but it should be mentioned here that from the commencement of this reign (A.D. 284), which they call the Æra of the Martyrs, the Copts reckon their chronology, looking back to this as the heroic period of the church in Egypt. Their traditions and history alike are full of narratives of the constancy of the holy men and women, of the monks and virgins, who suffered at this time, and of whom the world was not worthy. Would that the Coptic church—which has seldom fallen short of the early days of Christianity in steadfast adherence to its profession amidst many persecutions—had not lost the spiritual character of the primitive church. With the accession of the politic Constantine (A.D. 323) the persecution, which had continued until then with greater or less virulence, came to a close, and the Christians recovered their liberty, and were able even to hold themselves above the pagans. Then commenced the great Arian controversy, which was the means of bringing forward the zeal and abilities of St Athanasius, the greatest archbishop of Alexandria. Arius, who was a presbyter of the church of Alexandria, having first broached those doctrines which have since been known by his name, a controversy arose, which was referred to Constantine. The emperor wrote such a letter as one would write who adopted Christianity as a matter of expediency, and desired to use the church as a political weapon. He desired the disputants to cease from those questions, as though men of strong will or firm belief could thus keep their convictions to themselves, and refrain from propagating their opinions or defending their faith. The contest continued, and it became necessary to call a general council at Nicæa

Revolt of Achilles.

Edict against the Christians.

Constantine the Great.

The Arian controversy.

Council of Nicæa

(A.D. 325), where Arius and his party were condemned. Subsequently, however, Arius appealed to Constantine, who commanded St Athanasius (now archbishop of Alexandria) to re-admit him into the church. St Athanasius refused, and after some years was, by the emperor's influence, driven from his see and from Egypt. He returned after the death of Constantine (A.D. 338), being supported by Constantine II., but was afterwards again deposed by a council held by Constantius II. (A.D. 341). The feelings of the orthodox and the remonstrances of Constans induced Constantius to restore St Athanasius to the archiepiscopate (A.D. 349); but when that emperor had become monarch of all his father's dominions he determined to remove the obnoxious churchman, and forced him, after a manly resistance, to escape from a post where he could no longer continue without the prospect of being dragged thence by the soldiery. An Arian, George, was after a while forcibly installed in the vacant chair, and the orthodox experienced a cruel persecution. On the accession of Julian the Apostate, George fell a victim to the fury of a pagan mob, and St Athanasius returned to his see; but by an order of the emperor he was again banished. During the reign of Julian, the Christians of Egypt, although not actually persecuted, were treated with contempt, and all was done that could tend to weaken them and strengthen the pagan party. By Jovian St Athanasius was again recalled (A.D. 363), but in the following reign (that of Valens) he was once more deposed; but the emperor, probably yielding to the strong feeling of the people, who would have taken up arms to restore him, soon recalled him. At length he died in peace among his flock, and his memory is yet revered throughout Christendom, as that of one of the stoutest upholders of the faith in a time of great troubles. His firmness in refusing to obey the emperors against his conscience, his moderation in abstaining from maintaining himself by raising the people, his care for his flock whether among them or absent, and his patience when persecuted, all claim our admiration, and show us how it was that the Egyptians supported him with such an entire devotion. The emperor Valens appointed an Arian, Lucius, in his stead, and the orthodox again suffered a persecution at the hands of their opponents, supported by the authority of the state.

Egypt.

Julian the Apostate.

Death and character of St Athanasius

By Theodosius I. orthodoxy was not only restored, but paganism was abolished. The enforcement of the latter part of his celebrated edict caused disturbances at Alexandria, and the Christians seem to have exercised their power with somewhat of cruelty; but before we condemn them, we should remember what abominations had been practised under the name of religion by the Greco-Egyptians. At this time, however, it is very clear that much had already been done to corrupt the simplicity of the church in Egypt, and in particular monasticism had been carried to an extraordinary extreme. This is not the place in which to combat that institution, but it may be asserted, without fear of controversy, that when a large proportion of the population of a country take the monastic vows, and, fleeing from active life, establish themselves not as solitaries, but in settlements whether in the desert or in tracts otherwise uninhabited, we may fairly question the healthy condition of the church, and apprehend the injury to the state which has arisen from such practices in Tartary and China as well as other countries. During the weak reign of Arcadius, Egypt was agitated by religious strife, between those who held anthropomorphite doctrines, and the smaller party which maintained the opinions of Origen. In the next reign, that of Theodosius II., the archbishop Cyril and his adherents disgraced themselves by persecutions of the Jews and pagans. The former were expelled from Alexandria, and the latter maltreated, especially Hypatia the daughter of Theon, distinguished for her beauty as well as for her learning, whom the clergy inhumanly murdered, with, it

Theodosius the Great.

Monasticism.

Theodosius II. Cyril.

Egypt.

is said, Cyril's connivance or approval. To such lengths was intolerance carried by ascetic zeal.

Marcian. Separation of the Coptic church.

Under the Emperor Marcian, the serious religious dispute which caused the separation of the Coptic church attained its height. Dioscurus, the archbishop of Alexandria, supported a priest of the name of Eutyches, who had been excommunicated for asserting the Monophysite doctrine of the Egyptians. Indignant at this interference, the Greek bishops called an œcumenical council at Chalcedon, and not only condemned the Monophysites, but put Dioscurus and those who held the same opinions beyond the pale of the church (A.D. 451). A new archbishop of Alexandria, Proterius, was installed by force of arms and not without a vigorous resistance, but after the emperor's death he was murdered by the people of Alexandria. The Monophysites were, however, again put down, and for a time the orthodox party remained in undisturbed possession of the supreme authority. The Emperor Basiliscus, himself a Monophysite, restored the Egyptian party to power, but on his death, two years afterwards, troubles recommenced; after a time, however, the Alexandrians triumphed, and Zeno granted them the right of choosing their own patriarch.

Council of Chalcedon.

Basiliscus.

Zeno.

Byzantine empire.

The commencement of the Byzantine empire, which is rather a chronological epoch than a turning-point in history, caused no changes in the condition of Egypt. The first sovereign, Anastasius, did not disturb the ecclesiastical system which he found in force, and the Egyptian or Jacobite party were unmolested during his reign. Although thus exempt from ecclesiastical troubles of any magnitude, Egypt was a prey to the forces of an invader. The Persians (A.D. 501) ravaged the country and menaced Alexandria, but being manfully opposed, retired at length, leaving cruel traces of their pillage. In the reign of Justin I., troubles in the church again arose, the emperor desiring to establish an orthodox archbishop, and the strife thus kindled continued through his reign. Justinian I., although he showed himself in many respects an able sovereign, had not the wisdom to see that a tyrannical policy in religious matters could only tend to estrange his Egyptian subjects. Accordingly he appointed an orthodox or Melchite bishop, who was followed by another; but the latter was expelled by the Alexandrians. Upon this the emperor sent Apollinarius as patriarch and prefect, with an armed force by which to establish himself. By opposing violence to violence he succeeded in putting down his opponents, but his conduct would not have been justifiable in a governor and was atrocious in a churchman. The reign of Justinian I. is further marked by the final closing of the philosophic schools throughout the empire, and the departure of the last of that long line of learned men to whose industry we owe so much.

Anastasius.

Persian invasion.

Justin I.

Justinian I.

Closing of the philosophic schools.

The first event of great importance after this was the invasion and subjugation of Egypt by the forces of Chosroes, or Khusroo Parvez, in the reign of Heraclius. In the course of those brilliant campaigns by which the king of Persia stripped Heraclius of all his eastern provinces as far as the Bosphorus itself, one of his armies entered Egypt, and reduced the country without opposition[1] (A.D. 616). This success was owing no less to the enmity of the Jacobites for the Melchites than to the weakness of the empire, as was the subsequent Muslim conquest. The Persians had the good sense to perceive that their rule would be strengthened by favouring the native party, and, accordingly they raised a Jacobite, Benjamin, to the patriarchate, from the office of bishop of the Alexandrian Monophysites. After a few years of peaceful government, reverses overtook the Persians, and Egypt again fell under the dominion of Heraclius, who restored the orthodox party, but before the close of his reign the country was conquered by the Arabs, and was never again a province of the Byzantine empire.

Heraclius.

Condition of Egypt under the Romans, and causes of its decline.

A review of the history of Egypt under the Romans presents a melancholy prospect of rapid decline, with scarcely a single time of prosperity to enlighten its dreariness. The main cause of this must have been the national character of the Romans, who, although they conquered bravely, held firmly, and governed wisely, cared alone for the outward welfare of the provinces. They sought not to inquire into the early history and former greatness of a state they ruled, except to draw out its physical resources and increase its commercial activity. Thus they did nothing to raise the character of the native Egyptians, whose affections were still occupied with the story of their former power and the remains of their ancient religion. While the Romans thus neglected the Egyptians, policy made them treat the Greeks but little better, except that they allowed them somewhat greater privileges, probably to make their influence balance that of the far more numerous Egyptians, and thus aid in maintaining a divided interest in the country. In addition to this, Egypt was weakened by the exactions of the governors and other officials. Internal causes, moreover, had no little share in producing the decline of the country. The people of Alexandria, uniting the discontent of the inhabitants of a degraded capital, with the ambition of men of letters, and the restlessness of an active commercial population, were constantly involved in dissensions among themselves and with their rulers, which became graver with the decline of the empire; while the native Egyptians, more and more oppressed and subject to the incursions of nomad tribes, relapsed into barbarism, but regained somewhat of their ancient courage. Hence arose revolts which were quelled with difficulty, and which had they been directed by military genius, and supported by an undivided people, would have restored the independence of Egypt. When Christianity acquired the ascendancy, religious contests took the place of political strife, until they became intimately connected with politics in the resistance of the Egyptians to the doctrines of the orthodox. Then national spirit was aroused, and the Greek and Roman parties, now formed into one, had to oppose the feeling of the whole country. The emperors generally acted with a short-sighted policy, and supported the foreign minority by employing force. It was found necessary to intrust the protection of the country to Greek or Roman soldiers alone, and thus when first the army of Khusroo and then that of 'Omar invaded Egypt, hatred for the Greeks, and the inability to defend themselves, rendered its subjugation comparatively easy.

Conquest by the Arabs.

In the year 639 of our era, the eighteenth of the Flight,[1] Egypt was invaded by the Muslims under the celebrated 'Amr Ibn-El-'A's (or, as some of the Arabian historians write it, El-'A'see). Entering the country from Syria, at the head of only 4000 men, he besieged Pelusium, and took it after thirty days. This town was still considered the key of Egypt on the Syrian frontier, and its capture was therefore an important advantage which opened the country southwards to the Arab general. He marched thence to 'Eyn-Shems, the ancient Heliopolis, where he found the Greeks collected in force, and commanded by John Mukowkis, or rather John the Mukowkis, or Gureyg the Mukowkis,[2] the governor

Battle at Heliopolis.

[1] The years of the Muslim era are generally used in this portion of the history, as they are more convenient to oriental scholars, and are often impossible to convert with exactitude into the corresponding years of our era, when the month in which an event took place is not specified. The principal dates are, however, given according to both methods of computation.

[2] According to the Kámoos, "the Mukowkis is a certain bird having a ring of black upon white, like the dove or pigeon; also, Gureyg (in some copies Gureyh) the son of Meenè (in the printed edition "Meenee"), el-Kibtee (i. e., the Copt), the governor of Misr and Alexandria, and the surname of every one who held dominion over these two cities." Thus a kind of ring-dove seems to have been the symbol of the governor of Egypt under the Greeks, like as the hawk was the symbol of the Pharaohs. Gureyg may be written Jureyj; and it is necessary to remark here that as the Arabic letter corresponding to the English g and j is pronounced hard in Egypt, it has been so written in this article, except when occurring in foreign names.

of Memphis, a native Egyptian. They offered a vigorous defence, but were put to the rout, and 'Amr advanced to the banks of the Nile and laid siege to Egyptian Babylon, a fortress of great strength, and garrisoned by a Roman legion. Here he received a reinforcement of 4000 Muslims, and after a protracted siege of seven months, he took the place by assault.[1] In an enemy's country, and far from all supplies, the small army of the Arabs was still in a critical position, and unable to push on against the capital, Alexandria, when the enmity of rival Christians and the perfidy of Mukowkis decided the balance in their favour. The persecutions which the Copts had suffered had greatly embittered them against the Greeks; and, as Gibbon observes, had "converted a sect into a nation, and alienated Egypt from their religion and government." Mukowkis, who governed Memphis, was in heart a Monophysite, and had also withheld the tribute due at Constantinople; and both he and his Coptic brethren, after the first resistance, hailed the new invaders as their deliverers from the Greek yoke. On the fall of Babylon they entered into a treaty with the Arabs, engaging to pay to them a poll-tax of two deenârs on every adult male, and agreeing to furnish them with supplies and assistance while completing the subjugation of the country. Having concluded this treaty, and founded the city of El-Fustât, on the site of his first encampment on the banks of the Nile, with the mosque known by his name, 'Amr marched against Alexandria; and after overcoming many obstacles, and disputing the whole way with the Greeks, who conducted their retreat, in the face of a victorious army, with great ability, in twenty-two days he appeared before it. Fresh warriors continued to arrive from Syria to strengthen the besieging force; but the defence was as obstinate as the attacks of the Muslims were brilliant, and was protracted for fourteen months. At length, on the 22d December 640,[2] the metropolis of Egypt, the first city of the East, capitulated; but it is said that this conquest was only achieved with the sacrifice of 23,000 Muslims. Abu-l-Farag relates that 'Amr, wishing, at the earnest request of John the Grammarian, to spare the famous Library, wrote to the Khaleefeh 'Omar, asking his instructions respecting it; and that he answered: "As to the books you have mentioned, if they contain what is agreeable with the book of God, in the book of God is sufficient without them; and if they contain what is contrary to the book of God, there is no need of them; so give orders for their destruction." The historian adds, that they were burnt in the public baths of the city, and in the space of six months were consumed.[3] The conquest of the rest of Egypt was soon effected, and the various strongholds successively fell into the hands of the conquerors. Bahnesè (Oxyrhynchus), a town of Middle Egypt, is stated to have withstood 16,000 Arabs for several months, and to have cost them 5000 of their number.[4]

Siege of Alexandria.

Arab lieutenants.

'Amr governed the country with much wisdom for four years, but was dismissed by 'Othmân, who appointed in his place Abd-Allah Ibn-Abee-Sarh. The latter reduced Alexandria, which had been retaken by the Emperor Constans II., and pushed his conquests beyond Africa Propria. He died at Ascalon, in the year 35, having governed eleven years.[5] His successor's rule was short, and the next viceroy, Mohammad, son of the Khaleefeh Aboo-Bekr, on assuming the reins of government, acted with such tyranny towards the followers of 'Othmân, that Mu'âwiyeh was compelled to despatch 'Amr to Egypt with a force from Syria, and a great battle was fought between the two armies of Muslims, in which Amr was again victorious. As a reward for this service, he was a second time appointed governor of Egypt, and he died there in the year 42.

From this time to A.D. 868, or for rather more than two centuries, Egypt was governed by a succession of viceroys, appointed by the Khaleefehs of Damascus and Baghdâd, Their period was distinguished by intestine troubles, and a constant change of rulers, resulting from the caprice of the Khaleefehs, or the vicissitudes of their fortunes. Here we may mention, that shortly after the overthrow of the Umawee Dynasty of Damascus, and the accession of the House of Abbâs, which ruled at Baghdâd, the city of El-Askar, immediately to the north-east of El-Fustât, was founded, and the seat of government removed thither. The site is without the walls of modern Cairo, and is marked by extensive mounds of rubbish.

Dynasty of the Benee-Tooloon. Ahmad Ibn-Tooloon.

In A.D. 868 (A.H. 254) Ahmad, the son of Tooloon, a Turkish slave who held a high office at Baghdâd, was appointed governor of the province of Misr by the Khaleefeh El-Moatezz, and not long after of that of Alexandria also, by his successor El-Muhtedee. After a rule of about a year as viceroy, in self-defence he threw off his temporal allegiance to the Khaleefeh and proclaimed himself sovereign of Egypt; but at the same time he endeavoured to avoid a complete rupture by continuing the prayer for the Prince of the Faithful in the mosques, and the mention of his name on the coins which he struck.[7] Later in his reign, however, he forbade the mention of the Khaleefeh's brother and colleague, El-Muwaffik, in the prayers and state-documents of Egypt, and El-Muhtedee, who was a weak prince, was prevailed on to denounce him publicly as a traitor from the pulpits throughout his dominions. Yet that he secretly favoured him is proved by his vain attempt to escape to Egypt from the tyranny of his warlike brother. Ahmad founded the Dynasty of the Benee-Tooloon, which lasted for a period of 37 years, and consisted of princes of his own family. He built the royal city of El-Katâë', between El-Askar and Mount Mukattam, enriched it with splendid buildings and constituted it the seat of his government. Its site is now covered with ruins, only his great mosque remaining, a proud example of his wealth and magnificence, still the largest mosque of Cairo, and curious as presenting the earliest specimens of the pointed arch. The reign of this vigorous and wise prince was remarkable for prosperity at home and conquests abroad. He took El-Barkah, and in Syria, in 264, captured Hims, Hamâh, and Aleppo; after which he proceeded to Antioch, and the governor refusing to surrender, he took that city by storm. He then advanced towards Tarsus, but his supplies failing, he was compelled to retire. About five years later Bedr-ed-Deen Lulu, his deputy, and governor of Aleppo, Kinnasreen, and Hims in Syria, and of Diyâr Mudâr in Mesopotamia, re-

[2] El-Mekeen. Eutychius, *Annales*.

[3] This tradition is, we believe, only mentioned fully by Abu-l-Farag, but he was a Christian, and Muslim writers would consider it an occurrence of no importance. Abd-el-Lateef merely says, "here was the library which 'Amr Ibn-El-'A's burned by permission of 'Omar;" and El-Makreezee, speaking of Pompey's Pillar, says, "it is said that this pillar is one of those which stood in the portico of Aristotle, who there taught philosophy, and that his academy contained a library which 'Amr Ibn-El-'A's burned by direction of 'Omar." See the *Englishwoman in Egypt*, vol. i., p. 40, *et seqq*.

volted and entered into a league with El-Muwaffik. It was apparently in an expedition against this rebel that Ahmad died, at Antioch, in the year 270.

Khumâraweyh.

Khumâraweyh, on the death of his father, was appointed his successor by the army, he being then twenty years old, in the days of El-Moatemid bi-llâh, and he inherited a kingdom extending from the Euphrates to Nubia. He fought a battle with the forces of the Khaleefeh, commanded by a son of El-Muwaffik (afterwards the Khaleefeh El-Moatedid), between Damascus and Ramleh; in which his army gained the victory, although, if we may believe Abu-l-Fidâ, he himself fled the scene of action in a panic, and his troops continued the fight without him. Ibn-Khallikân says that, when El-Moatemid died and El-Moatedid succeeded him, Khumâraweyh hastened to him with presents and asked him to marry his daughter, Katr-en-Nedâ, whose name was also Asmá, to El-Muktefee bi-llâh, son and appointed successor of El-Moatedid; but that El-Moatedid said, "Nay, but I will marry her to myself;" and, the biographer adds, this, they say, he did to impoverish Khumâraweyh, in which he succeeded.[1] In 281 he made an incursion into the Greek territory, and died in the following year. It is said that he was fearful of assassination; to avoid which he had trained a lion to guard him when asleep.[2] His fears were justified; for he was put to death by his women, or, according to some, by his eunuchs, at Damascus.

Geysh.

His son, Geysh Abu-l-Asâkir, succeeded him. This prince was killed in about eight months; his youth, which rendered him unfit to govern, occasioned his fall; for he had discarded from his society those who were in favour with his father, and associated with none but worthless men. He was succeeded by his brother, Hâroon, the principal events of the period of whose rule were a great tempest and earthquake in Egypt in 286, and a treaty which he concluded with the Khaleefeh, by which the provinces of Awâsim and Kinnasreen were ceded to him.[3] He reigned upwards of eight years, but gave himself up to pleasure, and was put to death by his uncles Sheybân and 'Adee, sons of the founder of the dynasty, the former of whom usurped the government.[4] In the meantime, at the instigation of the generals of Hâroon, Mohammad Ibn-Suleymân, a scribe of Lulu, advanced against him with a numerous and heavily-equipped army. Sheybân went forth to meet him with all the forces he could muster, but numbers of his troops deserted to the invader, and he was soon overthrown.[5] Mohammad Ibn-Suleymân burned El-Katâe' and sacked El-Fustât, reducing the women to slavery, committing many atrocities, and exiling the family of Ahmad Ibn-Tooloon, with all their adherents[6] (A.H. 292.)

Hároon.

Egypt subjugated by the Abbásees.

Arab lieutenants.

Having thus completed his conquest, and restored the province of Egypt to the House of Abbâs, Ibn-Suleymân yielded the government to 'Eesâ Ibn-En-Nósharee, appointed by El-Muktefee. He died in 297, and was followed by Tekeen El-Gezeree, under whose rule Egypt was invaded by the forces of Abd-Allah El-Mahdee, first prince of the Dynasty of the Fâtimees (or Fawâtim, that being thé plural of Fâtimee), which had succeeded the Benee-Aghlab in the dominion of Northern Africa. His general, Hubâsheh, having taken El-Barkah, advanced with an army of 100,000 men to Alexandria, where Tekeen, reinforced with troops from El-Irâk, give him battle, and defeated him in a sanguinary conflict.[7] In the following year he was succeeded by Abu-l-Hasan Zekee El-Aawar Er-Roomee, in whose time El-Mahdee again attempted the conquest of Egypt with an army under the command of his son, Abu-l-Kâsim Mohammad; Alexandria fell into his hands in 307; its inhabitants fled to Misr, and the governor entrenched himself in El-Geezeh, on the opposite or western bank of the Nile, and shortly afterwards died. In this emergency Tekeen was reinstated in his office. He immediately strengthened El-Geezeh with a second moat, and intercepted the forces of El-Mahdee by the river; and being reinforced by 3000 men from Baghdâd, under Moonas the Eunuch, he gave battle to Abu-l-Kâsim in the Feiyoom and at Alexandria, and drove him back to El-Barkah.[8] After rendering this important service, Tekeen was again recalled, and Hilâl Ibn-Bedr appointed governor; but the troops revolting, and much sedition and rapine ensuing, he was once more despatched to Egypt, where he remained until his death in the year 321.[9]

Unsuccessful invasion by El-Mahdee.

He was followed by Mohammad El-Ikhsheed Ibn-Taghag Aboo-Bekr El-Farghânee, afterwards the founder of the Dynasty of the Ikhsheedees, who was almost immediately superseded by another governor; and for one year more Egypt continued to be a province of the Khaleefehs of Baghdâd. In the year 323 El-Ikhsheed again succeeded to the government. About this time little remained to the Khaleefeh of his once broad empire beyond the province of Baghdâd, and even there his power was but nominal, for Er-Râïk there, as well as in Wâsit and El-Basrah, held the entire authority. Khoozistân, Persia, Kermân, Rei, Ispahân, El-Mosil, and the provinces of Mesopotamia, were either in a state of revolt, or nearly or wholly lost to him. Spain was governed by the Dynasty of Umeiyeh, and Africa by that of El-Mahdee; and we have seen the distracted state of Egypt since the fall of the Benee-Tooloon. El-Ikhsheed availed himself of these circumstances to throw off his allegiance, and possess himself of Egypt and Syria; continuing, however, to acknowledge the spiritual supremacy of the Khaleefeh. Shortly after he defeated the forces of El-Mahdee, who had again made an inroad into the country: and in 327 he was confirmed in his government by Er-Râdee.[10] In the following year Er-Râïk subdued a great part of Syria, and, having taken Damascus, advanced to the frontier of Egypt, where, after a very severe engagement, he was utterly routed, and pursued by the troops of El-Ikhsheed as far as Damascus. There, however, the fortune of war turned against El-Ikhsheed, and for a time he was deprived of the province of Syria, though he subsequently regained possession of it. During his reign, the Khaleefehs of Baghdâd were daily losing power, and, in the year 333, El-Muktefee wrote to him lamenting his miserable state; whereupon El-Ikhsheed immediately repaired to him at Rakkah with valuable presents, and offered him assistance, and an asylum in Egypt. About this time, also, he conducted a war with various success against Seyf-ed-Dowleh of Hamadân, who had attacked Syria. He died at Damascus in 334, in the 66th year of his age,[11] and was buried, as were

[6] El-Is-hâkee. El-Makreezee's *Khitat*.

[7] El-Is-hâkee. Of this expedition, Abu-l-Fidâ relates (in the events of the year 301) that it was commanded by Abu-l-Kâsim, who took Alexandria and the Feiyoom, but was repulsed by Moonas the Eunuch, whom El-Muktadir had despatched against him; and, in the events of the year 302, he says that El-Mahdee sent another expedition to Egypt by sea, that Alexandria was taken, and that he was again defeated by Moonas, and driven back with great loss.

[8] Abu-l-Fidâ says that this expedition was commanded by El-Kâïm, who, having proceeded to El-Geezeh, passed on to El-Ashmooneyn and subdued a great part of Upper Egypt, and being well supplied by sea, kept up the war with vigour; but that reinforcements having reached Egypt of twenty-five sail from Tarsus, Moonas gave him battle by sea and land on the same day, and completely routed his forces.

all the princes of his dynasty after him, in the mosque of 'Omar at Jerusalem.[1]

Abu-l-Kásim and Abu-l-Hasan 'Alee.

Of El-Ikhsheed's two sons and successors, Abu-l-Kásim and Abu-l-Hasan 'Alee, little is known; their wezeer Káfoor, a black eunuch, being the actual ruler. In the reign of the former, in the year 343, a great fire occurred in El-Fustát, which destroyed 1700 houses and much merchandise. Káfoor succeeded to the throne in 355, and was acknowledged throughout Egypt, Syria, and the Higáz. He ruled with great ability, and was a patron of literature: his name is celebrated by the poet El-Mutanebbee, who was his boon companion, and whom, as well as other learned men, he rewarded with magnificent presents. On his death internal dissensions respecting the succession of Abu-l-Fowáris, a son of 'Alee, presented a favourable opportunity to the Fátimee Khaleefeh to renew the often-repeated invasions of Egypt.

Káfoor.

Hitherto, with few exceptions, the most notable of which are the reigns of Ibn-Tooloon, Khumáraweyh, El-Ikhsheed, and Káfoor, the Muslim rulers of Egypt had not much benefited the country, or rescued it from the anarchy and troubles in which it had become involved under the Lower Empire. But the incidents of the time are so little known as to have been deemed worthy of more mention in this article than perhaps their importance would otherwise warrant. From the period at which we have now arrived, however, the annals of Egypt contain much important matter, and are so closely interwoven with the events of the Crusades as to render them deeply interesting to the student of European history. The rise of the schismatic Khaleefehs of Africa is a remarkable episode in the early days of El-Islám, and most of the princes of that dynasty were not unworthy of their successors, the renowned Saláh-ed-Deen and his family, or of the Memlook Sultáns.

Conquest by El-Mo'izz.

In the year 358 El-Mo'izz li-deeni-lláh, the fourth Fátimee Khaleefeh, equipped a large and well-armed force, with a formidable body of cavalry, the whole under the command of Abu-l-Hoseyn Góhar el-Káïd, a native of Greece, and a slave of his father El-Mansoor. This general, on his arrival near Alexandria, received a deputation from the inhabitants of El-Fustát, charged to negotiate a treaty. Their overtures were favourably entertained. and the conquest of the country seemed probable without bloodshed. But, while the conditions were being ratified, the Ikhsheedees prevailed on the people to revoke their offer, and the ambassadors on their return were themselves compelled to seek safety in flight. Góhar lost no time in pushing forward. Before El-Geezeh a partial combat took place: several days were passed in skirmishes, and at length he forced the passage of the Nile a few miles south of that town, at the head of his troops. Here the Ikhsheedees offered a brave resistance; the greater part were left dead on the field, and the remainder, taking what valuables they could carry off, fled from El-Fustát. The former mediators were now brought to intercede for the inhabitants and the women of the fallen dynasty, and, to the honour of the African general, it is related that they were pardoned, and the city was peaceably occupied. The submission of the rest of Egypt was secured by this victory; and all the Higáz, including the holy cities, and El-Yemen, speedily acknowledged the authority and supremacy of the Fátimee El-Mo'izz. In the year 359 Syria was also added to his dominions, but shortly after was overrun by the Karmatees; the troops of El-Mo'izz met with several reverses, Damascus was taken, and those lawless freebooters, joined by the Ikhsheedees, advanced to 'Eyn-Shems. In the meanwhile Góhar had fortified El-Káhireh[2] (the new capital which he had founded immediately north of El-Fustát), and taken every precaution to repel the invaders: a bloody battle was fought on Friday, the 1st of Rabeea el-Owwal, in the year 361, before the city walls, without any decisive result. On the following Sunday, however, Góhar obtained a great victory over the enemy, who experienced a reverse more complete than any he had before suffered, and the camp and baggage fell into the hands of the conqueror.

Foundation of El-Káhireh. Battle with the Karmatees.

At the earnest solicitations of his lieutenant, who had ruled Egypt both ably and justly, with almost absolute authority, El-Mo'izz at length determined to remove his court to his new kingdom. In Ramadán 362, he entered El-Káhireh, bringing with him the bodies of his three predecessors, and vast treasure. El-Mo'izz reigned about two years in Egypt, dying in the year 365. He is described as a warlike and ambitious prince, but, notwithstanding, he was especially distinguished for justice, and was fond of learning. He showed great favour to the Christians, especially to Severus, Bishop of El-Ashmooneyn, and the Patriarch Ephrem; and under his orders, and with his assistance, the church of the Mu'allakah, in Old Misr, was rebuilt. He executed many useful works (among others rendering navigable the Tanitic branch of the Nile, which is still called the canal of El-Mo'izz), and occupied himself in embellishing El-Káhireh. Góhar, when he founded that city, built the great mosque named El-Azhar,[3] the university of Egypt, which to this day is crowded by students from all parts of the Muslim world. The principal event of his reign in Egypt was the second irruption of Hasan the Karmatee. The enemy, as on the former occasion, reached 'Eyn-Shems; but now he gained more advantage over the African troops. Although twice defeated in different parts of Egypt, and constantly harassed in his advance, the capital was closely besieged by him, and its defenders were driven across the fosse. Thus straitened, El Mo'izz had recourse to stratagem, and succeeded in bribing Hasan Ibn-El-Garráh (who, with a body of the tribe of Tei, fought with the Karmatees) to desert them in the heat of the next battle. The result of this plan was successful, and again Hasan was defeated and compelled to flee. This event, which occurred in the year 363, relieved Egypt of another invader, an ally of Hasan, by name Abd-Allah Ibn-'Obeyd-Allah (formerly governor of Syria under Káfoor), and obtained for the arms of El-Mo'izz various successes in Syria.[4]

Foundation of the Azhar. Second invasion of the Karmatees.

El-'Azeez.

El-'Azeez Aboo-Mansoor Nizár, on his coming to the throne of his father, immediately despatched an expedition against the Turkish chief El-Eftekeen, who had taken Damascus a short time previously. Góhar again commanded the army, and pressed the siege of that city so vigorously that the enemy called to their aid the Karmatees. Before this united army he retired by little and little to Ascalon, where he prepared to stand a siege; but, being reduced to great straits, he purchased his liberty with a large sum of money. On his return from this disastrous campaign, El-'Azeez took the command in person, and, meeting the enemy at Ramleh, was victorious after a bloody battle, while El-Eftekeen, being betrayed into his hands, was with Arab magnanimity received with honour and confidence, and ended his days in Egypt in affluence.[5] El-'Azeez followed

War in Syria.

[1] El-Is-hákee.

[2] Modern Cairo. It was originally called El-Mansooreeyeh; El-Mo'izz, however, changed its name to that of El-Káhireh, by reason of an omen at its foundation. The *Khitat* contains a long account of the foundation of El-Káhireh, and of the three successive walls with which it was at different times encompassed. For details respecting this and the other capitals of Egypt under the Muslims, see the sketch in the *Englishwoman in Egypt*, vol. i., p. 124, *et seqq.*, in which the author has availed herself of the valuable MS. notes of Mr Lane.

[3] El-Is-hákee.

[4] For a detailed account of the reign of El-Mo'izz, see *Vie du Khalife Fatimite Moezz-li-din-Allah*, par Quatremère, Paris, imp. roy., 1837.

[5] Abu-l-Fidá. In 372 El-'Azeez again sent an army to Syria, and quelled a serious rebellion excited by El-Mufrig-Id.

his father's example of liberality. It is even said[1] that he appointed a Jew his wezeer in Syria, and a Christian to the same post in Egypt. These acts, however, nearly cost him his life, and popular tumult obliged him to disgrace both these officers. After a reign of twenty-one years, of great internal prosperity, he died (A.H. 386) in a bath at Bilbeys, while preparing an expedition against the Greeks, who were ravaging his possessions in Syria.[2]

El-Hákim. His cruelty and extravagances.

Though El-'Azeez was distinguished for moderation and mildness, his son and successor rendered himself notorious by very opposite qualities. El-Hákim bi-amri-lláh Aboo-'Alee Mansoor began his reign, according to Muslim historians, with much wisdom,[3] but afterwards acquired a character for impiety, cruelty, and unreasoning extravagance, by which he has been rendered odious to posterity. He is described as possessing at once "courage and boldness, and cowardice and timorousness, a love for learning and vindictiveness towards the learned, an inclination to righteousness, and a disposition to slay the righteous;"[4] and this character is fully borne out by his many extravagances. Of his cruelty numerous anecdotes are told us, especially in the discharge of his functions as Mohtesib, or "regulator of the markets and of the weights and measures," an office which he assumed, and in which he became the terror of the inhabitants.

His impiety.

But his cruelty was surpassed by his impiety. He arrogated to himself divinity, commanded his subjects to rise at the mention of his name in the congregational prayers (an edict which was obeyed even in the holy cities Mekkeh and El-Medeeneh[5]), and altered his name, which signifies "governing by the command of God," to El-Hákim bi-amru, or "governing by his own command."

The Druses.

He is most famous in connection with the Druses, a sect which he founded, and which still holds him in veneration, and believes in his future return to the earth. He had thus made himself obnoxious to all classes of his subjects, when,

Invasion.

in the year 397, he nearly lost his throne by foreign invasion. Hishám, surnamed Aboo-Rakwak, a descendant of the house of Umeiyeh in Spain, took the province of El-Barkah, with a considerable force, and subdued Upper Egypt. The Khaleefeh, aware of his danger, immediately collected his troops from every quarter of the kingdom, and marched against the invader, whom, after severe fighting, he defeated and put to flight. Hishám himself was taken prisoner, paraded in El-Káhireh, with every aggravation of cruelty, and put to death. El-Hákim having by vigorous measures thus averted this danger, Egypt continued to groan under his tyranny until the year 411, when he fell by domestic treachery. His sister, Seyyidet-el-Mulook, had, in common with the rest of his subjects, incurred his displeasure; and, being fearful for her life, she secretly and by night concerted measures with the Emeer Seyf-ed-Dowleh,

His assassination.

chief of the guard, who very readily agreed to her plans. Ten slaves, bribed by 500 deenárs each, having received their instructions, went forth on the appointed day to the desert tract south-east of El-Káhireh, where El-Hákim, unattended, was in the habit of riding, and waylaid him near the village of Hulwán, where they put him to death.

Edh-Dháhir.

He was succeeded by his son, Edh-Dháhir (commonly pronounced Ez-Záhir) bi-lláh Abu-l-Hasan 'Alee, who ruled with justice and moderation for nearly sixteen years.

Disturbances in Syria.

In 414 Aleppo was taken by Sálih son of Mardás; and although he was defeated and slain by an Egyptian force sent against him, a son, Shibl-ed-Dowleh Aboo-Kámil Nasr, yet retained possession of that city. At this time also Hasan, of the tribe of Tei before mentioned, had made himself master of Ramleh;[6] and indeed from this Khaleefeh's reign we may date the decline of the Fátimee power, especially in Syria.

El-Mustansir.

In the year 427, El-Mustansir bi-lláh Aboo-Temeem Ma'add came to the throne at the age of seven years. His reign occupied a long period, rendered memorable by the unparalleled troubles which befel Egypt. It commenced prosperously with the defeat and death of Shibl-ed-Dowleh. Aleppo was taken, the submission of the rest of Syria followed; and the general who had conducted the expedition against that province assumed its government. On his death, Mo'izz-ed-Dowleh, a brother of Shibl-ed-Dowleh, retook Aleppo;[7] but the various fortunes of this prince and his nephew Mahmood, from this time, and during the calamities of Egypt, are too complicated and subordinate to claim a place here. In the western provinces, the rebel El-Mo'izz (the third successor of Yoosuf Ibn-Zeyree, who was appointed governor on the conquest of Egypt), was punished by an irruption of wild Arab tribes in the pay of El-Mustansir.

War between the Fátimees and Abbásees.

In the year 450, the Fátimee Khaleefeh was publicly prayed for in Baghdád; a remarkable event, of which the immediate cause was briefly as follows: Abu-l-Hárith Arslán El-Besaseeree, a powerful Turkish chief exercising unbounded authority in that city, had fallen into disgrace, and received supplies of men and money from the Khaleefeh of Egypt; and while Togrul-Beg espoused the cause of the Abbásee Khaleefeh, his brother Ibraheem Eynál revolted, joined El-Besaseeree, and defeated Togrul-Beg. El-Besaseeree entered Baghdád, in which the combat continued to rage; and the unfortunate city was devastated by massacre and pillage. El-Mustansir was solemnly declared Prince of the Faithful, and the insignia of the legitimate Khaleefeh were sent to Cairo. The success of El-Besaseeree, however, was but transient: Togrul-Beg had, in the meantime, defeated and killed his brother Ibraheem; he then entered Baghdád in Dhu-l-Kaadah 451; and having despatched a force against El-Besaseeree, the latter fell in a battle near El-Koofeh.

Persecution of the Christians. Intestine troubles.

A persecution of the Christians of Alexandria occurred about this time; and in 454 commenced a desolating struggle between the Blacks and the Turks, both of whom had become numerous in Egypt. The former were succoured by the mother of El-Mustansir, herself a negress, while the command of the latter was taken by Násir-ed-Dowleh Ibn-Hamdán, a general of El-Mustansir, more than once governor of Damascus, and at this period governor of Lower Egypt. To this man's unscrupulous ambition was due much of the trouble which ensued. After many battles the Turks succeeded in destroying the power of their adversaries, and their leader assumed almost absolute authority, while they not only extorted from the Khaleefeh immense sums of money and treasure, but even rifled the tombs of his predecessors for the valuables which they contained. At the same time the bulk of the valuable library of the Fátimees was dispersed by these brigands. But the very power of Násir-ed-Dowleh threatened his overthrow. His sense of security in his position rendered him regardless of the support of the Turks; and when at length his schemes for the deposition of El-Mustansir brought matters to a crisis, a large portion of the army declared against him. Defeated and driven from the metropolis, he succeeded in possessing himself of Lower Egypt, and a terrible civil war raged between the contending parties.

Famine of El-Mustansir.

But an even heavier calamity afflicted Egypt. For seven successive years the inundation of the Nile failed, and with it almost the entire subsistence of the country, while the rebels intercepted supplies of grain from the north. El-Makreezee informs us that El-Askar and El-Katáë were depopulated, and that half the inhabitants of El-Fustát perished, while in El-Káhireh itself

Egypt. the people were reduced to the direst straits. Bread was sold for 14 dirhems the lb. loaf; and all provision being exhausted, the worst horrors of famine followed. The wretched people resorted to cannibalism, and organised bands kidnapped the unwary passenger in the desolate streets, principally by means of ropes furnished with hooks, and let down from the latticed windows. In the year 462, the famine reached its height. It was followed by a pestilence; and in the midst of these horrors, Násir-ed-Dowleh advanced on Cairo at the head of an enormous army: he was induced to withdraw by the promise of large concessions, only to repeat the attack, and finally to make himself master of the city, after having inflicted a signal defeat on the Khaleefeh, who became only the nominal ruler of Egypt; a condition which lasted until the assassination of this powerful rebel in the year 465.

State of Syria. While these events were occurring in Egypt, Syria was in a continual state of anarchy and war. A distinguished general, the Emeer el-Guyoosh Bedr-ed-Deen El-Gemálee, held the government of Damascus during these times; and now El-Mustansir wrote, recalling him to assume the office of Wezeer of Egypt. On the condition of being allowed to bring with him a veteran force, he, happily for the country, obeyed the summons, and to his talents was owing the restoration of order, and even prosperity which followed. By a massacre of Emeers at a grand banquet shortly after his arrival, and by numerous executions, he subdued all opposition in the capital; and in a series of brilliant victories annihilated the savage hordes who infested the country throughout its whole extent, having either been called to the aid of the contending parties, or voluntarily taken advantage of the universal anarchy to commit their lawless ravages.

Invasion of Egypt. In concluding this necessarily extended notice of the reign of El-Mustansir, the invasion of Atseez with an army of Turkumáns, Kurds, and Arabs, in the year 469, must be just mentioned. Spreading devastation around them, they encamped near Cairo; and in the first engagement defeated the forces of El-Gemálee; but fortune favouring him in a second battle, the enemy was totally routed with immense carnage.

El-Mustansir reigned 60 years, and died in the year 487. He was a weak prince, solely given up to pleasure.[1] El-Gemálee had governed with almost absolute authority and great ability, for a period of 20 years, dying only a few days before the Khaleefeh. While admiring El-Gemálee's talents, we cannot but condemn his severity. He built the mosque which gives its name to the mountain immediately S.E. of the citadel of Cairo (Gebel-El-Guyooshee), and the second wall of El-Káhireh, with its three principal gates, Báb-Zuweyleh, Báb-en-Nasr, and Bab-el-Futooh. These gates, which are very fine specimens of architecture, are said to be the work of three Greek brothers.[2]

El-Mustaalee. El-Mustaalee bi-lláh Abu-l-Kásim Ahmad succeeded his father; but a son of El-Gemálee, El-Afdal, had the principal management of the affairs of the kingdom. This Khaleefeh's reign is memorable for the First Crusade. El-Afdal had taken Jerusalem from the Turks in the year 1098; and a few months later it yielded to the Crusaders, after a siege of 40 days. El-Afdal arrived shortly after its fall with a reinforcement of 20,000 men, but he was defeated in the battle of Ascalon. Later, an Egyptian army, commanded by Saad-ed-Dowleh, was worsted by Baldwin, Count of Edessa, and the general was killed in the action. From this period, with the exception of some efforts made in the next reign, to the time of Saláh-ed-Deen (the Saladin of the Crusades), Egypt was too much occupied with intestine troubles to equip expeditions against the various parties who now struggled for the possession of Syria. El-Mustaalee died in the year 495. He is stated to have been a Sunnee—a strange anomaly in a dynasty of Shiya'ees.

Jerusalem taken by the Crusaders.

El-A'mir. His son El-A'mir bi-ahkámi-lláh Aboo-'Alee Mansoor, came to the throne at the age of five years, and until his arrival at manhood, the government was conducted by El-Afdal. The first act of the Khaleefeh, however, on taking it into his own hands, was to put his minister to death, and appoint in his stead a man whose wickedness obliged him to imprison him and afterwards condemn him to death. The rule of El-A'mir was chiefly remarkable for his impiety and tyranny, and for the successes of the Crusaders, who, having reduced many of the principal coast-towns in Syria, meditated the conquest of Egypt, and crossed the frontier, but were deterred from the prosecution of their enterprise by the illness of Baldwin, whose death took place at El-Areesh, on his way back to Jerusalem. El-A'mir was put to death in 524, at the town of El-Geezeh, it is said by partisans of El-Afdal, whose son then usurped the entire government, setting up, as Khaleefeh, El-Háfidh li-deeni-lláh Abd-El-Megeed, a grandson of El-Mustansir (El-A'mir having left no male issue), but without the usual ceremonies of installation. This wezeer, Aboo-'Alee Ahmad, even forbade the mention of El-Háfidh in the public prayer, and inserted his own name in his stead. He perished in a popular tumult, roused by his extortions and arbitrary rule, and El-Háfidh was duly declared Khaleefeh, and received the oaths of allegiance. After the death of Ahmad, he successively appointed three other Wezeers; but these proving equally refractory, he at length dispensed with that office altogether. He reigned nearly 20 years. The licentiousness of his son and successor, Edh-Dháfir bi-aadáï-lláh Aboo-Mansoor Isma'eel, occasioned his death in four years and seven months at the hand of his Wezeer El-Abbás.

El-Háfidh.

Edh-Dháfir.

El-Fáïz. El-Fáïz bi-lláh Abu-l-Kásim 'Eesa Ibn-'Alee was, on his accession, only five years of age, and the history of his times presents merely the contentions of rival Wezeers, of whom the chief were El-Melik Es-Sálih Taláë Ibn-Ruzzeyk, and his competitor El-Abbás, before named. The latter finding his power failing, gathered together the wealth he had amassed, and fled to Syria, where he fell into the hands of the Crusaders, who stripped him of all that he had, and detained him a prisoner. Eventually he was given up to Taláë, and crucified over the gates of the palace.

El-'A'did. El-Fáïz died in the year 555, and El-'A'did li-deeni-lláh Aboo-Mohammad Abd-Allah, a grandson of El-Háfidh, and the last of the Fátimee Khaleefehs, was raised to what was then but the shadow of a throne, the entire power being in the hands of Taláë, who by his oppression and cruelty well-nigh rendered El-'A'did, by nature benevolent and wise, as tyrannical as himself. He was assassinated by the secret orders of the Khaleefeh, and the latter to conceal his agency in this act, installed his son El-'A'dil in his place. At this time the well-known Sháwir was governor of the Sa'eed (or Upper Egypt), a post next in importance to that of prime minister. During the last three reigns the Wezeers had been rapidly increasing in power; and the annals of the period are entirely occupied with the rise and fall of potent grandees, all eager for a post which conferred on its possessor the supreme authority. At length, in the reign of this unfortunate prince, they consummated the ruin of the dynasty, and overwhelmed themselves in its fall. In 555, El-'A'dil dispossessed Sháwir of his government, and the latter had immediate recourse to arms, marched against his enemy, and succeeded in putting him to death. He then constituted himself Wezeer, but in his turn was compelled to flee from a more powerful rival, Ed-Dirghám. Noor-ed-Deen, the sultan of Damascus, received the fugitive with

The Wezeer Sháwir.

Egypt.

favour; and in the course of the next year (559) despatched an army to Egypt, under the command of Asad-ed-Deen Sheerkooh, to reinstate him.

Shâwir invokes the aid of Noor-ed-Deen.

In the meantime Ed-Dirghâm had been busy putting to death the great men of the empire; and having thus weakened his power, he offered but a feeble resistance, was overthrown in a battle near the tomb of the seyyideh Nefeeseh, on the S. of Cairo, and Shâwir was restored.

He quarrels with Noor-ed-Deen, and forms an alliance with Amaury.

No sooner, however, was this effected, than he forgot the engagements into which he had entered with Noor-ed-Deen, and threw off his allegiance to him. Sheerkooh retired to the Sharkeeyeh, and occupied the town of Bilbeys, and thence threatened Shâwir. In this position of affairs the latter had recourse to the Crusaders, who willingly responded to his call, and Amaury, king of Jerusalem, arrived with a considerable force. With these allies, Shâwir besieged his former protector in Bilbeys, until hearing of Noor-ed-Deen's successes over the Franks in Syria, they negotiated a peace, and permitted Sheerkooh to withdraw from Egypt.

Invasion by Noor-ed-Deen.

About two years later, Noor-ed-Deen, determined on punishing the treachery of Shâwir, again sent Sheerkooh into Egypt with a great army, and accompanied by his nephew, the famous Salâh-ed-Deen. Shâwir again sought to strengthen himself by an alliance with Amaury, from whom he received the first intelligence of the meditated invasion. Apprised of their knowledge of his movements, Sheerkooh changed his course from Bilbeys, entered the valley of the Nile at some distance above Cairo, and, crossing the river, marched northwards to El-Geezeh. Here he endeavoured to raise the people against Shâwir and his infidel confederates; and had in some measure succeeded when the superior forces of the enemy compelled him to retreat southwards as far as El-Bâbeyn, near Ashmooneyn, where he risked an engagement, and gained a complete victory. This success opened to the invaders the greater part of Egypt, and Alexandria itself fell into their hands. Salâh-ed-Deen was placed in that city with a numerous garrison, and his uncle departed to subdue the rest of Egypt. The Crusaders, however, at once closely invested Alexandria, and so pressed the siege for three months, as to oblige Sheerkooh to come to its relief. An honourable compromise was effected, by which the Syrians agreed to resign their conquests and evacuate Egypt.

Egypt invaded by Amaury.

But fresh troubles were in store for this unfortunate country. Amaury, irritated at the result of a campaign in which he had only lost, determined on an expedition against his recent ally; and, entering Egypt, took Bilbeys, putting its inhabitants to the sword, and laid siege to El-Kâhireh, his course being marked by the most dreadful barbarities. On his approach, the ancient city of El-Fustât was set on fire by order of the Wezeer, to prevent it falling into the enemy's hands, and it continued burning somewhat more than fifty days.[1]

Alliance between the Khaleefeh and Noor-ed-Deen.

El-'A'did now earnestly sought the aid of Noor-ed-Deen; and that monarch, actuated by religious zeal against the Franks, who had already felt his power in Syria, and by the desire of conquest, once more despatched Sheerkooh. In the meantime negotiations had been opened with Amaury to raise the siege of El-Kâhireh, on payment of an enormous sum of money; while, however, the conditions were yet unfulfilled, the approach of the Syrian army induced him to retreat in all haste. Sheerkooh and Salâh-ed-Deen entered the capital in great state, were received with honour by the Khaleefeh, and with obsequiousness by the perfidious Shâwir, who was contriving a plot which was fortunately discovered, and for which he paid with his head. Sheerkooh was then appointed Wezeer by El-'Adid, but dying very shortly, he was succeeded in that dignity by Salâh-ed-Deen.[2]

Egypt.

Salâh-ed-Deen (Saladin) appointed Wezeer.

Of the short period which elapsed before Salâh-ed-Deen's assumption of the title of Sultân, a few words will suffice. One of his first acts was to put to death the chief of the Eunuchs, and a revolt of the Blacks resulted; a combat took place in El-Kâhireh, in the street called Beyn-el-Kasreyn; and the malcontents being worsted, the disturbances were quelled. Bahâ-ed-Deen Karâkoosh, a white eunuch, who afterwards played a prominent part in the reign of Salâh-ed-Deen, was appointed to the vacant post. This gave the Wezeer great influence in the palace, of which he judiciously availed himself. In 566 we hear of Amaury with Greek allies unsuccessfully besieging Damietta; and in the following year, Salâh-ed-Deen conducted an expedition against the Franks to Ascalon and Ramleh; after which, a year later, he took Eyleh.

Campaign against the Crusaders.

In 567, by order of Noor-ed-Deen, he suppressed the name of El-A did in the congregational prayers, and substituted that of the Abbâsee Khaleefeh; a masterly stroke of policy to secure the adhesion of the orthodox Muslims. The last of the Fâtimees was lying dangerously ill, and his relations concealed from him his degradation. He died without the knowledge of it, and with him perished an illustrious but unfortunate dynasty.

Salâh-ed-Deen was thus relieved of the most serious obstacle on his way to the throne; yet he dared not throw off his allegiance to the Sultân of Damascus, but prudently waited for a favourable opportunity. Noor-ed-Deen's suspicions were already aroused, and he died while secretly preparing to proceed in person to Egypt.

Salâh-ed-Deen proclaimed Sultân. Eiyoobee Dynasty.

Salâh-ed-Deen almost immediately proclaimed himself Sultan of Egypt, and inaugurated his reign with a series of brilliant successes. With the conquest of El-Mo'izz, Egypt again took an important place among the nations; and by the wars of Salâh-ed-Deen it became the nucleus of a great empire. But military glory was not the sole aim of that prince and his successors; and the patronage they continued to extend to letters and the arts had the most beneficial effect upon the civilization of the country.

Salâh-ed-Deen, whose full appellation was El-Melik En-Nâsir, Salâh-ed-Deen Yoosuf Ibn Eiyoob acquired his greatest renown by his campaigns against the Crusaders in Syria. As these belong, however, more properly to the history of those wars than to that of Egypt, they will be more briefly noticed in this place than would otherwise be necessary.

Subjugation of great part of Syria.

The youth of El-Melik Es-Sâlih Ismâ'eel, the son and successor of Noor-ed-Deen, and the consequent confusion which prevailed in his dominions, gave Salâh-ed-Deen a fair pretext to occupy Damascus, as the guardian of the young prince, and enabled him to wrest from him his kingdom. He thus considerably enlarged his territory, made himself master of a great portion of Syria, and continued to consolidate his power in those parts until the year 573 (A.D. 1178), when Philip, Count of Flanders, laid siege to Antioch, and Salâh-ed-Deen entered Palestine. The latter having encamped before Ascalon, his troops ravaged the neighbouring country, and set fire to Joppa, until at length Baldwin (surnamed the Leper), king of Jerusalem, issued from Ascalon and gave him battle.

Victory of Baldwin.

The result was disastrous to Salâh-ed-Deen; his army was totally routed, and he himself fled alone on a dromedary. After this, however, he gained some partial advantages over the Christians; and a terrible famine induced him, two years later, to conclude a truce with the King of Jerusalem, and retire to Egypt.

In the year 576 he again entered Syria and made war on Kilij Arslân, the Seljuk Sultân of Anatolia, and on Leon, King of Armenia—the Cilicio-Armenian kingdom,—both

---

Salâh-ed-Deen enters Anatolia and Armenia, and prosecutes the war against the Crusaders.

of whom he forced to make terms of peace. Not long after his return, Salâh-ed-Deen departed from Egypt (A.H. 578) to prosecute a war with the Crusaders in which neither side desired peace. Their hostility was aggravated by the following circumstances: a vessel bearing 1500 pilgrims had been wrecked near Damietta, and its passengers captured; and to the remonstrances of the King of Jerusalem, the Sultân replied by complaining of the constant inroads made by Renaud de Châtillon. At this time, the latter turbulent chief undertook an expedition against Eyleh, and for this purpose constructed boats at Karak, and conveyed them on camels to the sea; but his flotilla was repulsed and the siege raised by a fleet sent thither by El-'A'dil, the brother of Salâh-ed-Deen, and then his viceroy; and a second attempt was still more unfortunate—the Christian captives on that occasion were sacrificed in the valley of Mina. Having threatened Karak, Salâh-ed-Deen encamped at Tiberias, and ravaged the territory of the Franks: he then besieged Beyroot, but in vain; and thence turned his arms against Mesopotamia, and subdued that country, but the city of El-Mósil successfully resisted him. In the meanwhile, the Crusaders contented themselves with miserable forays across the enemy's borders, and made no serious preparations for the return of their redoubtable antagonist. The latter having been almost everywhere successful in Mesopotamia, took Tell-Khâlid, and 'Eyn-Tâb, in Syria, and obtained possession of Aleppo; he again besieged Karak, ravaged the territory of Samaria, and later received the fealty of the lord of El-Mósil, but not the keys of the city.

He subdues Mesopotamia.

Renewed hostilities with the Crusaders.

In the year 1186 of our era, war again broke out between Salâh-ed-Deen and the Crusaders. The Sultân had respected a truce into which he had entered with Baldwin the Leper, and Renaud, before named, was the first to break it. The capture, by the latter, of a rich caravan, enraged Salâh-ed-Deen, who despatched orders to all his lieutenants and vassals, summoning them to assist in the "Holy War;" and he marched (A.D. 1187) from Damascus to Karak, and there laid close siege to Renaud; at the same time a large body of cavalry under the command of his son, El-Afdal, advanced on Nazareth; and here a body of 130 knights hospitallers and templars, seconded by a few hundred foot-soldiers, and encouraged by the heroic Jacques de Maillé, marshal of the Temple, by their devotion, immortalized their memory. Only the grand master of the Temple and two of his knights escaped from the unequal struggle. Soon after, Salâh-ed-Deen approached in person, at the head of an army of 80,000 men; and the Christians with their whole force encountered him on the shore of the lake of Tiberias. The result of the battle which ensued was the heaviest blow which had yet fallen on the Crusaders. Weakened by thirst, shaken by the flight of a part of their troops on the second day of combat, and overwhelmed by numbers, the knights fought with desperate courage, but at length were forced to the hills of Hitteem. A multitude fell in this bloody fight, and among the prisoners were Guy de Lusignan (the King of Jerusalem and successor of Baldwin), with his brother and Renaud de Châtillon. The number of prisoners is almost incredible; and the massacre of many of them is an indelible stain on the glory of the generally merciful Salâh-ed-Deen. Tiberias, Ptolemaïs (Acre), Nâbulus, Jericho, Ramleh, Cæsarea, Arsoor, Joppa, Beyroot, and many other places, successively fell into the hands of the conqueror. Tyre resisted his attacks; but Ascalon surrendered on favourable terms, and the fall of Jerusalem crowned these victories. The great clemency of Salâh-ed-Deen on this occasion is chronicled by Christian historians, though it is but slightly mentioned by the Muslims, who took offence at the favour shown to the enemies of their faith.

Battle of Tiberias or Hitteem.

Fall of Jerusalem.

After these events Tyre was again besieged; and when about to capitulate, was fortunately relieved by the arrival of Conrad, son of the Marquis of Montferrat, and the valiant defence of the town wearied Salâh-ed-Deen, who turned his arms against Tripoli; but here he met with no better success. Bohemond, Prince of Antioch, and at that time possessor of Tripoli also, was, however, glad to obtain a truce of eight months; and some strongholds (among others Karak) were taken. But now the fortune of war turned against the Sultân. The ever-memorable siege of Acre, maintained with equal constancy by both Christians and Muslims, lasted upwards of two years, and attracted the attention of the whole Western World. At length the immense reinforcements received by the besiegers, and the presence of Richard Cœur de Lion of England, and of Philip II. of France, enabled them to overcome all resistance, and the standards of the Cross floated on the ramparts of the city. A horrible act of barbarity was here perpetrated, 2700 Muslim captives were massacred in cold blood, in consequence of Salâh-ed-Deen's having failed to fulfil the terms of the capitulation; and the palliative plea of the heat of an assault cannot be urged in extenuation of this enormity. Richard has been accused of being its author; but Michaud believes with reason that it was decided on in a council of the chiefs of the Crusade. On another occasion, however, that king was certainly guilty of similar cruelty.

Siege of Acre.

Advance of Richard on Jerusalem.

After a period of repose and debauchery, the army of the Crusaders, commanded by Richard, directed its march towards Jerusalem. Salâh-ed-Deen harassed his advance on every point, rendered the cities and strongholds defenceless, and ravaged the country. Richard, nevertheless, was ever victorious; his presence struck terror into the Muslims, and he gained a signal victory over the Sultân in the battle of Arsoor. But dissensions among the chiefs of his army, and the uncertain temper of the commander himself, debarred the Crusaders from the attainment of their great object, the deliverance of the holy city; and when all the coast from Joppa to Tyre was in the hands of the Christians, and the army of Salâh-ed-Deen was threatened with disorganization, a treaty was concluded, and Richard set sail on his return to England. The glory acquired by Salâh-ed-Deen, and the famous campaigns of Cœur de Lion, have rendered the Third Crusade the most memorable in history, and shed a lustre on the arms of both Muslims and Christians greater than they ever attained in these wars, either before or afterwards.

Battle of Arsoor.

A peace concluded.

Death of Salâh-ed-Deen. His character.

Salâh-ed-Deen died about a year after the conclusion of this peace (A.H. 589, or 1193 of our era) at Damascus, at the age of fifty-seven years. Ambition and religious zeal appear to have been his ruling passions; he was courageous, magnanimous, and merciful; possessed of remarkable military talents, and great control over himself. His generosity, on almost every occasion, to the vanquished, combined with his faithful observance of his passed word, are lauded by the historians of the Crusades; the former brought on him much obloquy among his own fierce soldiers, and is a trait in his character which is worthy of note in the annals of a time when this virtue was extremely rare. While engaged in the conduct of his continual wars, he was not unmindful of the welfare of Egypt, and during his reign many public works were executed. Of these we may mention especially the citadel of Cairo, with the magnificent buildings which, until very recently, it contained; the third wall of the city; and the repair of the great canal called the Bahr Yoosuf, a very important and useful work. From the year 578, until the period of his death, he had not entered Egypt; but his brother El-'A'dil, and other princes of his family, successively governed that country, and the Eunuch Karâkoosh, who also defended Acre, held a large share of authority.[1]

[1] The principal narratives of the life of Salâh-ed-Deen are, Bohadini *Vita et Res Gestæ Sultani Saladini*; Arab. et Lat., ed. Schultens,

Egypt.

El-'Azeez.

On the death of Saláh-ed-Deen, his extensive dominions were divided chiefly among his sons, and Egypt fell to the lot of one of them, El-Melik El-Azeez Imád-ed-Deen Abu-l-Fet-h 'Othmân. The grandees supported his claim to the throne, and he proved himself worthy of their choice. In conjunction with El-'A'dil, we find him warring against the leaders of the Fourth Crusade. He reigned five years and ten days, and was succeeded by his son El-Mansoor Mohammad; his uncle El-Afdal being compelled to relinquish the government of Damascus and assume the regency of Egypt. Disagreement among the sons of Saláh-ed-Deen had occurred soon after that monarch's death, and now hastened the rise of El-'A'dil, who, by his military talents and other remarkable qualities, had excited the fears of even his brother. With the view of checking his growing ascendancy, El-Afdal formed an alliance against him with Edh-Dháhir, the Lord of Aleppo, and besieged him in Damascus; but coming to strife, they raised the siege early in 596. This attempt proved fatal to the power of El-Afdal. He was pursued to Egypt, in his turn besieged in El-Káhireh, forced to flee, and El-'A'dil was proclaimed Sultân.[1] Having dethroned El-Mansoor, he speedily recovered Damascus from the hands of the confederate brothers, and Syria with Egypt acknowledged his supremacy. El-'A'dil is especially known by his opposition to the Fourth and Sixth Crusades, the former of which took place before his accession to the throne. He repulsed the Christians near Nábulus, captured Joppa, and encountered the enemy between Tyre and Sidon. He was there defeated with heavy loss, and Sidon, Laodicea, Gibleh, and Beyroot were taken. But the Crusaders wasted their strength before the fortress of Thoron. El-'A'dil raised the siege of that place, and although afterwards he met with a reverse near Joppa, his adversaries bought a dear victory; and, having come to terms of peace, they returned to Europe. In the year 600 (A.D. 1204) he departed to Syria with the object of securing Jerusalem against threatened attacks, and concluded a truce which he offered to renew when about to expire; and to prove his good faith, strengthened that offer by promising to cede ten castles to the Christians. These overtures were refused, and the Muslim army drove the newly arrived king of Jerusalem, Jean de Brienne, back to Europe. Those who remained then professed their willingness to accede to conditions of peace, and we do not again hear of El-'A'dil in Palestine until 614 (A.D. 1218), when he was once more called thither to oppose the Crusades; but a serious invasion of Egypt by these troublesome adventurers hastily recalled its king, and he died of grief, it is said, on hearing of the advantages gained by them.[2]

El-Man-soor.

l-'A'dil.

Egypt invaded by Jean de Brienne.

El-Kámil.

El-Kámil immediately came to the throne, and took the most energetic measures for the protection of his kingdom. In the meantime, the Franks[3] besieged Damietta both by sea and land; and notwithstanding every effort for the relief of the place, its garrison was forced to capitulate. El-Kámil summoned to his aid the princes of his family, and with every available man watched the enemy's movements. Flushed with success, Jean de Brienne commenced his march on the capital; and with the characteristic carelessness of the Crusaders, he took no measures to secure supplies. His advance was stopped at the junction of the canal of Ashmoon with the Nile, where he found El-Kámil in a very strong position. Encamped on the opposite shore, the invaders depended for supplies on Damietta and its immediate district; but the inundation of the Nile gradually obstructed land-carriage, and El-Kámil skilfully availed himself of this natural ally, caused boats to be carried overland to the enemy's rear, and, thus cut off by land and water, they were compelled to attempt a retreat. At Beyramoon, however, all further progress was found to be impossible—the inundation had covered the level country, and the Sultân's boats blockaded the Nile. They surrendered, and evacuated Damietta, but not before Egypt had suffered severely from the ravages they committed. The city of El-Mansoorah was founded on the site of El-Kámil's camp, and commemorates his energy and sagacity. The Seventh Crusade was invited by the same Sultân who had thus suffered by an invasion of the Franks. In A.D. 1228, El-Kámil invoked the aid of Frederick II. against his brother El-Muadhdham, Lord of Damascus, and, in consequence of this alliance, Jerusalem, with Bethlehem and the places between it and Joppa and Acre, Nazareth and the territory of Thoron and Sidon, with its dependencies, was ceded to Frederick on the 20th of Feb. 1229. Between these two monarchs existed the most friendly relations, presenting a curious spectacle in the midst of the intrigues and hatred of their subjects for each other, and endangering their popularity and even their lives. After various expeditions against his brother and his successors, El-Kámil gained possession of Damascus, and died there in the year 635[4] (A.D. 1238). He was distinguished by military talents, and rare moderation, and was also a learned man, a patron of the arts, and a good king.

Egypt.

Alliance with Frederick II.

El-'A'dil II.

His son El-Melik El-'A'dil the Younger, was declared Sultân of Egypt and Syria, with the consent of the nobles, and he speedily banished those ministers whose counsels he feared, and appointed creatures of his own. Oppressed by his tyranny, and impoverished by his extravagance, the people called his brother Es-Sálih Negm-ed-Deen Eiyoob to the throne; and he deposed and imprisoned El-'Adil in the year 637, and, to replenish his exhausted treasury, ordered all who had received presents from the late Sultân to restore them to his successor. In the next year serious disturbances broke out in Syria; Sálih 'Imád-ed-Deen, who had taken Damascus in the reign of El-'A'dil, formed an alliance with the Franks, and purposed the conquest of Egypt: the hostile armies met at Acre, and the Muslim soldiers of 'Imád-ed-Deen deserting to the banner of Es-Sálih Eiyoob, the Franks were routed. Negotiations for peace were then attempted, but these failing, the Franks were again induced to take the field by the cession of Jerusalem and other places. The king of Egypt, on his part, called to his assistance the Kharesmees, who took Jerusalem and overran Syria. In the next campaign they were joined by the army of Es-Sálih, under the command of his favourite slave Beybars, who was destined to play a conspicuous part in Egyptian history. The allied army met the Franks, eager to avenge themselves on the Kharesmees for the horrible atrocities of which they had been guilty in the preceding campaign, and willingly joined by the Muslim princes of Damascus, Hims, and Karak; on the first day the battle raged with unabated fury from daybreak to sunset, and was continued on the morrow until the prince of Hims, having lost 2000 men, gave way and fled towards Damascus. The Christians maintained the unequal fight

Egypt.

with great constancy, and were only vanquished after the greater number had fallen. In these encounters 30,000 men (either Christians or Muslims) were either killed or taken prisoners. Various successes followed this victory, Jerusalem was taken by the Egyptians, and Es-Sálih laid siege to Damascus in person. The city having capitulated on favourable conditions, his fierce allies, enraged at the loss of pillage, quarrelled with him, and soon after joined his rebellious subjects. Damascus was reduced to the direst straits, but again fortune favoured Es-Sálih. He hastened from Egypt, whither he had returned, and totally defeated the enemy. Other advantages were gained by his commander Fakhr-ed-Deen over the Franks in the ensuing year.[1]

Crusade of St Louis.

Although attacked by illness, the Sultán was once more called to Syria to quell fresh troubles; but at Damascus news reached him of the threatened invasion of Egypt by the Crusaders under St Louis, and he travelled back in great suffering from his malady. Damietta, which he rightly judged would be the first point of attack, was strengthened and well stored, and its defence was intrusted to Fakhr-ed-Deen.

Capture of Damietta.

On Friday, June 4, A.D. 1249, the French anchored before the place, and the next day landed opposite the camp of the Egyptian general, who offered but slight opposition, and in the course of the next night betrayed his trust and retreated southwards. His army was precipitately followed by the entire population of Damietta, and thus this important town with its stores fell into the hands of the invaders without a blow. Fakhr-ed-Deen nearly lost his life for this act of cowardice, and 54 of his principal officers were put to death. In the meantime the Sultán's illness gradually increased, but nevertheless he caused himself to be removed to the town of El-Mansooráh, which he fortified, and there he expired on Nov. 21, at the age of forty-four, and after a reign of ten years.

Death of Es-Sálih.

He it was who introduced the Bahree Memlooks, a body of Turkish slaves, who composed his body-guard, and eventually usurped the supreme power. Their name *Bahree* (or "of the river") originated in their being trained and quartered on the island of Er-Ródah, where the Sultán had built a palace.

The French were advancing southwards, and, notwithstanding the precautions of Sheger-ed-Durr (the widow of Es-Sálih, who assumed the regency), were apprised of the death of the Sultán. Many partial actions took place on the march, and on Dec. 19, their army appeared before El-Mansooráh, the scene of the disaster of Jean de Brienne. Skirmishing continued until Shrove Tuesday, when, a traitor having shown the enemy a ford over the canal of Ashmoon, they surprised the camp and town.

Engagements at El-Mansooráh.

Very severe fighting ensued, Fakhr-ed-Deen fell early in the struggle, and the place was nearly lost, when the Bahree Memlooks led by Beybars furiously charged the assailants, and completely turned the fortune of the day. The morrow witnessed another battle, also disastrous to the Crusaders, and a succession of misfortunes followed.

Toorán Shah.

Toorán Sháh, on hearing of the death of his father, travelled in all haste from Mesopotamia to Egypt, and having reached the camp, assumed the command. He had recourse to the stratagem which had proved so successful under the direction of El-Kámil, and cut off the supplies of the enemy. This, coupled with disease, soon reduced St Louis to great straits, and he sent to propose a truce, but not coming to terms he determined on retreating to Damietta.

Surrender of the Crusaders.

A memorable conflict took place by land and water, and St Louis with his troops surrendered themselves prisoners of war.

Toorán Sháh now gave himself up to debauchery, offended his nobles by bestowing his favours only on certain creatures whom he had brought with him from Mesopotamia, and alarmed the queen by forcing her to render him an account of his father's wealth. Sheger-ed-Durr appealed to the Memlooks, a conspiracy was formed, and the Sultán was attacked in his palace.

Murder of Toorán Sháh.

He fled to a pleasure tower built on the banks of the Nile, which was set on fire in the presence of his army, the wretched king, from the summit, in vain promising to abdicate. He perished miserably, and his unburied corpse lay for many days on the bank. On his accession he had strangled a brother, and his fate deserves no pity.

Queen Sheger-ed-Durr, first sovereign of the Bahree Dynasty.

Sheger-ed-Durr (vulgarly called Shegeret-ed-Durr), herself a slave, and the first of the Dynasty of the Bahree, or Turkish Memlooks, succeeded to the throne; and 'Izz-ed-Deen Eybek was appointed commander of the forces. After many delays, St Louis agreed to pay 400,000 livres as a ransom for himself and his army, 200,000 to be paid in Egypt, and the remainder on the fulfilment of certain stipulations at Acre; Damietta was surrendered and Egypt evacuated. Thus ended the last invasion of Egypt by the Crusaders.[2] Sheger-ed-Durr, in order to strengthen herself on the throne, shortly after married the Emeer Eybek, and caused him to be proclaimed Sultán, with the title of El-Melik El-Mo'izz, in the year 648.[3]

El-Mo'izz-Eybek.

The followers of Es-Sálih, however, obliged him to associate with himself in the sovereignty a young prince of the family of Eiyoob, El-Melik El-Ashraf Mudhaffar-ed-Deen Moosa.

El-Ashraf Moosa.

En-Násir, Sálah-ed-Deen Yoosuf, a son of El-'Azeez, invaded Egypt, and after many combats was driven back to Syria; but the country continued in a very unsettled state. The chief of the adherents of the fallen dynasty was arrested by Eybek; and Beybars, with other leading men, having repaired to the citadel to demand satisfaction, his bloody head was thrown to them from the ramparts, and in terror they fled to Syria. El-Ashraf was then cast into prison, and there he died. But Eybek soon roused the jealousy of his beautiful and ambitious wife; and he was assassinated by her orders. In her turn she was beaten to death, not many days after, by the wooden clogs of the female slaves of another wife of Eybek, and her corpse was exposed for three days in the moat of the citadel.

El-Mansoor 'Alee.

El-Melik El-Mansoor Noor-ed-Deen 'Alee, son of Eybek, was now raised to the throne, and Beybars being apprised of the death of his rival attempted to regain his power in Egypt; but Kutz, the viceroy of Eybek and also of his son, attacked and routed him; and he soon after deposed El-Mansoor, and declared himself Sultán.

El-Mudhaffar Kutz.

El-Melik El-Mudhaffar Kutz began his reign by putting to death El-Mansoor, and Sharaf-ed-Deen, the able minister of the last Eiyoobee kings, and of the first of this dynasty. A reign thus cruelly commenced ended tragically. Kutz was diverted from these severe measures by the advance of Hulágú, grandson of Genghis-Khán, who, with a formidable army, overran El-'Irák and Syria. By great efforts Kutz raised a considerable force and marched to meet him. The intelligence of the death of the Mongol emperor had, however, in the meantime recalled Hulágú, who left Ketbughá to encounter the Egyptian Sultán. The battle declared in favour of the latter, and Syria was restored to his rule. Returning in triumph to Egypt, he was assassinated on the frontier by Beybars, in the year 658, and this Memlook (who had but recently fought under his banner against the Tatars) was forthwith chosen by the Emeers to be his successor.

The brilliant reign of El-Melik Edh-Dháhir Beybars

Egypt.

Edh-Dháhir Beybars.

Campaign in Syria.

El-Bundukdâree is so perplexed and full of incident as to render a concise account of it very difficult. It commenced with the reduction of a revolt in Syria. The rebels were supported by a Tatar army under Hulâgû, but Beybars was everywhere victorious, and Damascus surrendered at discretion. Having subdued all opposition in this quarter, he endeavoured to improve the condition of Egypt, abolished the exorbitant imposts under which the people groaned, and welcomed to his court Ahmad, son of the Khaleefeh Edh-Dháhir, who was declared Prince of the Faithful with the title of El-Mustansir bi-llâh, and furnished with a small force, by which he hoped to establish himself in Baghdâd. He was, however, repulsed by the Tatars and put to death. The succeeding line of Khaleefehs, possessed of spiritual, but no temporal authority, remained at the court of the Memlook Sultâns until the Turkish conquest. From this time, Beybars continued to extend and confirm his rule. His first expedition was to Syria against the Christians, and the Church of the Nativity at Nazareth was destroyed. Thence he went to the fortified town of Karak, which had more than once resisted the attacks of Salâh-ed-Deen, but opened its gates to the Memlook conqueror, and its territory was added to his dominions. A great scarcity afflicted Cairo in 662, and Beybars threw open the government stores, and strove in every way to alleviate the sufferings of his subjects.

The Abbásee Khaleefehs in Egypt.

Beybars attacks the Christians.

Campaigns against the Christians.

In 663, he again entered Syria, and took Cæsarea and Ursoof; and in the next year he commenced a series of campaigns against the Christians, notwithstanding the earnest remonstrances of the kings of France, of Arragon, and of Armenia. To raise the necessary funds for the expenses of the war, he took occasion of the occurrence of many incendiary fires in Cairo, during his absence on this war, to mulct their co-religionists of the sum of 500,000 deenârs,[1] ostensibly to repair the damage caused by these fires. He threatened Acre, and took Safad; and relieved from the apprehensions caused by the advance of the Tatars by the death of Hulâgû, and the retreat of his army, Beybars despatched a force which effected the conquest of Armenia, and penetrated to the borders of Anatolia; a transient success which was speedily annulled by the advent of Abaka Khân, the son of Hulâgû. In the next war, Beybars again attacked the Christians, burning their churches and enslaving the people. He took Antioch, with horrible carnage, advanced to Hims, and Hamâh, and thence returned to Cairo. After a campaign against the Tatars, he ravaged the country around Acre (which place appears to have been the constant object of his attacks) and the "Assassins," so long the terror of dynasties, submitted to his power. About this time the Tatars renewed their inroads and besieged Beyrah; and in the year 671 Beybars took the field against them with two armies, one commanded by himself in person, the other by Kalâ-oon El-Elfee. In the battle of Beyrah the Sultân was completely victorious, and the Tatars fled to the mountains of Kurdistân. In consequence of this victory, Armenia again fell into his hands, and was given up to pillage. Abaka Khân afterwards was again repulsed at Beyrah. Nubia also about this time acknowledged the authority of Beybars. He died at Damascus in the year 676, after another expedition against Anatolia, attended with various success, in which the Tatars were leagued against him.[2] Great military talents, coupled with the most indefatigable activity, Beybars certainly possessed, but he used his conquests unmercifully; on many occasions he ravaged whole provinces, and sacked many towns, putting great numbers of the inhabitants to the sword. The melancholy annals of the Crusades bear ample testimony to this fact; and while the example of other monarchs, and of the Franks themselves, may be urged as some palliation, nevertheless his barbarity remains an indelible blot on his character. In Egypt he endeavoured to reform abuses and suppress vice; and numerous public works were executed by his orders. Damietta was razed and rebuilt farther inland; and the mouth of the Nile was protected by a boom against sudden invasion. He repaired the fortifications of Alexandria, and the Pharos, the mosque El-Azhar in Cairo, and the walls of the citadel, and built the great mosque known by his name to the north of the city.[3]

Fall of Antioch.

War with the Tatars.

Expedition in Anatolia.

Character of Beybars.

Es-Sa'eed Barakeh Khân.

El-'A'dil Selâmish.

El-Mansoor Kalâ-oon.

The son and successor of Beybars, El-Melik Es-Sa'eed Barakeh Khân, was exiled after a short reign, and a younger brother, El-'A'dil Selâmish, raised to the throne; Kalâ-oon El-Elfee acting as regent. This Memlook had married a daughter of Beybars, and was consequently nearly allied to the Sultân. He, nevertheless, conspired against him, and was soon proclaimed king by the title of El-Melik El-Mansoor. Distinguished in former wars, he achieved many successes during his reign of ten years. On his accession he despatched an army to reduce disturbances in Syria, and took Damascus. Peace was thus established in that province; and in the year 680,[4] he, in person, defeated a very superior force of Tatars, and raised the siege of Rahabeh. Later in his reign (in the year 688) he besieged Tripoli, which for nearly two centuries had been in the possession of the Christians, and was very rich and flourishing. The town was sacked, and its unfortunate inhabitants put to the sword.[5] His memory is still preserved in Cairo by his hospital and mad-house, adjoining his fine mosque in the principal street of the city. This charitable institution he is said to have founded for expiation of great severity towards the citizens, in enforcing an obnoxious edict. His son, El-Ashraf Khaleel, rendered himself famous by the siege and capture (in the year 690) of Acre, the last stronghold of the Crusaders in Syria. Many thousands of its inhabitants were massacred; and 10,000 who presented themselves before the Sultân and demanded quarter were slaughtered in cold blood.[6] He also took Erzeroom in 691, and two years after was assassinated in Egypt.

El-Ashraf Khaleel.

En-Násir Mohammad.

El-'A'dil Ketbugha

El-Mansoor Lágeen.

El-Melik En-Násir Mohammad, another son of Kalâ-oon, succeeded him at the age of nine years. The regent Ketbughâ, however, followed the example of Kalâ-oon, and usurped the sovereignty, with the title of El-Melik El-'A'dil. Pestilence and famine were followed by war with the Tatars, who again ravaged Syria. Ketbughâ despatched an army against them, but the valour of his troops was unable to withstand overpowering numbers, and Lâgeen Kalâ-oon's, governor in Syria, was driven into Egypt with an immense crowd of fugitives. Ketbughâ was deposed on the allegation that he had not commanded in person,[7] and El-Melik El-Mansoor Lâgeen was elevated in his stead. In little more than two years this king fell in a conspiracy. His character was amiable, and he deserved a better return for the equity and kindness he showed to his subjects.

A short period of confusion then ensued, during which an Emeer was proclaimed king. En-Násir Mohammad,

[7] El-Makreezee merely says that Ketbughâ led an army to Syria; and that on his return his assassination was attempted by certain of his Emeers near Ramleh, but that he effected his escape. See Quatremère's translation, tom. ii., livr. ii., p. 35, *et seqq.*

Restoration of En-Násir.

Great victory over the Tatars.

however, was at length recalled from his exile at Karak, and elected Sultán in the year 698.[1] Having firmly established himself in Egypt, he led an army against the Tatars, but met with a severe reverse in the plains of Hims; a second expedition proved more fortunate, and this general, then only nineteen years of age, gained a bloody and decisive victory over the enemy near Damascus, in the year 702. The battle lasted three days; during the first two the result was not decisive, although En-Násir held the field; on the third day the Tatars were utterly routed and pursued for many hours.[2] The Sultán on his entry into Cairo after this achievement, was preceded by 1600 prisoners, each one carrying the head of a comrade slain in the combat, and 1000 other heads were borne on lances in the procession. En-Násir reigned until the year 708, when he went to Karak and voluntarily abdicated; he had long struggled against the control of two powerful Emeers, Beybars and Silár; and in despair of throwing off their ascendancy, he then openly yielded the reins of government to those who had long really held them. Since this prince's accession, the Christians and Jews of Egypt suffered the most severe persecution (excepting that of El-Hákim) which had yet befallen them. In the year 700, they were ordered to wear, respectively, blue and yellow turbans, and forbidden to ride on horses or mules, or to receive any government employment. The people took advantage of these measures to destroy many churches and synagogues. The churches continued shut for about a year; but some of those which had been destroyed were afterwards rebuilt at the request of Lascaris and other princes.[3] Another event of this period was a great earthquake which half ruined Cairo, giving it the appearance of a city demolished by a siege; Alexandria and other towns of Egypt, as well as Syria, also suffered from it considerably.[4]

En-Násir abdicates.

Persecution of the Christians and Jews.

El-Mudhaffar Beybars II.

On the abdication of En-Násir, El-Melik El-Mudhaffar-Rukn-ed-Deen Beybars was saluted Sultán; but ere long En-Násir recovered his courage, and having collected an army, marched to Damascus, where he was acknowledged, and thence to Egypt, entering Cairo without opposition. El-Mudhaffar had fled at his approach, and, never a favourite of the people, he was attacked, on his exit from the metropolis, by a crowd of the citizens, who loaded him with abuse, and pelted him with stones. En-Násir now for the third time ascended the throne of Egypt, and took the entire authority into his own hands. The remainder of his life was a period of profound peace, during which he occupied himself in improving his dominions, and in embellishing Cairo. But another persecution of the Christians occurred in 721, and all the principal churches in Egypt were destroyed by certain fanatical Muslims. The Sultán threatened a general massacre of the inhabitants of El-Káhireh and El-Fustát; the Christians, however, took revenge themselves by setting fire to very many mosques and houses in the metropolis; much tumult ensued, and many Christians and Muslims were executed. The threats of the mob compelled En-Násir to permit the people to murder and plunder any Christian whom they might meet in the streets; and the oppressive rules before enacted were rigorously enforced, and made even more degrading.[5]

En-Násir again restored.

Great persecution of the Christians.

El-Mansoor Aboo-Bekr. El-Ashraf Koojook.

The sons of En-Násir followed him in succession, but the reigns of most of them were short and troublous. El-Melik El-Mansoor Seyf-ed-Deen Aboo-Bekr, El-Ashraf 'Alá-ed-Deen Koojook, En-Násir Shiháb-ed-Deen Ahmad, Es-Sálih 'Imád-ed-Deen Ismá'eel, El-Kámil Zeyn-ed-Deen Sháabán, and El-Mudhaffar Zeyn-ed-Deen Hággee, were only raised to the throne to be either exiled or put to death. After these, the Sultán Hasan deserves notice. He was deposed by his brother, Es-Sálih Saláh-ed-Deen—whose minister was Sheykhoon, a man well known to students of Egyptian subjects; but he soon regained his authority, reigned seven years, and at length fell by the swords of his Memlooks in the splendid mosque which he built in the open space beneath the citadel of Cairo. Four more Memlook kings bring the history to the accession of a new dynasty, that of the Circassians. These were El-Mansoor Násir-ed-Deen Hággee (son of El-Mudhaffar), deposed in six months; El-Ashraf Sháabán (son of Hasan), an unfortunate prince, whose reign passed away amid the struggles of the now too powerful Emeers,[6] by whom he was ultimately strangled; his son, El-Mansoor 'Alá-ed-Deen, the victim of similar troubles, and in whose time the celebrated Barkook rose to the regency; and Es-Sálih Hággee, a brother of the last king. Exiled by Barkook, who was proclaimed Sultán, he unsuccessfully endeavoured to recover his throne in the year 784, and in 790 was restored, but he was soon once more dethroned, and this time with the loss of his life, by Barkook.

En-Násir Ahmad. Es-Sálih Ismá'eel. El-Kámil Sháabán. El-Mudhaffar Hággee. The Sultán Hasan. Es-Sálih Saláh-ed-Deen. El-Mansoor Hággee. El-Ashraf Sháaban. El-Mansoor 'Alá-ed-Deen. Es-Sálih Hággee.

Edh-Dháhir Barkook, founder of the Burgee Dynasty.

The Sultán Edh-Dháhir Seyf-ed-Deen Aboo Sa'eed Barkook was now undisputed master of Egypt. He was the first prince of the Dynasty of Burgee or Circassian Memlooks. As the preceding dynasty was founded by the Turkish Memlooks of Es-Sálih Eiyoob, so this dynasty was composed of the Circassian slaves whom those kings from time to time bought with the view of strengthening their power. They were originally placed in garrison-towns, and hence their name *Burgee*, signifying "of a tower or castle." It is worthy of remark, that, while many of the Sultáns of both these dynasties held an insecure tenure of power, many of the former met with a violent death, but few of the latter.[7] The reign of Barkook is memorable for his war with Teemoor, or Teemoor-lang, commonly called by us Tamerlane, who had extended his conquests towards his dominions, but found him not unprepared, for he had foreseen the threatened danger. In the year 795, Kará Yoosuf, lord of El-Medeeyeh, and Ahmad Ibn-Uweys, Sultán of Baghdád, fled to his court for succour. The inhabitants of Edessa had been put to the sword, and Aleppo was menaced with a similar catastrophe, when Barkook, at the head of his army, came to its relief. Ahmad was reinstated in Baghdád, as a vassal of Barkook, whose name appeared on the coinage; and soon after Báyezeed, commonly called by us Bajazet, conducted a treaty with the Sultán of Egypt. The conquest of India diverted Teemoor from his projects in Syria, but Barkook continued vigilant, and by every means sought to insure the safety of his kingdom. He died suddenly in 801, much beloved by his subjects, and regarded by less powerful chiefs as their strongest bulwark against the Tatar monarch. He was called "Sheykh" for his wisdom and learning, and combined with these qualities those of a skilful general and a good king. He was active, wary, and provident; and possessed the military talents of Beybars, without his severity. He seems to have been fond of riches and display, and he certainly left his treasury in a very flourishing condition, besides much wealth in stores, slaves, horses, and the like.[8]

War with Teemoor-lang.

En-Násir Farag.

His son, El-Melik En-Násir Abu-s-Sa'ádát Farag, fell a prey to intestine troubles and the inroads of the invader. He

[6] Not a little of this turbulence was excited by the constantly intriguing Khaleefehs, who used their religious influence against their patrons, at whose court they were indeed but guests. [7] See *Englishwoman in Egypt*, vol. i., pp. 225–9. [8] Abu-l-Mahásin.

Egypt.

Teemoor-lang defeats Farag.

had overcome a revolt of the governor of Syria, when Teemoor again threatened that province. Karà Yoosuf and Ahmad sought refuge with the son of their former protector, and Farag's refusing to betray his guests gave occasion to the enemy to continue the war; a battle was fought, Farag was defeated, Aleppo and Hims fell into the hands of the victor, and the Egyptian forces returned and were concentrated in Egypt. Intimidated, however, by the fall of his ally Bâyezeed, Farag sent an embassy to Teemoor with presents and offers of amity, and at length concluded a peace at the sacrifice of territory. Teemoor died in the year 807 (A.D. 1405), and Farag was preparing an expedition to recover his Syrian possessions, when he was surprised in his palace by an insurrection, headed by his brother, 'Abd-el-'Azeez, and compelled to take to flight. The people, believing that he had perished, proclaimed El-Mansoor 'Abd-el-'Azeez his successor. In the space of less than three months, however, he was deposed in favour of Farag, who thenceforth reigned at Damascus, until the Khaleefeh El-Musta'een bi-llâh, at the instigation of the Emeer Sheykh El-Mahmoodee, who had raised an army, boldly declared himself Sultân, by an appeal to religion gained numbers to his side, instituted criminal proceedings against Farag on the plea of the exactions which he had been forced to levy for the conduct of the war against Teemoor, and accomplished his death. He was beheaded in the month of Safar in the year 815, and his corpse was left unburied. Abu-l-Mahâsin gives him the character of an extravagant, cruel, and voluptuous king.

El-Mansoor 'Abd-el-'Azeez. Farag restored.

El-Musta'een.

El-Musta'een bi-llâh, with the title of El-Melik El-'A'dil Abu-l-Fadl, began his reign well; but he had appointed El-Mahmoodee his Wezeer as a reward for his services, and this powerful and vigorous chief soon obliged him to abdicate, and eventually exiled him to Alexandria, where he passed the remainder of his days.

El-Mu-eiyad Sheykh. Campaigns in Syria.

El-Melik El-Mu-eiyad Abu-n-Nasr Sheykh El-Mahmoodee (originally a Memlook of Barkook's) waged three successful wars in Syria, in the first of which he was guilty of a breach of faith in putting to death the governor of Damascus and part of the garrison of that city, after they had surrendered on promise of safety. He reigned peacefully in Egypt, and his name is recorded as that of a king who studied the happiness of his subjects and favoured the learned, who counted him among their number. But he was avaricious; although we might judge the contrary from his beautiful mosque, and the elegant minarets over the Bâb-Zuweyleh, in Cairo, which are among the chief ornaments of the city.[1]

El-Mudhaffar Ahmad. Edh-Dhâhir Tatar. Es-Sâlih Mohammad. El-Ashraf Barsabây. Expedition to Cyprus.

Three kings followed in rapid succession: El-Mudhaffar Ahmad, a son of El-Mu-eiyad, under two years of age at his accession; Edh-Dhâhir Tatar and his infant son, Es-Sâlih Mohammad, who was deposed by Barsabây Ed-Dukmâkee. This Memlook assumed the title of El-Melik El-Ashraf, and worthily continued the prosperous reign of El-Mu-eiyad. In power and virtue he ranks second only to Barkook among all the kings of this dynasty.[2] He is known in European history by his expedition in 827 against John III., king of Cyprus, who became his vassal; and by the part he took, about seven years later, in the dissensions of the court of Savoy and the government of Cyprus. He ruled for seventeen years, with great clemency, and died in 841. El-'Azeez Yoosuf, his son, was deposed by El-Mansoor Aboo-Sa'eed Jakmak El-'Alâ-ee, a good prince, and a patron of the learned.[3] After a peaceful reign he abdicated at the age of about eighty years in favour of his son, El-Mansoor Abu-s-Sa'âdât 'Othmân, who was overthrown by the intrigues of the Khaleefeh El-Kâïm bi-amri-llâh, and was succeeded by an aged Memlook, El-Ashraf-Abu-n-Nasr Eynâl El-'Alâ-ee En-Nâsiree, followed by his son, El-Mu-eiyad Shihâb-ed-Deen Abu-l-Fet-h Ahmad. Edh-Dhâhir Seyf-ed-Deen-Khóshkadam, a Greek by birth, superseded him, reigning himself for seven years, with equity and benignity; presenting a contrast to the cruelty and oppression of his appointed successor, Edh-Dhâhir Aboo-Sa'eed Bilbây El-'Alâ-ee, which caused the latter's fall and the elevation of the Sultân Aboo-Sa'eed Temerbeg Edh-Dhâhiree, who, in his turn, was deposed to make room for El-Ashraf Kâït Bey, a prince who deserves especial notice for his struggles with the Turks, whereby the conquest of Egypt by that people was deferred for a few years. After a period of quiet which followed his accession, he was alarmed by the victory gained by Mohammad II. over his ally the King of Persia, and posted a considerable force on the frontier of Syria. The successes of the conqueror of Constantinople made him desire to abdicate; but the Emeers prayed him to defend his rights, and he consequently prepared for the war. The death of Mohammad, and the dissensions between Bâyezeed II. and Jem (or Zizim) temporarily relieved him of these apprehensions. The fall of Jem, however, and his arrival at the Egyptian court, implicated Kâït Bey in the quarrel; and on the final overthrow of this prince he made sure of a war with the more fortunate Bâyezeed, and himself began aggressive measures, intercepted the Turkish caravan of Pilgrims, and an ambassador from India who was on his way to Constantinople with presents, and took Tarsus and Adaneh. A remonstrance from Bâyezeed was answered by a successful attack on his Asiatic commander, 'Alâ-ed-Dowleh. In the meantime Tarsus and Adaneh were recovered from him; but the Emeer El-Ezbekee, to whom was entrusted the conduct of all future wars, being despatched against these towns, retook them, defeated an army sent to chastise him, and annexed Karamania. Another force was speedily equipped, and took the field in 893: conditions of peace were refused, and considerable success attended the Turkish arms. El-Ezbekee was, therefore, again ordered to Syria; a Turkish squadron conveying troops was dispersed, and at Tarsus he gave battle. The result was at first unfavourable to the Memlooks, whose commander, however, rallied them under cover of night, and succeeded in surprising and totally defeating the Turks. Long negotiations followed this victory; and at length Kâït Bey, who was always most anxious for peace, ceded the disputed towns of Tarsus and Adaneh, and secured repose during the rest of his days. He died in 901, having designated El-Melik En-Nâsir Abu-s-Sa'âdât Mohammad as his successor. This weak and barbarous king was put to death after four years, during which he was deposed, and Kânsooh, surnamed Khamsameeyeh, and Edh-Dhâhir Abu-n-Nasr Kânsooh were successively installed. The first reigned but eleven days, and the latter abdicated after five months of great difficulty and danger. On the death of En-Nâsir, El-Ashraf Kânsooh Jânbalât was elevated to the throne, but six months sufficed to accomplish his fall, and he was fortunate in preserving his life. The next Sultân, El-Melik El-'A'dil Toomân Bey, was acknowledged both in Egypt and Syria. He, however, was overthrown and killed in a few months.

El-Ghooree.

The Memlooks now compelled Kânsooh El-Ghooree to assume the dangerous dignity, with the title of El-Melik El-Ashraf. This prince very unwillingly yielded. His previous life shows him to have been both virtuous and learned; and he proved himself to be an able ruler. After an unsuccessful expedition against the Portuguese in the East, he reigned in peace until the year 915, when Kurkood, the father of Seleem I., the Turkish Sultân, obtained his protection and assistance. Events similar to those which accompanied the end of Jem followed; and Seleem

[1] Abu-l-Mahâsin. [2] *Ib.* [3] El-Is-hâkee bears similar testimony to the character of this king, and that of Barsabây.

Egypt.

War with Seleem.

availed himself of a pretext to declare war against Egypt. The first reverse which the Egyptians suffered occurred to an army commanded by 'Alá-ed-Dowleh, formerly defeated by Káït Bey, but now in the pay of El-Ghooree. The winter was passed by the latter in preparing energetically for the inevitable struggle, and in the spring he advanced in person. Seleem, on his part, reduced the last place in the hands of the Egyptians in 'Aladowleeyeh, and pretended to march towards Persia; but at the same time he sent to demand of El-Ghooree wherefore he opposed his passage, and commanded in person on the frontier. El-Ghooree replied, that his was merely an army of observation, and that he was desirous of mediating between Seleem and Ismá'eel Sháh. Seleem, however, rapidly advanced, refused to listen to an attempt at negotiation, and was met by El-Ghooree on the plain of Marj-Dábik, near Aleppo. A long and sanguinary battle ensued, and victory declared for neither side, until Kheyr Bey, commanding the right wing, and El-Ghazálee, over the left of the Egyptian army, basely deserted to the enemy with their troops. The centre then gave way and fled in utter confusion, notwithstanding the efforts of the Sultán to rally them. He was trampled to death by his routed cavalry, while (according to some) in the act of prayer. This event took place on the 26th of Regeb 922 (A.D. 1517). With his death Egypt lost her independence. The shattered remains of the army collected in Cairo. Toomán Bey, a nephew of the deceased king, was elected Sultán, and at once determined on every resistance to the conqueror. His general in Syria, El-Ganbardee, disputed the road with Seleem step by step, and Toomán Bey awaited his arrival near Cairo. Between El-Khánkah and the metropolis, at the village of Er-Reydáneeyeh, the opposing armies joined battle, on the 29th of Zu-l-Heggeh. The fall of a favourite general, Sinán Páshá, infuriated the Turks, and the brilliant bravery of the Memlooks availed them not. Immense numbers of them were slain by their enemies in the pursuit, and the survivors reunited in Cairo. El-Ganbardee, however, sacrificed his fame by joining the victor. The Turkish army paused for rest; and time was thus given to Toomán Bey to hire Arabs at a great cost to replenish his thinned ranks. Seleem now passed to the west of Cairo. A night surprise conducted by Toomán failed, but he succeeded in putting to the sword a great many Turks. He fortified himself in the city, and a house-to-house combat ensued, the Memlooks defending every foot with the energy of despair; the citadel fell by assault, and the unfortunate Toomán effected his escape towards Alexandria; but on the way he was taken by Arabs, given up to El-Ganbardee and another, and brought in chains to Seleem, who at first received him with honour, but afterwards falsely accused him of conspiring against him, and, with the cruelty and perfidy characteristic of his race, crucified him over the Báb-Zuweyleh, the place of execution for common malefactors. Thus miserably perished the last independent ruler of Egypt, who possessed the best qualities of his line, and whose noble defence of his kingdom would have secured to him the commiseration of any but a Turk.

Battle of Marj-Dábik, and death of El-Ghooree.

Toomán Bey.

The Turkish conquest.

In reviewing the period during which Egypt was governed by independent Muslim princes, it is necessary to consider the spirit of the times and the people over whom they ruled. They succeeded to the government of countries worn out by incessant warfare, overrun by savage hordes, and debased by the rule of the Lower Empire. Egypt had long struggled against the slavery to which it was condemned, and the history of the last three dynasties of Pharaohs evinces the patriotism which yet animated her people. But the successive tyranny of the Persians, the Greeks, and the Romans appears to have annihilated their nationality; and when the Arabs invaded the country, these causes, combined with religious strife, induced them to afford to the conquerors every assistance in their power. But the changeful rule of the lieutenants, and the troubles of the Khaleefehs, debarred Egypt (excepting during the reigns of some kings of the dynasties of the Benee-Tooloon and the Ikhsheedeeyeh) from profiting by the enlightenment of the race who held the dominion over it, until the conquest by the Fátimees. The Khaleefehs of that dynasty contributed in a great degree to restore to Egypt some portion of its ancient prosperity, and with the House of Eiyoob it attained its greatest military glory under the Muslims; but the edifices erected during the rule of the two dynasties of Memlook kings, the libraries collected in Cairo at that period, and the learned men who then flourished, would point to it as the age in which literature and the arts were cultivated with the most success; a sure evidence of the internal prosperity of any country. This is the more surprising when we consider the state of Syria, which had long before their accession fallen a prey to intestine wars, and the ravages of the Tatars, the Crusaders, and other invaders; and also bear in mind the constitution of their government, in which the more powerful chiefs were constantly aiming at the supreme authority; and the practice of purchasing Memlooks, and rearing them in the households of the great to enable their masters to maintain their ascendancy, augmented the number of these aspirants to the throne. These slaves were, unlike the Bahrees (who were the Turkish Memlooks of the Eiyoobee Sultán, Es-Sálih Negm-ed-Deen), chiefly Circassians, who afterwards composed the Second Dynasty, the Burgee. Many of the Memlook Sultáns rivalled in military achievements the great Saláh-ed-Deen, and even penetrated farther than he in their foreign expeditions. In Cairo are preserved the finest specimens of Arab architecture, almost all dating during the period comprised under the domination of the two Memlook Dynasties: the libraries of the mosques, and private collections of that city, though grievously injured since the Turkish conquest, are, or very recently were, the best and most considerable of those of Egypt or Syria;[1] and, as before remarked, the University El-Azhar is still, owing to the fostering care of these Sultáns, the principal seat of learning of the Eastern world. Some have endeavoured to give a history of Egypt after the European model, with accounts of the state of commerce, taxation, and the like, under the Muslims; but those only who have read the Arab histories of this and other countries can appreciate the general fallacy of these conclusions, and perceive in them that common failing of modern authors, a desire to throw a new light on history, rather than state only as much as the materials warrant.

Turkish Páshás.

It would be tedious and unprofitable to follow the details of Turkish misrule and tyranny which are from this time presented to the student of Egyptian history. Although Seleem destroyed the power of the Memlooks, he thought fit to appoint twenty-four Beys over the military provinces of that number into which he divided Egypt, subject to the supreme control of a Páshá, whose council was formed of seven Turkish chiefs (ójáklees), while one of the Beys held the post of Sheykh el-Beled, or Governor of the Metropolis; an officer who became an object of hatred to the other chiefs.[2] For nearly two centuries the successive Páshás were mostly obeyed; but the ambition of becoming Sheykh el-Beled was the fruitful cause of intrigue and murder. The Memlooks who then held power in Egypt were called the Ghuzz, that being the name of the tribe to which they are said to have at first generally belonged; and they continually bought slaves, of Circassian or Georgian race, to

The Ghuzz.

[1] It should, however, be mentioned that many of the most precious of their contents are plunder brought from the libraries of mosques in Syria, as is proved by seals which they bear.

[2] This system was commenced by Seleem, and completed by his successor.

supply the place of children, for they did not intermarry with natives of Egypt, and women of more northern climates are generally either barren or bear sickly offspring in that country. Thus they lacked the surest source of power; few possessed any family ties; but at the same time the slaves in general were remarkably faithful to their patrons. At the expiration of the period before mentioned, the Beys gradually increased in power, until the authority of the Páshá was almost nominal, and the government became a military oligarchy:[1] this brings us to the rise of the celebrated 'Alee Bey. He was created Sheykh el-Beled in the year 1177; but, having revenged himself on an old enemy who had assassinated 'Alee's master, to whom he owed his elevation to the rank of Bey, he shortly after fled to Syria, and took refuge with the governor of Jerusalem, and thence went to Acre, where the Sheykh Dháhir became his friend; and that same year he returned to Cairo in his former capacity of Sheykh el-Beled. In 1179 his enemies again compelled him to flee, and he betook himself this time to El-Yemen, once more to return to Egypt; after which he gained increased power. His favourite Memlook, Mohammad Aboo-Dhahab, proved ungrateful, and, while enjoying the highest power, entered into a conspiracy against his life; but after receiving the presents of the hostile Beys, he denounced them to his master, who would not listen to warnings of his meditated treachery.

'Alee Bey.

In the year 1182, the Porte demanded the assistance of 'Alee Bey in the Russian war; an order which he was about to obey, when he was apprised of the departure of a messenger with a firmán demanding his head, he having been falsely accused at Constantinople of intending to aid the Russians and throw off his allegiance. He caused the bearer of this order to be waylaid and put to death, and having possessed himself of the firmán, he convened the Beys, showed them the document, and aided by those of his own household,[2] persuaded the council to expel the Páshá, and declare Egypt independent. The Sheykh Dháhir took part in this rebellion, and the Páshá of Damascus was beaten by him between Mount Lebanon and Tiberias. A period of good but vigorous government and of tranquillity followed these events in Egypt, notwithstanding the very heavy imposts levied for the replenishment of the treasury; and 'Alee's generals gained for him extended power abroad. Mohammad Aboo-Dhahab was despatched to Arabia, and entered Mekkeh, where the Shereef was deposed, and another Bey traversed the eastern shores of the Red Sea. After the expedition to Arabia, Mohammad Bey marched into Syria to assist the Sheykh Dháhir against the Porte, and the co-operation of the Russians was demanded. A successful campaign terminated before the walls of Damascus, the siege of which was abandoned when nearly brought to a close, and Mohammad Bey returned with large forces to Egypt. This man, loaded with benefits by his patron, now openly rebelled; and being joined by 'Alee's enemies, at the head of whom was Ismá'eel, chief of the guard (who was sent against him and went over to his side), he advanced on Cairo, and 'Alee escaped to his steady ally, Sheykh Dháhir, the Prince of Acre. These events took place in the year 1186. Mohammad Bey was then declared Sheykh el-Beled. 'Alee Bey in the meanwhile, in conjunction with his ally, gained various advantages in Syria, and, on the information that his return was desired in Egypt, he collected a small force, assisted by Sheykh Dháhir and a Russian squadron, and determined on attempting to recover his power. He, however, fell into an ambuscade near Es-Sáliheeyeh, and was wounded by one of his Memlooks named Murád (afterwards Murád Bey),[3] carried to the citadel, and poisoned by Mohammad Bey. Thus terminated the career of the famous 'Alee Bey, a man whose energy, talents, and ambition bear a strong resemblance to those of the late viceroy Mohammad 'Alee.

Egypt declared independent.

Mohammad Bey Aboo-Dhabab continued Sheykh el-Beled, tendered his allegiance to the Porte, and was invested with the pashalic. He then entered Syria, and severely chastised Sheykh Dháhir, taking Gaza, Joppa, and Acre itself. Joppa was taken by assault, and suffered a massacre of its inhabitants, and Acre was pillaged. At the latter place the Páshá suddenly died. His mosque in Cairo is the latest fine specimen of Arab architecture, and is not unworthy of its better days.

Mohammad Bey.

The chief competitors for power were now Ismá'eel, Ibráheem, and Murád, the first of whom was speedily expelled, the contest continuing between the two latter Beys. Ibráheem at length succeeded in causing himself to be proclaimed Sheykh el-Beled, and Murád contented himself with the office of Emeer el-Hagg, or chief of the pilgrims; but this arrangement was not destined to be of long continuance; a violent quarrel resulted in a recourse to arms, and that again in a peace of three years' duration, during which the two Beys held an equal sway. In the year 1200 the Porte despatched Hasan Capitan (properly Kapoodán) Páshá (or High Admiral) with a Turkish force, to reduce the turbulent Memlooks to obedience, and to claim the annual tribute. Murád Bey was defeated at Er-Rahmáneeyeh, and the Turks advanced to Cairo, desolating the country, and acting according to their almost invariable practice on such occasions. The metropolis opened its gates to Hasan Páshá, who determined on pursuing the Beys to Upper Egypt, whither he despatched a large portion of his army, and a sanguinary conflict took place. But a war with Russia recalled this commander to Constantinople. Ismá'eel was again created Sheykh el-Beled, and he held that post until the terrible plague of the year 1205, in which he perished, and hence it is commonly called the "Plague of Ismá'eel." His death caused the return of Ibráheem and Murád; and eight years after intelligence of the arrival at Alexandria of a French army of 36,000 men, commanded by General Bonaparte, united these chiefs in a common cause.

Ibráheem Bey.

Ismá'eel Bey.

On the 18th May 1798 (A.H. 1212), this expedition, consisting of 13 sail of the line, 6 frigates, and 12 vessels of a smaller size, sailed from Toulon, and made the coast of Egypt on the 1st July. The troops were landed near Alexandria, and the city fell by assault on the 5th of that month. The French conquest and occupation of Egypt belong to European history; a recapitulation of the principal events of the period will therefore suffice in this place. The Memlooks affected to despise their antagonist, and hastened to chastise him: at Shibirrees they attacked the French, and were repulsed; but, nothing discouraged, they collected all their forces, exceeding 60,000 men, under the command of Murád, and entrenched themselves at Embábeh, opposite Cairo. Here was fought the battle which has been dignified with the name of that of the Pyramids. European tactics completely bewildered the Memlooks, their famous cavalry was received on the bayonets of the French squares, a galling fire of grape and musketry mowed down their ranks, and of this great army only about 2500 horse escaped with Murád Bey, while 15,000 men of all arms fell on the field of battle. Having made himself master of Cairo, Bonaparte despatched General Desaix to effect the conquest of Upper Egypt, and the success of the Eastern expedition seemed secured. But, ten days after the

The French invasion.

Battle of the Pyramids.

[1] See the *Englishwoman in Egypt*, vol. i., p. 229–231.

[2] 'Alee Bey had, ever since his attainment to the post of Sheykh el-Beled, endeavoured to appoint his own creatures to all places of dignity and trust; he had also greatly increased the number of his Memlooks, to the amount of 6000, and created eighteen of them Beys.

[3] This event is variously related. Marcel states that he was victorious over the advanced guard of Mohammad Bey, but defeated and wounded in a battle with the main body; he places the scene of the encounter at the same place, near Es-Sáliheeyeh.

Egypt. Battle of the Nile. victory of Embâbeh, the battle of the Nile annihilated the French fleet in Aboo-Keer Bay, and most materially influenced the future conduct of the war. On this point, Napoleon himself says, "La perte de la bataille d'Aboukir eut une grande influence sur les affaires d'Égypte et même sur celles du monde; la flotte Française sauvée, l'expédition de Syrie n'éprouvait point d'obstacles, l'artillerie de siége se transportait sûrement et facilement au-delà du désert, et Saint-Jean-d'Acre n'arrêtait point l'armée Française. La flotte Française détruite, le divan s'enhardit à déclarer la guerre à la France. L'armée perdit un grand appui, sa position en Égypte changea totalement, et Napoléon dut renoncer à l'espoir d'asseoir à jamais la puissance Française dans l'Occident par les résultats de l'expédition d'Égypte."[1] The disastrous expedition into Syria, undertaken for the purpose of frustrating the efforts of Sir Sydney Smith before Alexandria, and of Jezzâr Páshá, who was advancing from Acre, still further obscured Napoleon's prospects in the East, and the victory soon after obtained by him over the Ottoman army at Aboo-Keer, the second defeat of Murád Bey, and various successes over the Turks, enabled the French general Kléber (Napoleon having left for Europe after the first of these events) to set on foot negotiations for an honourable evacuation of the country. But when the convention was already signed, and the French were about to quit Cairo, Lord Keith signified to Kléber that Great Britain would not consent to the terms of the treaty; and although this refusal was afterwards rescinded, Kléber considered that the withdrawal came too late: he totally defeated 70,000 men under the Grand Vezeer at Heliopolis, and returned to Cairo to quell an insurrection of the inhabitants. This distinguished officer was about this time assassinated in the garden of his palace by a fanatic, who was impaled in the great square (then a lake) called the Ezbekeeyeh, in Cairo, and miserably lingered for the space of three days before death put an end to his sufferings. Under Kléber's administration, Egypt began to resume its former prosperity: by his conciliatory and good government, much prejudice against the French was overcome; by ceding a part of Upper Egypt to Murád, he gained the good will of that chief, who gave him no cause to regret this politic step; while under his auspices the "savans" of the Institute collected the valuable mass of information embodied in the "Great French Work."

On the death of Kléber, General Menou succeeded to the command, and although he afterwards conducted the defence of the country with much valour, yet, to his injudicious administration, and his want of military talent, we must mainly ascribe the determination of the British government to attempt the expulsion of the French from Egypt, and the rapid success of the campaign that ensued. On the

British expedition. 2d of March 1801 an army under Sir Ralph Abercromby arrived in Aboo-Keer Bay and made good a landing in the face of a well-disposed French force, which offered every possible resistance. The memorable battle of Alexandria, in which Abercromby fell, decided the fate of the war. A bold march, executed with talent, effected the capitulation of Cairo; Alexandria surrendered on the 1st of September, and the French sailed from the shores of Egypt in the course of that month.[2] General Hutchinson had taken the command of the English expedition, afterwards reinforced by a detachment from India under General Baird; and the army of the Grand Vezeer, and that of the Capitan-Páshá, with the troops of Ibráheem Bey (Murád having died of the plague), had co-operated in the measures which led to the evacuation of the country by Menou.[3]

Origin of Mohammad 'Alee. The history now requires that we should mention the early career of a man who subsequently ruled the destinies of Egypt for a period of nearly forty years. The late viceroy of Egypt, Mohammad 'Alee Páshá, was born in the year of the Flight 1182 (A.D. 1768–9) at Cavalla, a small seaport town of Albania. On the death of his father, in early life, he was brought up in the house of the governor of the town, who, as a reward for military prowess, gave him his daughter in marriage. By her he had, it is said, his three eldest sons, Ibráheem,[4] Toosoon, and Ismá'eel. Having attained the rank of bûluk-báshee (or head of a body of infantry), he became a dealer in tobacco, until, in his thirty-third year, he was despatched with his patron's son, 'Alee Agha, and 300 men, the contingent furnished by his native place, with the Turkish expedition against the French in Egypt; and soon after his arrival in that country he succeeded, on the return of 'Alee Agha, to the command, with the nominal rank of beeñ-báshee (or chief of a thousand men).

Soon after the evacuation of Egypt by the French, that unfortunate country became the scene of more severe troubles, in consequence of the unwarrantable attempts of the Turks to destroy the power of the Ghuzz. In defiance of promises to the English government, orders were transmitted from Constantinople to Hoseyn Páshá, the Turkish High Admiral, to ensnare and put to death the principal Beys. Invited to an entertainment, they were, according to the Egyptian contemporary historian El-Gabartee,[5] attacked on board the flag-ship; Sir Robert Wilson and M. Mengin, however, state that they were fired on, in open boats, in the bay of Aboo-Keer. They offered a heroic resistance, but were overpowered and made prisoners, while Mohammad Bey El-Menfookh, 'Osmân[6] Bey Et-Tamburgee, 'Osmân Bey El-Ashtar, Mohammad Bey El-Hasanee, Murád Bey the Younger, and Ibráheem Kikhya Es-Sennâree (a black), were among the killed. Some, including the afterwards-celebrated 'Osmân Bey El-Bardeesee, escaped in a boat, and sought refuge with the English, who at that time occupied Alexandria. General Hutchinson, informed of this treachery, immediately assumed threatening measures against the Turks, and in consequence, the killed, wounded, and prisoners were given up to him. Such was the commencement of the disastrous struggle between the Memlooks and the Turks.

Khusruf Pasha. Mohammad Khusruf was the first Páshá after the expulsion of the French. The form of government, however, was not the same as that before the French invasion; for the Ghuzz were not reinstated. The Páshá, and through him, the Sultân, endeavoured on several occasions either to ensnare them, or to beguile them into submission; but their efforts failing, Mohammad Khusruf took the field, and a Turkish detachment 14,000 strong despatched against them to Demenhoor, whither they had descended from Upper Egypt, was defeated by a small force under El-Elfee.[7] Their ammunition and guns fell into the hands of the Memlooks.

Departure of the British. In March 1803 the British evacuated Alexandria, and Mohammad Bey El-Elfee accompanied them to England to consult respecting the means to be adopted for restoring the former power of the Ghuzz. About six weeks after, the Arnaoot (or Albanian) soldiers in the service of Khusruf tumultuously demanded their pay, and surrounded the house

[1] Napoleon, *Memoires*, t. ii.

[2] Very many of the French had either married Muslim females, or bought concubine slaves of the same faith, whom, on their departure, they left behind them; and these unfortunates were forthwith tied up in sacks and drowned.

[3] Sir R. Wilson's *History of the British Expedition.*

[4] Ibráheem is, however, believed by many, or most, to have been the wife's son by a former husband.

[5] The MS. annals of El-Gabartee have furnished the materials for this narrative of the times of Mohammad 'Alee, until the month of Gumáda-t-Táníyeh, A.H. 1220 (A.D. 1805), when they terminate.

[6] Correctly 'Othmán, but commonly pronounced 'Osmân.

[7] Mengin says that El-Elfee withdrew his force leaving El-Bardeesee with 800 men to meet the enemy.

Egypt.

of the Defterdâr, who in vain appealed to the Páshá to satisfy their claims. The latter opened fire from the artillery of his palace on the insurgent soldiery in the house of the Defterdâr, across the Ezbekeeyeh. The citizens of Cairo, accustomed to such occurrences, immediately closed their shops, and the doors of the several quarters, and every man who possessed any weapon armed himself. The tumult continued all the day, and the next morning a body of troops sent out by the Páshá failed to quell it. Táhir, the commander of the Albanians, then repaired to the citadel, gained admittance through an embrasure, and having obtained possession of it, began to cannonade the Páshá over the roofs of the intervening houses, and then descended with guns to the Ezbekeeyeh, and laid close siege to the palace. On the following day, Mohammad Khusruf made good his escape with his women and servants and his regular troops, and fled to Damietta by the river. This revolt marks the commencement of the rise of Mohammad 'Alee to power in Egypt, and of the breach between the Arnaoots and Turks which ultimately led to the expulsion of the latter.

Táhir Páshá.

Táhir Páshá assumed the government, but in twenty-three days he met with his death from exactly the same cause as that of the overthrow of his predecessor. He refused the pay of certain of the Turkish troops, and was immediately assassinated. A desperate conflict ensued between the Albanians and Turks; and the palace was set on fire and plundered. The masters of Egypt were now split into these two factions, animated with the fiercest animosity against each other. Mohammad 'Alee became the head of the former, but his party was the weaker, and he therefore entered into an alliance with Ibráheem Bey, and 'Osmán Bey El-Bardeesee. A certain Ahmad Páshá, who was about to proceed to a province in Arabia, of which he had been appointed governor, was raised to the important post of Páshá of Egypt, through the influence of the Turks, and the favour of the Sheykhs; but Mohammad 'Alee, who with his Albanians held the citadel, refused to assent to their choice; the Memlooks moved over from El-Geezeh, and Ahmad Páshá betook himself to the mosque of Ez-Záhir,[1] which the French had converted into a fortress. He was compelled to surrender by the Albanians; the two chiefs of the Turks who killed Táhir Páshá were taken with him and put to death, and he himself was detained a prisoner. In consequence of the alliance between Mohammad 'Alee and El-Bardeesee, the Albanians gave the citadel over to the Memlooks; and soon after, these allies marched against Khusruf Páshá, who having been joined by a considerable body of Turks, and being in possession of Damietta, was enabled to offer an obstinate resistance. After much loss on both sides, he was taken prisoner and brought to Cairo; but he was treated with much respect. The victorious soldiery sacked the town of Damietta, and were guilty of the barbarities usual with them on such occasions.

'Alee Páshá.

A few days later, 'Alee Páshá El-Tarábulusee[2] landed at Alexandria with an imperial firmán constituting him Páshá of Egypt, and threatened the Beys, who now were virtual masters of Upper Egypt, as well as of the capital and nearly the whole of Lower Egypt. Mohammad 'Alee and El-Bardeesee therefore descended to Rosetta, which had fallen into the hands of a brother of 'Alee Páshá, and having recovered the town and captured its commander, El-Bardeesee purposed to proceed against Alexandria; but the troops required arrears of pay which it was not in his power to give, and the Páshá had cut the dyke between the Lakes of Aboo-Keer and Mareotis, thus rendering the approach to Alexandria more difficult. El-Bardeesee and Mohammad 'Alee therefore returned to Cairo. The troubles of Egypt were now increased by an insufficient inundation, and great scarcity prevailed, aggravated by the exorbitant taxation to which the Beys were compelled to resort in order to raise money to pay the troops; while murder and rapine prevailed to a frightful extent in the capital, the riotous soldiery being under little or no control. In the meantime, 'Alee Páshá, who had been behaving in an outrageous manner towards the Franks in Alexandria, received a khatt-i-shereef from the Sultán, which he sent by his secretary to Cairo. It announced that the Beys should live peaceably in Egypt, with an annual pension, each, of fifteen purses[3] and other privileges, but that the government should be in the hands of the Páshá. To this the Beys assented, but with considerable misgivings; for they had intercepted letters from 'Alee to the Albanians, endeavouring to alienate them from their side to his own; to these, deceptive answers were returned, and he was induced by them to advance towards Cairo, at the head of 2500 men. The forces of the Beys, with the Albanians, encamped near him at Shalakán, and he fell back on a place called Zufeyteh. They next seized his boats conveying soldiers, servants, and his ammunition and baggage; and, following him, they demanded wherefore he brought with him so numerous a body of men, in opposition to usage and to their previous warning. Finding they would not allow his troops to advance, forbidden himself to retreat with them to Alexandria, and being surrounded by the enemy, he would have hazarded a battle, but his men refused to fight. He therefore repaired to the camp of the Beys, and his army was compelled to retire to Syria. In the hands of the Beys, 'Alee Páshá again attempted treachery. A horseman was seen to leave his tent one night at full gallop; he was the bearer of a letter to 'Osmán Bey Hasan, the governor of Kinè. This offered a fair pretext to the Memlooks to rid themselves of a man whose antecedents, and his present conduct, proved him to be a perfidious tyrant. He was sent under a guard of forty-five men towards the Syrian frontier; and about a week after, news was received that in a skirmish with some of his own soldiers he had fallen mortally wounded.

The death of 'Alee Páshá produced only temporary tranquillity; in a few days the return of Mohammad Bey El-Elfee (called the Great or Elder), from England, was the signal for fresh disturbances, which, by splitting the Ghuzz into two parties, accelerated their final overthrow. The jealousy which existed between El-Elfee and the other most powerful Bey, El-Bardeesee, has been before mentioned. The latter was now supreme among the Ghuzz, and this fact considerably heightened their old enmity. While the guns of the citadel, those at Masr El-'Ateekah, and even those of the palace of El-Bardeesee, were thrice fired in honour of El-Elfee, preparations were immediately commenced to oppose him. His partisans were collected opposite Cairo, and El-Elfee the Younger held El-Geezeh; but treachery was among them; Hoseyn Bey El-Elfee was assassinated by emissaries of El-Bardeesee, and Mohammad 'Alee, with his Albanians, gained possession of El-Geezeh, which was, as usual, given over to the troops to pillage. In the meanwhile El-Elfee the Great embarked at Rosetta; and not apprehending opposition, was on his way to Cairo, when a little south of the town of Manoof he encountered a party of Albanians, and with difficulty made his escape. He gained the eastern branch of the Nile, but the river had become dangerous, and he fled to the desert. There he had several hair-breadth escapes, and at last secreted himself among a tribe of Arabs at Rás-el-Wádee. A change in the fortune of El-Bardeesee, however, favoured his plans for the future. That chief, in order to satisfy the demands of the Albanians for their pay, gave orders to levy heavy contributions from the citizens of Cairo; and this new oppres-

Egypt.

sion roused them to rebellion. The Albanians, alarmed for their safety, assured the populace that they would not allow the order to be executed; and Mohammad 'Alee himself caused a proclamation to be made to that effect. Thus the Albanians became the favourites of the people, and took advantage of their opportunity. Three days later they beset the house of the aged Ibráheem Bey, and that of El-Bardeesee, both of whom effected their escape with considerable difficulty. The Memlooks in the citadel directed a fire of shot and shell on the houses of the Albanians which were situated in the Ezbekeeyeh; but on hearing of the flight of their chiefs, they evacuated the place; and Mohammad 'Alee, on gaining possession of it, once more proclaimed Mohammad Khusruf Páshá of Egypt. For one day and a half he enjoyed the title; the friends of the late Táhir Páshá then accomplished his second degradation,[1] and Cairo was again the scene of terrible enormities, the Albanians revelling in the houses of the Memlook chiefs, whose hareems met with no mercy at their hands. These events were the signal for the reappearance of El-Elfee.

Khursheed Páshá.

The Albanians now invited Ahmad Páshá Khursheed to assume the reins of government, and he without delay proceeded from Alexandria to Cairo. The forces of the partisans of El-Bardeesee were ravaging the country a few miles south of the capital, and intercepting the supplies of corn by the river: a little later they passed to the north of Cairo, and successively took Bilbeys and Kalyoob, plundering the villages, destroying the crops, and slaughtering the herds of the inhabitants. Cairo was itself in a state of tumult, suffering severely from a scarcity of grain, and the heavy exactions of the Páshá to meet the demands of his turbulent troops, at that time augmented by a Turkish detachment. The shops were closed, and the unfortunate people assembled in great crowds, crying Yá Lateef! Yá Lateef! "O gracious [God]!" El-Elfee and 'Osmán Bey Hasan had professed allegiance to the Páshá; but they soon after declared against him, and they were now approaching from the south; and having repulsed Mohammad 'Alee, they took the two fortresses of Turà. These Mohammad 'Alee speedily retook by night with 4000 infantry and cavalry; but the enterprise was only partially successful. On the following day the other Memlooks north of the metropolis actually penetrated into the suburbs; but a few days later were defeated in a battle fought at Shubrà, with heavy loss on both sides. This reverse in a measure united the two great Memlook parties, though their chiefs remained at enmity. El-Bardeesee passed to the south of Cairo, and the Ghuzz gradually retreated towards Upper Egypt. Thither the Páshá despatched three successive expeditions (one of which was commanded by Mohammad 'Alee), and many battles were fought, but without decisive result.

Misery of the people of Cairo.

At this period another calamity befel Egypt; about 3000 Delees arrived in Cairo from Syria. These troops had been sent for by Khursheed in order to strengthen himself against the Albanians; and the events of this portion of the history afford sad proof of their ferocity and brutal enormities, in which they far exceeded the ordinary Turkish soldiers and even the Albanians. Their arrival immediately recalled Mohammad 'Alee and his party from the war, and instead of aiding Khursheed, was the proximate cause of his overthrow.

Cairo was ripe for revolt; the Páshá was hated for his tyranny and extortion, and execrated for the deeds of his troops, especially those of the Delees: the Sheykhs enjoined the people to close their shops, and the soldiers clamoured for pay. At this juncture a firmán arrived from Constantinople conferring on Mohammad 'Alee the pashalic of Jiddeh; but the occurrences of a few days raised him to that of Egypt.

On the 12th of Safar A.H. 1220 (May 1805) the Sheykhs, with an immense concourse of the inhabitants, assembled in the house of the Kádee; and the 'Ulamà, amid the prayers and cries of the people, wrote a full statement of the heavy wrongs which they had endured under the administration of the Páshá. The 'Ulamà, in answer, were desired to go to the citadel; but they were apprised of treachery; and on the following day, having held another council at the house of the Kádee, they proceeded to Mohammad 'Alee, and informed him that the people would no longer submit to Khursheed. "Then whom will ye have?" said he. "We will have *thee*," they replied, "to govern us according to the laws; for we see in thy countenance that thou art possessed of justice and goodness." Mohammad 'Alee seemed to hesitate, and then complied, and was at once invested. On this, a bloody struggle commenced between the two Páshás: Cairo had before experienced such conflicts in the streets and over the house-tops, but none so severe as this. Khursheed, being informed by a messenger of the insurrection, immediately laid in stores of provisions and ammunition, and prepared to stand a siege in the citadel. Two chiefs of the Albanians joined his party, but many of his soldiers deserted. Mohammad 'Alee's great strength lay in the devotion of the citizens of Cairo, who looked on him as their future deliverer from their afflictions; and great numbers armed themselves, advising constantly with Mohammad 'Alee, having the seyyid 'Omar and the Sheykhs at their head, and guarding the town at night. On the 19th of the same month, Mohammad 'Alee besieged Khursheed. Retrenchments were raised, and the lofty minaret of the mosque of the Sultán Hasan was used as a battery from whence to fire on the citadel; while guns were also posted on the mountain in its rear. After the siege had continued many days, Khursheed gave orders to cannonade and bombard the town; and for six days his commands were executed with little interruption, the citadel itself also lying between two fires. Mohammad 'Alee's position at this time was very critical: his troops became mutinous for their pay; the Siláhdár, who had commanded one of the expeditions against the Ghuzz, advanced to the relief of Khursheed; and the latter ordered the Delees to march to his assistance. The firing ceased on the Friday, but recommenced on the eve of Saturday, and lasted until the next Friday. On the day following, news came of the arrival at Alexandria of a messenger from Constantinople. The ensuing night in Cairo presented a curious spectacle: many of the inhabitants gave way to rejoicing, in the hope that this envoy would put an end to their miseries, and fired off their weapons as they paraded the streets with bands of music. The Siláhdár, imagining the noise to be a fray, marched in haste towards the citadel; while its garrison sallied forth, and commenced throwing up retrenchments in the quarter of 'Arab-el-Yesár, but were repulsed by the armed inhabitants and the soldiers stationed there; and during all this time, the cannonade and bombardment from the citadel, and on it from the batteries on the mountain, continued unabated.

Khursheed besieged in the citadel. He cannonades and bombards Cairo.

The envoy brought a firmán confirming Mohammad 'Alee, and ordering Khursheed to repair to Alexandria, there to await further orders; but this he refused to do, on the ground that he had been appointed by a khatt-i-shereef. The firing ceased on the following day, but the troubles of the people were rather increased than assuaged; murders and robberies were daily committed by the soldiery, the shops were all shut, and some of the streets barricaded.

Mohammad 'Alee confirmed by the Porte.

[1] Khusruf Páshá has since filled with credit several of the highest offices at Constantinople. He died on the 1st of February in this year, 1855. He was a bigot of the old school, strongly opposed to the influences of western civilization, and consequently to the assistance of France and England in the present war.

Egypt.

While these scenes were being enacted, El-Elfee was besieging Demenhoor, and the other Beys were returning towards Cairo, Khursheed having called them to his assistance.

Soon after this, a squadron under the command of the Turkish High Admiral arrived in Aboo-Keer Bay, with despatches confirmatory of the firmân brought by the former envoy, and authorizing Mohammad 'Alee to continue to discharge the functions of governor for the present. Khursheed at first refused to yield; but at length, on condition that his troops should be paid, he evacuated the citadel, and embarked for Rosetta.

Mohammad 'Alee now possessed the title of Governor of Egypt, but beyond the walls of Cairo his authority was everywhere disputed by the Beys, who were joined by the army of the Silâhdâr of Khursheed; and many Albanians deserted from his ranks. To replenish his empty coffers he was also compelled to levy exactions, principally from the Copts. An attempt was made to ensnare certain of the Beys, who were encamped north of the metropolis. On the 17th of August 1805, the dam of the canal of Cairo was to be cut, and some chiefs of Mohammad 'Alee's party wrote, informing them that he would go forth early on that morning with most of his troops to witness the ceremony, inviting them to enter and seize the city; and, to deceive them, stipulating for a certain sum of money as their reward. The dam, however, was cut early in the preceding night, without any ceremony. On the following morning, these Beys, with their Memlooks, a very numerous body, broke open the gate of the suburb El-Hoseyneeyeh, and gained admittance into the city from the north, through the gate called Bâb-el-Futooh. They marched along the principal street for some distance, with kettle-drums behind each company, and were received with apparent joy by the citizens. At the mosque called the Ashrafeeyeh they separated, one party proceeding to the Azhar and the houses of certain Sheykhs, and the other continuing along the main street, and through the gate called Bâb-Zuweyleh, where they turned up towards the citadel. Here they were fired on by some soldiers from the houses; and with this signal a terrible massacre commenced. Falling back towards their companions, they found the bye-streets closed; and in that part of the main thoroughfare called Beyn-el-Kasreyn, they were suddenly placed between two fires. Thus shut up in a narrow street, some sought refuge in the collegiate mosque El-Barkookeeyeh, while the remainder fought their way through their enemies, and escaped over the city wall with the loss of their horses. Two Memlooks had, in the mean time, succeeded, by great exertions, in giving the alarm to their comrades in the quarter of the Azhar, who escaped by the eastern gate called Bâb-el-Ghureiyib. A horrible fate awaited those who had shut themselves up in the Barkookeeyeh: they begged for quarter and surrendered, were immediately stripped nearly naked, and about fifty were slaughtered on the spot; and about the same number were dragged away, with every brutal aggravation of their pitiful condition, to Mohammad 'Alee. Among them were four Beys, one of whom, driven to madness by Mohammad 'Alee's mockery, asked for a drink of water; his hands were untied, that he might take the bottle, but he snatched a dagger from one of the soldiers, and rushed at the Pâshâ, and fell, covered with wounds. The wretched captives were then chained, and left in the court of the Pâshâ's house; and on the following morning the heads of their comrades who had perished the day before were skinned, and stuffed with straw, before their eyes. One Bey and two others paid their ransom, and were released; the rest, without exception, were tortured and put to death in the course of the ensuing night. Eighty-three heads (many of them those of Frenchmen and Albanians) were stuffed, and sent to Constantinople, with a boast that the Memlook chiefs were utterly destroyed. Thus ended Mohammad 'Alee's first massacre of his too confiding enemies.

Egypt.

The Beys, after this, appear to have despaired of regaining their ascendancy; most of them retreated to Upper Egypt, and an attempt at compromise failed. El-Elfee offered his submission, on the condition of the cession of the Feiyoom and other provinces; but this was refused, and that chief gained two successive victories over the Pâshâ's troops, many of whom deserted to him.

At length, in consequence of the remonstrances of the English, and a promise made by El-Elfee of 1500 purses, the Porte consented to reinstate the twenty-four Beys, and to place El-Elfee at their head; but this measure met with the opposition of Mohammad 'Alee, and the determined resistance of the majority of the Memlooks, who, rather than have El-Elfee at their head, preferred their present condition; for the enmity of El-Bardeesee had not subsided, and he commanded the voice of most of the other Beys. In pursuance of the above plan, a squadron under Sâlih Pâshâ, shortly before appointed High Admiral, arrived at Alexandria on the 1st of July 1806, with 3000 regular troops, and a successor to Mohammad 'Alee, who was to receive the pashalic of Salonica. This wily chief professed his willingness to obey the commands of the Porte; but stated that his troops, to whom he owed a vast sum of money, opposed his departure. He induced the 'Ulamà to sign a letter, praying the Sultân to revoke the command for reinstating the Beys; persuaded the chiefs of the Albanian troops to swear allegiance to him, and sent 2000 purses contributed by them to Constantinople. El-Elfee was at that time besieging Demenhoor, and he gained a signal victory over the Pâshâ's troops; but the dissensions of the Beys destroyed their last chance of a return to power. El-Elfee and his partisans were unable to pay the sum promised to the Porte; Sâlih Pâshâ received plenipotentiary powers from Constantinople, in consequence of the letter from the 'Ulamà; and, on the condition of Mohammad 'Alee's paying 4000 purses to the Porte, it was decided that he should continue in his post, and the reinstatement of the Beys was abandoned. Fortune continued to favour the Pâshâ. In the following month, El-Bardeesee died, aged forty-eight years; and, soon after, a scarcity of provisions excited the troops of El-Elfee to revolt. That Bey very reluctantly raised the siege of Demenhoor, being in daily expectation of the arrival of an English army; and at the village of Shubra-ment he was attacked by a sudden illness, and died on the 30th of January 1807, aged 55 years. Thus was the Pâshâ relieved of his two most formidable enemies; and, shortly after, he defeated Shâheen Bey, with the loss, to the latter, of his artillery and baggage, and 300 men killed or taken prisoners.

The British expedition of 1807.

On the 17th of March 1807, a British fleet appeared off Alexandria, having on board nearly 5000 troops, under the command of General Fraser; and the place, being disaffected towards Mohammad 'Alee, opened its gates to them. Here they first heard of the death of El-Elfee, upon whose cooperation they had founded their chief hopes of success; and they immediately despatched messengers to his successor, and to the other Beys, inviting them to Alexandria. The British resident, Major Misset, having represented the importance of taking Rosetta and Er-Rahmâneeyeh, to secure supplies for Alexandria, General Fraser, with the concurrence of the Admiral, Sir John Duckworth, detached the 31st regiment and the Chasseurs Britanniques, under Major-General Wauchope and Brigadier-General Meade, on this service; and these troops entered Rosetta without encountering any opposition; but as soon as they had dispersed among the narrow streets, the garrison opened a deadly fire on them from the latticed windows and the roofs of the houses. They effected a retreat on Aboo-Keer and Alexandria, after a very heavy loss of 185 killed and 262 wounded; General Wauchope and three officers being among the

former, and General Meade and seventeen officers among the latter. The heads of the slain were fixed on stakes, on each side of the road crossing the Ezbekeeyeh in Cairo.

Mohammad 'Alee, meanwhile, was conducting an expedition against the Beys in Upper Egypt, and he had defeated them near Asyoot, when he heard of the arrival of the British. In great alarm lest the Beys should join them, especially as they were far north of his position, he immediately sent messengers to his rivals, promising to comply with all their demands, if they should join in expelling the invaders; and this proposal being agreed to, both armies marched towards Cairo on opposite sides of the river.

To return to the unfortunate British expedition. The possession of Rosetta being deemed indispensable, Brigadier-General Stewart and Colonel Oswald were despatched thither, with 2500 men. For 13 days a cannonade of that town was continued without effect; and on the 20th of April, news having come in from the advanced guard at El-Hamâd of large reinforcements to the besieged, General Stewart was compelled to retreat; and a dragoon was despatched to Major Macleod, commanding at El-Hamâd, with orders to fall back. The messenger, however, was unable to penetrate to the spot; and the advanced guard—consisting of a detachment of the 71st, two companies of the 78th, one of the 35th, and De Rolles' regiment, with a picquet of dragoons, the whole mustering 733 men—was surrounded, and after a gallant resistance, the survivors, who had expended all their ammunition, became prisoners of war. General Stewart regained Alexandria with the remainder of his force, having lost, in killed, wounded, and missing, nearly 900 men. Some hundreds of British heads were now exposed on stakes in Cairo, and the prisoners were marched between these mutilated remains of their countrymen.

The Beys became divided in their wishes; one party being desirous of co-operating with the British, the other, with the Pâshâ. These delays proved ruinous to their cause; and General Fraser, despairing of their assistance, evacuated Alexandria on the 14th of September.[1] From that date to the spring of 1811, the Beys from time to time relinquished certain of their demands; the Pâshâ on his part granted them what before had been withheld; the province of the Feiyoom, and part of those of El-Geezeh and Benee-Suweyf, were ceded to Shâheen; and a great portion of the Sa'eed, on the condition of paying the land-tax, to the others. Many of them took up their abode in Cairo, but tranquillity was not secured; several times they met the Pâshâ's forces in battle, and once gained a signal victory. Early in the year 1811, the preparations for an expedition against the Wahhâbees in Arabia being complete, all the Memlook Beys then in Cairo were invited to the ceremony of investing Mohammad 'Alee's favourite son, Toosoon, with a pelisse, and the command of the army. As on the former occasion, the unfortunate Memlooks fell into the snare. On the 1st of March, Shâheen Bey, and the other chiefs (one only excepted), repaired with their retinues to the citadel, and were courteously received by the Pâshâ. Having partaken of coffee, they formed in procession, and, preceded and followed by the Pâshâ's troops, slowly descended the steep and narrow road leading to the great gate of the citadel; but as soon as the Memlooks arrived at this gate, it was suddenly closed before them. The last of those who made their exit before the gate was shut were Sâlih Koosh and his Albanians. To these troops their chief now made known the Pâshâ's orders to massacre all the Memlooks within the citadel; therefore, having returned by another way, they gained the summits of the walls and houses that hem in the road in which the Memlooks were incarcerated, and some stationed themselves upon the eminences of the rock through which that road is partly cut. Thus securely placed, they commenced a heavy fire on their defenceless victims; and immediately the troops who closed the procession, and who had the advantage of higher ground, followed their example. Of the betrayed chiefs, many were laid low in a few moments; some, dismounting, and throwing off their outer robes, vainly sought, sword in hand, to return, and escape by some other gate. The few who regained the summit of the citadel experienced the same cruel fate as the rest (for those whom the Albanian soldiers made prisoners met with no mercy from their chiefs or from Mohammad 'Alee), but it soon became impossible for any to retrace their steps even so far; the road was obstructed by the bleeding bodies of the slain Memlooks, and their richly caparisoned horses, and their grooms. Four hundred and seventy Memlooks entered the citadel; and of these, very few, if any, escaped. One of these is said to have been a Bey. According to some, he leaped his horse from the ramparts, and alighted uninjured, though the horse was killed by the fall; others say that he was prevented from joining his comrades, and discovered the treachery while waiting without the gate. He fled, and made his way to Syria. This massacre was the signal for an indiscriminate slaughter of the Memlooks throughout Egypt, orders to this effect being transmitted to every governor; and in Cairo itself, the houses of the Beys were given over to the soldiery, who slaughtered all their adherents, treated their women in the most shameless manner, and sacked their dwellings. During the two following days, the Pâshâ and his son Toosoon rode about the streets, and endeavoured to stop these atrocious proceedings; but order was not restored until 500 houses had been completely pillaged. In extenuation of this dark blot on Mohammad 'Alee's character, it has been urged that he had received the order for the destruction of the Memlooks from Constantinople, whither the heads of the Beys were sent. It may be answered to this plea, that on other occasions he scrupled not to defy the Porte.

The massacre of the Memlooks.

A remnant of the Memlooks fled to Nubia, and a tranquillity was restored to Egypt to which it had long been unaccustomed, and which has rarely been interrupted since. In the year following the massacre the unfortunate exiles were attacked by Ibrâheem Pâshâ, the eldest son of Mohammad 'Alee, in the fortified town of Ibreem, in Nubia. Here the want of provisions forced them to evacuate the place; a few who surrendered were beheaded, and the rest went further south and built the town of New Dongola,[2] where the venerable Ibrâheem Bey died in 1816, at the age of 80. As their numbers thinned, they endeavoured to maintain their little power by training some hundreds of blacks; but again, on the approach of Ismâ'eel, another son of the Pâshâ of Egypt, sent with an army to subdue Nubia and Sennâr, some returned to Egypt and settled in Cairo, while the rest, amounting to about 100 persons, fled in dispersed parties to the countries adjacent to Sennâr.

War with the Wahhâbees.

Mohammad 'Alee being undisputed master of Egypt, at the reiterated commands of the Porte, despatched, in 1811, an army of 8000 men, including 2000 horse, under the command of Toosoon Pâshâ, against the Wahhâbees. After a successful advance, this force met with a serious repulse at the pass of Safrâ and Judeiyideh, and retreated to Yembo'. In the following year Toosoon, having received reinforcements, again assumed the offensive, and captured El-Medeeneh, after a prolonged siege. He next took Jiddeh and Mekkeh, defeating the Wahhâbees beyond the latter place, and capturing their general. But some mishaps followed, and Mohammad 'Alee, who had determined to conduct the war in person, left Egypt for that purpose in the summer of 1813. In Arabia he encountered serious obstacles from the nature of the country and the harassing mode of warfare adopted by his adversaries. His arms

[1] The account of this expedition is taken from published official papers, Mengin, &c.

[2] Correctly Dunkulah, but pronounced by the natives Dungulah.

met with various fortune; but on the whole his forces proved superior to those of the enemy. He led a successful expedition in the Hijáz, and on the conclusion of a treaty with the Wahhábee chief, 'Abd-Allah, in 1815, he returned to Egypt on hearing of the escape of Napoleon from Elba.

He now confiscated the lands belonging to private individuals, merely allowing them a pension for life, and attempted to introduce the European system of military tactics. A formidable mutiny, however, broke out in the metropolis, the Páshá's life was endangered, and he sought refuge by night in the citadel, while the soldiery committed many acts of plunder. The revolt was reduced by presents to the chiefs of the insurgents, and Mohammad 'Alee very honourably ordered that the sufferers by the late disturbances should receive compensation from the treasury. The project of the "Nizám Gedeed," as the European system is called in Egypt, was, in consequence of this commotion, abandoned for a time.

Soon after Toosoon returned to Egypt, but Mohammad 'Alee, dissatisfied with the treaty which had been concluded with the Wahhábees, and with the non-fulfilment of certain of its clauses, determined to send another army to Arabia, and to include in it the soldiers who had recently proved unruly. This expedition, under Ibráheem Páshá, left in the autumn of 1816. After several unimportant advantages, Ibráheem sat down before the town of Er-Rass; but three months' exertions proving unavailing, he raised the siege, with the loss of nearly half his army. Notwithstanding, he advanced on the capital, Ed-Dir'eeyeh, by slow but sure steps. The last place before reaching that city offered a brave resistance, and Ibráheem, in revenge, caused all its inhabitants to be put to the sword, excepting a number of women and children, the former of whom were spared not from motives of pity. Ed-Dir'eeyeh fell after a five months' siege, in the course of which an explosion destroyed the whole of the besiegers' powder; and had the Wahhábees been aware of the extent of the disaster, few, we may believe, would have escaped to tell the tale. 'Abd-Allah, their chief, was taken, and with his treasurer and secretary was sent to Constantinople, where, in spite of Ibráheem's promise of safety, and of Mohammad 'Alee's intercession in their favour, they were paraded and put to death. At the close of the year 1819, Ibráheem returned to Cairo, having conquered all present opposition in Arabia, but without having broken the spirit of the Wahhábees.

The Páshá, since his return from Arabia, had turned his attention to the improvement of the manufactures of Egypt, and engaged very largely in commerce. The results of these attempts are stated in other places, but the important work of digging the new canal of Alexandria, called the Mahmoodeeyeh, must here be again mentioned. The old canal had long fallen into decay, and the necessity of a safe channel between Alexandria and the Nile was much felt. Such was the object of the canal then excavated, and it has on the whole well answered its purpose; but the sacrifice of life was enormous, and the labour of the unhappy Felláhs was forced. Towards the accomplishment of a favourite project, the formation of the Nizám Gedeed, a force was ordered to the southern frontier of Egypt, and the conquest of Sennâr was contemplated in order to get rid of the disaffected troops and to obtain a sufficient number of captives to form the nucleus of the new army. The forces destined for this service were led by Ismá'eel, then the youngest son of Mohammad 'Alee; they consisted of between four and five thousand men, Turks and Arabs, and were despatched in the summer of 1820. Nubia at once submitted, the Shágeeyeh Arabs immediately beyond the province of Dongola were worsted, and Sennâr was reduced without a battle. Mohammad Bey, the Defterdâr, with another force of about the same strength, was then sent by Mohammad 'Alee against Kurdufân with a like result, but not without a hard-fought engagement. In 1822, Ismá'eel was, with his retinue, put to death by an Arab chieftain by name Nimr; and the Defterdâr, a man infamous for his cruelty, assumed the command in those provinces, and exacted terrible retribution from the innocent inhabitants.

The Greek war. In the years 1821 and 1822 Mohammad 'Alee despatched both ships and men (the latter about 7000 or 8000 Albanians and Turks) to the Morea, Cyprus, and Candia, to aid the Porte in reducing the Greek insurrection; and he continued to take part in that struggle, his fleet being engaged at Navarino, until the English insisted on the evacuation of the Morea, in 1828, by Ibráheem Páshá. In the latter of the two years before mentioned (1822), an army of disciplined troops was at length organized: 8000 men (chiefly slaves, from Sennâr and Kurdufân) were trained by French officers at Aswân. Of the vast numbers seized in the countries above named, many died on the way: those who were not eligible were, with the women, sold in Cairo, and in the remainder were incorporated many Felláhs. Colonel Sève (now Suleymán Páshá), a Frenchman who afterwards became a Muslim, superintended their organization; great numbers of the Blacks died of hypochondria, but the Egyptians proved very good troops. Many thousands were pressed in consequence, and they now constitute the bulk of the army. In 1823 the new conscripts amounted to 24,000 men, composing six regiments of infantry, each regiment consisting of five battalions of 800 men, and the battalions of eight companies of 100 men. The organization, pay, &c., of the Egyptian army will be found under section iv.

In 1824, a native rebellion of a religious character broke out in Upper Egypt, headed by one Ahmad, an inhabitant of Es-Sálimeeyeh, a village situate a few miles above Thebes. He proclaimed himself a prophet, and was soon followed by between 20,000 and 30,000 insurgents, mostly peasants, but some deserters from the Nizám, for that force was yet in a half organized state, and in part declared for the impostor. The insurrection was crushed by Mohammad 'Alee, and about one-fourth of Ahmad's followers perished, but he himself escaped and was never after heard of. Few of these unfortunates possessed any other weapon than the long staff (Nebboot) of the Egyptian peasant; still they offered an obstinate resistance, and the combat resembled a massacre. In the same year war was once more made on the Wahhábees, who had collected in considerable numbers. The 2d regiment was sent on this service, and it behaved in a very creditable manner.

The war with the Porte. But the events of the war with the Porte are perhaps the most important of the life of Mohammad 'Alee. The campaign of 1831 had ostensibly for its object the castigation of 'Abd-Allah, Páshá of Acre: the invading force consisted of six regiments of infantry, four of cavalry, four field-pieces, and a greater number of siege-guns, the whole under the command of Ibráheem Páshá, while the fleet, conveying provisions, ammunition, &c., was to accompany the army by sea. The terrible cholera of 1831, however, stayed the expedition when it was on the eve of departing; 5000 of its number died, and it was not until early in October of the same year that it started. Little opposition was encountered on the way to Acre, whither Ibráheem had gone by sea, and that place was invested on the 29th of November. The artillery of the besieged was well served; an assault in the following February was repulsed, and the cold and rain of a Syrian winter severely tried the Egyptian troops. A second assault in like manner failed, and Ibráheem was called away to repel 'Osmán Páshá, governor of Aleppo. The latter, however, hastily decamped without giving him battle, and Ibráheem, deeming this advantage sufficient, retraced his steps towards Acre. He then pushed the siege with fresh vigour, and stormed the city on the 27th of May:

Egypt.

1400 men fell in the breach, and the garrison was found to be reduced to about 400 men. The fall of Acre was followed by negotiation. Mohammad 'Alee evinced a disposition for peace, but demanded the government of Syria, and the Porte, in consequence, denounced him as a traitor. On his part, Ibrâheem pushed his successes: Damascus was evacuated at his approach, and the battle of Hims, fought on the 8th of July 1832, decided the superiority of the Egyptian army, and the advantage of disciplined troops over an irregular force, although very disproportionate in numbers. The enemy composed the advanced guard of the Turkish army, 30,000 strong, and the Egyptians numbered only 16,000 men.

After this victory, Ibrâheem marched to Hamâh, and thence to Aleppo (which had just before closed its gates against the Turkish general-in-chief, Hoseyn Páshá, whose troops became rapidly disorganized), forced the defiles of Beylân, and pursued the fugitive Turks to Adaneh. About the same time an Egyptian squadron had chased the Sultán's fleet into Constantinople. Diplomacy was, at this point, again resorted to, but without any result; the Sultán depended on his fleet to protect the capital, and determined to risk another engagement with the victorious enemy. The charge of this venture was intrusted to Resheed Páshá, the Grand Vezeer. In the mean time, Ibrâheem Páshá had gained the pass of Taurus, and having beaten the Turks at Oulou-Kislák, he hesitated not to give battle to Resheed Páshá at the head of about 60,000 men, his own army being less than half that strength; the battle of Kónyeh, on the plains of Anatolia, proved utterly disastrous to the Porte: in the confusion of the fight, and the darkness of a thick day, the Grand Vezeer was made prisoner, his army routed, and Constantinople was within six marches of the victor, without an army to oppose his passage. The capital of the Ottoman Empire, in imminent danger by sea and land, was then intrusted to the keeping of its hereditary enemy, as the last resource of the Sultán Mahmood, and a Russian fleet and army were sent thither. Negotiations were, in consequence, opened, and on the 14th of May 1833, a treaty was concluded between Mohammad 'Alee and the Porte, by which the whole of Syria and the district of Adaneh were ceded to the former, on condition of his paying tribute. With this terminated the war, but not the animosity of the Sultán. Ibrâheem, by excessive firmness and rigour, speedily restored security and tranquillity to the greater part of Syria; but some years later, the attempt of Mahmood to get the better of his vassal, and the consequent disaster experienced by his arms at Nezeeb, entailed fresh complications, and the interference of Great Britain ended in the restoration of Syria to the Porte in 1841. The political motives which actuated the Great Powers at this time and in 1831 need not be here discussed; and the operations on the coast of Syria, the bombardment of Acre, and the blockade of Alexandria, are familiar to most newspaper readers. It is undoubtedly true that Mohammad 'Alee placed all his reliance on the co-operation of France, and to its desertion of his cause, and his confidence in its assistance, either morally or physically, must be ascribed the unfortunate issue of the war. That the Syrians, in general, preferred the rule of Mohammad 'Alee to the tyranny of Páshás appointed from Constantinople may be safely averred; but we cannot close this account of his possession of that province without animadverting on the horrible cruelties perpetrated by Ibrâheem Páshá, or warning our readers not to give credence to the unmeasured praise bestowed by many on the Egyptian troops there engaged. Conceding that they were superior soldiers to the Turks, it must be borne in mind that they were veterans, disciplined and led by French officers and an able general: their opponents were destitute of any European discipline, badly officered, and discouraged by the disasters in Greece. It has, moreover, been stated on good authority, that Ibrâheem owed much of his success to the placing of artillery in the rear of his troops, with orders to fire on them should they show symptoms of wavering.

Treaty of 1833.

After the peace of 1841, Mohammad 'Alee gave up all grand political projects, and solely occupied himself in improvements, real or imaginary, in Egypt. He continued to prosecute his commercial speculations and manufacturing, educational, and other schemes. The barrage of the Nile, still uncompleted, was commenced by his direction, and in 1847, he visited Constantinople, where he received the rank of Vezeer. In the year 1848, however, symptoms of imbecility appeared, and after a short space Ibrâheem was declared his successor. But his rule was very short. In about two months he died; and, according to the terms of the treaty, Abbâs, a son of Toosoon, and the eldest representative of the family, succeeded to the pashalic. This miserable voluptuary, and withal bigoted, though ignorant, Muslim, utterly neglected the affairs of government, and solely consulted his own gratification. He died suddenly, and, as some assert, mysteriously, in July of last year (1854); and the present Viceroy, Sa'eed Páshá, the fourth son of Mohammad 'Alee, by his energy of character and superior intelligence, gives us some hope that Egypt may improve under his rule. He has, it is said, abolished certain government monopolies, is busily occupied in carrying out the works of the barrage, and takes great pains with the disciplining of his army. He is, besides, known to be favourable to the English. But he is new to his office, and it would be idle to speculate on the future career of an Egyptian Turk.

Ibrâheem Páshá.

Abbâs Páshá.

Sa'eed Páshá.

Mohammad 'Alee survived Ibrâheem, and died on the 3d of August 1849. Many and conflicting have been the opinions entertained of this remarkable man; for such at least all acknowledge him to have been. His massacre of the Memlooks has been the great point of attack by his enemies; but that, as well as many other of his acts, must be ascribed to his boundless ambition, not to innate cruelty; for he has proved himself to be averse to unnecessary bloodshed. That he really esteemed European civilization may be doubted; but his intelligent mind could not fail to perceive that therein lay his great strength, and of this he availed himself with consummate ability. To his firm government Egypt is indebted for the profound tranquillity which it has long been its good fortune to enjoy: a traveller of any nation or faith may traverse it in its length and breadth with greater safety than almost any other country out of Western Europe; and the display of fanaticism has been rigorously punished. This has undoubtedly increased the hatred of the Muslims for the professors of other religions; but we may hope that it will eventually produce a better state of feeling. While, however, Egypt has benefited by the establishment of order, the people have suffered most severe exactions. The confiscation of private lands has been before mentioned: to that arbitrary act must be added the seizure of the lands of the mosques, the imposition of heavy taxation, and a system of merciless impressment. In fact, the condition of the Egyptian Fellâh has rarely been as wretched as it is at the present day. He also misunderstood the real resources of Egypt, which are certainly agricultural; by the much-lauded introduction of cotton, he dealt a severe blow to native produce; and he did more to injure the country by endeavouring to encourage manufacturing industry, and by establishing enormous government monopolies, a measure which crushed the spirit of the agriculturists. His military and governing abilities were assuredly very great, and his career is almost unequalled in Turkish history. Had it not been for the intervention of Great Britain, his Syrian successes over the Porte would probably have led to very beneficial results, by rescuing Egypt from the wretched condition of a Turkish province.

Egypt.

But the firmân of 1841 entailed the loss of all his military power, the army was reduced to 18,000 men, and the navy condemned to rot in the harbour of Alexandria, while Mohammad 'Alee, failing to gain the great object of his ambition, the establishment of an independent dynasty, and being compelled to look on his then living family as his only heirs, thenceforth confined himself to measures of lesser importance, and did not prosecute even these with his former energy.

The entire constitution of the government of Egypt is the work of Mohammad 'Alee. With few exceptions he destroyed all former usages, and introduced a system partly derived from European models. The army and navy are of his creation, so are the taxation, the regulation of import and export duties, &c., quarantine laws, the manufactories, colleges, and the ministry. Some of these institutions are useful; others, both vexatious and ill calculated for the country. The colleges of languages and medicine, and the printing-press at Boolâk, are among the former, and are exceedingly praiseworthy efforts in a right direction; and in the same category must be placed many minor improvements, in which Mohammad 'Alee showed himself to be far in advance of his countrymen; while, weighing his chequered life, and numerous disadvantages of position and nation, his moral character, enlightened mind, and distinguished ability, must place him high among the great men of modern times.

SECTION III.

TOPOGRAPHY AND MONUMENTS.[1]

Lower Egypt. General aspect.

The northern coast of Egypt is low and barren, presenting no features of interest, and affording no indication of the character of the country which it bounds. It is a barrier, generally of sand-hills, but sometimes of rock, for the most part altogether destitute of vegetation, except where grow a few wild and stunted date-palms. Immediately behind are desolate marshy tracts or extensive salts lakes, and then the fertile country. The last is a wide plain, intersected by the two branches of the Nile, and by many canals, whereof some were anciently branches of the river, and having a soil of great richness, though in this particular it is excelled by the valley above. The only inequalities of the surface are the mounds of ancient towns, and those, often if not always ancient, on which stand the modern towns and villages. The palm-trees are less numerous, and not so beautiful as in the more southern part of the country, though other trees are more common. The houses and huts of the towns and villages are of burnt brick near the Mediterranean; but as the climate becomes drier, and the occurrence of rain far less frequent, the use of crude brick obtains, until near the point of the Delta it is very general. The mosques even of the towns are rarely remarkable for architectural beauty in the tract to the north of Cairo. The palaces or villas of the Turkish grandees, which are not uncommon, have, however, a light and picturesque appearance, though their style is not good. The deserts which inclose the plain on either side are rocky tracts of very slight elevation, having their surface overspread with sand, pebbles, and débris.

Alexandria.

Of the towns on the northern coast, the most western, Alexandria, called by the natives El-Iskendereeyeh, is the largest and the most important. It was founded in the year B.C. 332 by Alexander the Great, who gave it the form of a Macedonian mantle (chlamys). The ancient city occupied the space between the sea and the lake Mareotis, being about four miles in its greatest length, and a little less than a mile in its greatest breadth.[2] The island of Pharos was likewise inhabited, and was joined to the continent by the mole called the Heptastadium, a work of Ptolemy Philadelphus, or of his father the first Ptolemy, or of Alexander himself. The Heptastadium and the island divided the bay into two harbours. These were spacious, and although the western, anciently called Eunostus Portus, but now the Old Port, is difficult to enter, and the eastern, Magnus Portus, or the New Port, is not so deep and is less secure, they are by far the best anchorages on the coast of Egypt, and there is nothing else deserving the name of a harbour, nor does there ever seem to have been. Alexandria, which partly occupied the site of the ancient Rhacôtis, a place of little importance, speedily increased in consequence, and became the emporium of the trade between Europe, Arabia, and India, owing this prosperity to its harbours. After the death of Alexander the city became the capital of Ptolemy, the son of Lagus, the founder of a dynasty which generally held more extensive dominions than the kingdom of Egypt, and at one time ruled an empire not inferior to that of the most successful of the Pharaohs. By the Ptolemies, Alexandria was adorned with palaces and temples of great magnificence, for which they did not scruple to despoil more ancient edifices of some of their chiefest ornaments. While its commercial importance increased, it became a celebrated seat of learning, through the wise interest with which the Greek kings regarded science and letters, and Ptolemy Soter commenced the famous Library. Under the Ptolemies, however, the inhabitants, who were chiefly Greeks, became very troublesome to their rulers, like most commercial populations, and their turbulence was ill restrained by the weakness of the later sovereigns of that line. From the time of the Roman Conquest, B.C. 30, until it was taken by the Arabs, A.D. 640, Alexandria sensibly declined, partly in consequence of its being a provincial capital, instead of a royal residence, but chiefly because of the unruly disposition of its inhabitants, and their violent religious and political disputes, which at last resulted in the seat of government being transferred to the fortress of Egyptian Babylon, near the modern Cairo, which became in some sort the capital. During this time it was distinguished for the learning of its ecclesiastics, and the strong part which they took in the theological differences of the early Church. Under the Muslims, Alexandria never regained the position of metropolis of Egypt, and its importance, with some fluctuations, waned until the discovery and consequent adoption of the route to India by the Cape of Good Hope almost withdrew the main cause of its prosperity. Recently, however, the resumption of the overland route has greatly benefited this city, and although it was not made the capital, it became the favourite residence of Mohammad 'Alee, which in like manner contributed to its welfare.

The older part of the town of Alexandria stands upon the Heptastadium, which is much wider than of old, but the recent part, where are the houses of the European merchants, occupies the site of a portion of the ancient city which was nearest to the mole. The most striking edifice is the castle on the island of Pharos, containing a lighthouse, which has succeeded to the more famous Pharos of antiquity. Here also is the Páshâ's palace, as well as a lesser Pharos. The houses of the town are built of stone, or have their lowest story cased with that material, and the portion above of brick plastered and whitewashed. The residences of the European merchants and consuls are spacious and well-built, somewhat in the modern Italian style, but have no claims to architectural beauty. The mosques are not

[1] The following account of the topography and monuments of Egypt is the result of personal observations made during a long residence in that country. It is not therefore deemed necessary to append references, except in cases of particular importance, or where information has been derived from published works.

[2] Comp. Strabo, xvii. 1; and Diod. xvii. 52.

Egypt.

remarkable, but the English church will, if ever completed, be a great ornament to the town. The population is estimated at about 80,000 (including the garrison and sailors of the fleet), by Sir Gardner Wilkinson (1843).[1] One of the favourite projects of Mohammad 'Alee was the fortification of Alexandria, which has been thus rendered so strong that if well garrisoned it could not be invested by a force of less than about 40,000 men.

The remains of ancient buildings are very scanty and of little interest, compared to those which are seen on the sites of other Egyptian towns. Two objects are conspicuous, one of the obelisks commonly but inaccurately called "Cleopatra's Needles," and the great column which is as incorrectly named "Pompey's Pillar." The former is a fine obelisk of red granite nearly seventy feet in height, bearing hieroglyphic inscriptions with the names of Thothmes III., Rameses II., and a later king. Beside it is a fallen obelisk of the same dimensions, its fellow. They were brought here from some ancient temple during the Greek or Roman rule. "Pompey's Pillar" is in like manner of red granite, and its shaft is about seventy feet high, the whole column being nearly a hundred in height. An inscription in Greek upon its pedestal states that it was dedicated to the Emperor Diocletian, but it is not certain that it was set up to him, nor that it did not form one of a series of such columns, which, however, is unlikely, from its great size.[2] The other remains are not worthy a special description in this article, as space would be thus occupied that must be devoted to more remarkable monuments.

Rosetta.

Proceeding to the east of Alexandria, the first place of importance is Er-Rasheed, called by the Europeans Rosetta, a considerable town on the west bank of the branch of the Nile, named the Rosetta Branch, and anciently the Bolbitine. Before the cutting of the Mahmoodeeyeh Canal by Mohammad 'Alee, to connect Alexandria with this branch of the river, Rosetta was a place of greater importance than now, as the overland trade from India chiefly passed through it, in consequence of the decay of the old canal of Alexandria. It is a well-built town, having some gardens, like most of those of Egypt rather picturesque than beautiful, and it is in many respects more agreeable than Alexandria. Its population is stated by Clot-Bey to be scarcely 15,000.[3] A little to the north of the town is the boghâz, a bar of sand stretching across the mouth of the river, and rendering it often impassable; and between it and Rosetta is an old fort called Fort St Julien by the French who repaired it during their occupation of Egypt, when one of their officers discovered the trilingual tablet thence called the Rosetta Stone, which afforded the clue by which the Egyptian hieroglyphics were interpreted.

Saïs.

In ascending the Rosetta Branch, the first place of interest is the site of Saïs, on the eastern bank, marked by lofty mounds, and the remains of massive walls of crude brick, but nothing of greater interest. Perhaps, however, some ruins of the great temple may be buried here. Its position is marked by the walls of crude brick above mentioned, which were those of a great enclosure in which it and doubtless other sacred edifices stood. Saïs was one of the most ancient cities of Egypt, and from it Cecrops is said to have led a colony to Athens. The goddess Neit or Neith was the divinity of the place, and a festival of great solemnity was annually held here in her honour, to which pilgrims resorted from other parts of Egypt. Saïs was remarkable for the learning of its priests, and for a time held a high political position when Egypt was ruled by the kings of the powerful Twenty-sixth Dynasty, whose native place it was, though it does not seem to have been capital of the country. A modern village here is called "Sá-el-Hagar," or "Saïs of the Stone," a name which probably alludes to the famous monolith described by Herodotus.[4]

Towns in the Delta.

In the interior of the modern Delta no remains of importance have been discovered, though there are many ancient sites marked by mounds. The chief towns are El-Mahalleh el-Kebeereh, not far from the Damietta Branch, about forty miles from the sea; Tantà, nearly in the middle of the Delta; and Manoof, farther south. Of these Tantà is best known as the birth-place of the Muslim saint called the seyyid Ahmad El-Bedawee, in whose honour three festivals are annually kept, the greatest of which attracts more pilgrims than any other in Egypt, and is second alone to the pilgrimage to Mekkeh in this particular. Like many celebrations of the kind, the festivals of Tantà are rather distinguished by riot than piety, and recall the revelries of Bubastis and Canopus.

Damietta.

Several sites of interest are found on the course of the Damietta Branch, the old Phatnitic or Phatmetic. First of these is the town whence it takes its name, Dimyât, called by the Europeans Damietta, which stands not far from the mouth of this branch, and on its eastern side. In the time of the Crusades it was a strong place, and regarded as the key of Egypt. It was taken and retaken by the contending forces, and formed the basis of the operations of St Louis in the unfortunate Eighth Crusade. Shortly afterwards the Memlook Sultân Edh-Dhâhir Beybars, in A.D. 1251, razed it and rebuilt it on the present site somewhat further from the sea. It is a flourishing town, and has a population of about 28,000 inhabitants, according to Sir Gardner Wilkinson.[5] The next place of importance is the town of El-Mansoorah, founded by El-Melik El-Kâmil, the nephew of Salâh-ed-Deen, during the Sixth Crusade, to commemorate, as its name imports, his success over the invading army of Jean de Brienne.

El-Mansoorah.

A little to the south of El-Mansoorah, on the opposite bank, at a short distance from the river, are the remains of a very remarkable temple of the goddess Isis, and the mounds of the town of Iseum.

Iseum.

Although the temple is entirely thrown down, as though by a natural convulsion, but no doubt by human violence, its plan may be partly traced and its date ascertained, since the materials have not been removed. It was, unlike most Egyptian temples, built altogether of granite,[6] and about 600 feet in length and 200 in breadth. The materials must have been transported from Syene, a distance by the river, on which they were doubtless floated, of more than 600 miles. Bearing in mind this circumstance, and the difficulty of both working and sculpturing so hard a material, this temple must be considered to be one of the most costly in the country. The earliest name which has been found here is that usually assigned to Amyrtæus of the Twenty-eighth Dynasty, but the most common one is that of Ptolemy Philadelphus. It was in this part of Egypt that Amyrtæus found a refuge during his long contest with the Persians, and it seems not improbable that when he had at last mounted the throne, and made Egypt once more an independent kingdom, he testified his pious gratitude by commencing this magnificent edifice.

Semennood (Sebennytus).

A little to the south of this site is the small town of Semennood, anciently Sebennytus, the city of Hercules, in like manner on the western bank of the river; and a short distance farther, on the same side, is the village of Aboo-Seer, the ancient Busiris, named after Osiris, who, with Isis, was here worshipped.

Aboo-Seer (Busiris).

Herodotus mentions, among the great festivals, that of Isis held at the latter place, but this was more probably kept at Iseum, which was near by.

Tel-Atreeb (Athribis).

For a considerable distance there is nothing of interest until we reach Tel-Atreeb, where the

[6] The temple of Bubastis at the city of the same name was likewise entirely of red granite. *Mod. Egypt and Thebes*, vol. i., p. 428.

Egypt.

site of the town of Athribis is marked by high mounds, with remains of ancient houses and some blocks of stone.

Pelusium. To the eastward of the Damietta Branch, in the broad cultivated tract or the desert beyond, are some places worthy of note. The most eastern of these is the site of Pelusium, which was, in the times of the Pharaohs of the Twenty-sixth Dynasty, and probably earlier, the key of Egypt towards Palestine.[1] No important remains have been discovered here. Between this site and the Damietta Branch

Tanis. are the mounds of Tanis, or Zoan, where are considerable remains of the great temple, the most remarkable of which are several fallen obelisks, some of which are broken. From their inscriptions, and those of other blocks, it has been ascertained that the temple was as ancient as the time of the Twelfth Dynasty, and was much beautified by Rameses II. and other kings of that time and the subsequent period. Tanis was on the eastern bank of the Tanitic branch of the Nile, now called the canal of the El-Mo'izz. On the same side of the same branch, but considerably to the south, was

Bubastis. the city of Bubastis, the site of which is indicated by very lofty mounds, in which may be traced the remains of its great temple. Here was held the festival of the goddess Bubastis, which attracted great crowds of pilgrims, and is ranked by Herodotus first of the festivals of Egypt.

Bilbeys. Not far south, and on the borders of the desert, is Bilbeys, which was a place of some importance as a frontier-town in the time of the Eiyoobee princes. Still farther south are

Onion. the mounds of Onion, the Jewish city founded by the high priest Onias, where was a temple closed by Vespasian not long after the overthrow of Jerusalem. The site is called Tell-el-Yahoodeeyeh, or "The Mound of the Jewess."

The Barrage. At the point of the Delta is the unfinished Barrage, which was intended, by crossing both branches of the river, to regulate the inundation above and below this place. The river here becomes broader, as it is generally for a great distance higher, than in its divided state. A little south of the point of the Delta, on the eastern bank of the river, near the village of El-Matareeyeh, is the site of

Heliopolis. the ancient Heliopolis, the City of the Sun, marked by a solitary obelisk, and crude brick ridges formed by the ruins of a massive wall. The obelisk bears the name of Sesertesen I., the head of the Twelfth Dynasty, in the simple inscription, which runs down each of its sides. It is of red granite, and nearly 70 feet in height. The city was famous rather for the learning of its college than for its size, and the temple of Ra was held in high veneration. Many famous Greek philosophers studied here, and much that has been supposed to have been discovered by them was probably derived from their Egyptian instructors. At a short distance south of Heliopolis is the modern metropolis of Egypt, Cairo, not far inland.

Boolák. Boolák, the port of Cairo, is a considerable and flourishing town, having two remarkable mosques, and a very large palace, built by Isma'eel Páshá, a son of Mohammad 'Alee, who fell a victim to a conspiracy caused by his own tyranny, while commanding an expedition in Upper Nubia. It was founded A.H. 713, in the reign of the Sultán Mohammad Ibn Kalá-oon. Two principal roads lead hence to the metropolis, distant about a mile.

Cairo. Cairo is the fourth Muslim capital of Egypt: the site of one of those that have preceded it is, for the most part, included within its walls, while the other two were a little to the south. 'Amr, the Muslim conqueror of the country, founded El-Fustát, the oldest of these, close to the fortress of Egyptian Babylon, the seat of government at that time. Its name signifies "The Tent," as it was built where 'Amr had pitched his tent. The new town speedily became a place of importance, and was the residence of the Náïbs, or lieutenants, appointed by the orthodox and Umawee Khaleefehs. It received the name of Masr, properly Misr, which was applied by the Arabs to every important capital of the country, Thebes and Alexandria excepted. It declined after the foundation of El-Káhireh, but never became altogether deserted, for a small town, called Masr El-'Ateekah, or "Old Masr," occupies, in the present day, part of what was its area in its time of prosperity. Shortly after the overthrow of the Umawee Dynasty, and the establishment of the Abbásee, the city of El-'Askar was founded (A.H. 133) by Suleymán, the general who subjugated the country, and became the capital and residence of the successive lieutenants of the Abbásee Khaleefehs. El-'Askar was a small town adjacent to El-Fustát, of which it was a kind of suburb. Its site is now entirely desolate. The third capital, El-Katáë', or El-Katáyë', was founded about A.H. 260, by Ahmad Ibn-Tooloon, a lieutenant who rendered himself independent of the Abbásee Khaleefeh, and made this his capital. It continued the royal residence of his successors; but not long after the fall of the Dynasty, and a subsequent one, the seat of government was transferred by the Fátimees to a new city, El-Káhireh. El-Katáë', which had been sacked on the overthrow of the Tooloonees, rapidly decayed. A part of the present Cairo occupies its site, and contains its great mosque, that of Ahmad Ibn-Tooloon.

Góhar el-Káïd, the general who subjugated Egypt to the power of his master, the Fátimee Khaleefeh El-Mo'izz, founded a new capital A.H. 358, which was named El-Káhireh, that is, "the Victorious," which has been corrupted into Cairo. This town occupied about a fourth part of the present metropolis, being the north-eastern portion. By degrees it became greater than El-Fustát, and took from it the name of Misr or Masr, which is applied to it by the modern Egyptians. It continually increased, so as to include the site of El-Katáë' to the south, and of the old town of El-Maks to the west. The famous Saláh-ed-Deen, or Saladin, built a citadel on the lowest point of the mountain to the east, which immediately overlooked El-Katáë', and he partly walled round the towns and large gardens within the space now called Cairo. Under the prosperous rule of the Memlook Sultáns this great tract was filled with habitations; a large suburb to the north, the Hoseyneeyeh, was added; and the town of Boolák founded. Since the Turkish conquest (A.D. 1517) the metropolis has constantly decayed, but its limits are the same.

Cairo is of an irregular oblong form. Its greatest length is about three miles, and its average breadth about a mile and a half, and its dimensions do not fall very much short of these in any part.[2] This surface is not, however, entirely occupied by houses, for it contains the citadel, various extensive gardens and open spaces, as well as lakes. The streets are extremely narrow, and the markets generally crowded, so that the stranger usually acquires a delusive idea of the density of the population. Mr Lane states the population to have been 240,000 before the great plague of 1835, and adds that the deficiency, equal to not less than one-third of the inhabitants, caused by that terrible visitation, would be speedily supplied from the villages.[3] Sir Gardner Wilkinson, in his *Modern Egypt and Thebes*,[4] published in 1843, gives the population at about 200,000; and Mrs Poole, writing in 1842, estimates it at about 240,000;[5] but Clot-Bey,[6] whose work appeared in 1840, states the much higher amount of about 300,000 souls. The census of 1847–8, already noticed,[7] states the more moderate sum of 253,541 inhabitants, and in this instance it is not likely to have been far wrong. We may fairly suppose that during the time of

[1] See above, section ii.

[2] M. Jacotin, in the *Description de l'Egypte*, t. xviii. 2, p. 111, estimates the superficies of Cairo at 793 hectares, or about 3 square miles.

Egypt.

comparative prosperity that followed the great plague of 1835 the population gradually increased to about 250,000, and that the cholera in 1848 and the recent conscriptions occasioned by the war between Turkey and Russia have somewhat diminished its amount, which may at the present time be stated at above 200,000, and probably little below 250,000. Of the population of 240,000 in 1834, according to Mr Lane, about 190,000 were Muslim Egyptians; about 10,000 Copts; 3000 or 4000 Jews; and the rest, strangers from various countries. The adult male population was about one-third of the whole, or 80,000 persons, of whom 30,000 were merchants, petty shopkeepers, and artisans; 20,000 domestic servants; 15,000 common labourers, porters, &c.; the remainder chiefly consisting of military and civil servants of the government.[1]

Cairo is still undoubtedly the most remarkable and characteristic of Arab cities. The beauty of its religious and domestic architecture, before the recent Turkish innovations, is unexcelled elsewhere. The edifices raised by the Moorish kings of Spain, and the Muslim rulers of India, may have been more splendid in their materials, and more elaborate in their details; the houses of the great men of Damascus may be more costly than were those of the Memlook Beys; but for purity of taste and elegance of design they are far excelled by many of the mosques and houses of Cairo. These mosques have suffered much in the beauty of their appearance from the effects of time and neglect; but their colour has been often thus softened, and their outlines rendered the more picturesque. What is most to be admired in their style of architecture is its extraordinary freedom from restraint, evidenced in the wonderful variety of its forms, and their being frequently irregular with respect to one another without offending the eye, as well as the skill in design which has made the most intricate details to harmonize with grand outlines. Its beauty seems to resemble that of nature, ever changing, yet ever harmonious, irregular without disproportion, because it appeals to a higher feeling than that which judges by the cold rules of geometry. Yet it never attains to sublimity, unlike the older architecture of the country; for the religion which originated it[2] endeavoured by it to shadow forth the joys of a future paradise in which the senses were to be gratified rather than the soul. The ancient Egyptian raised his pyramid on a rock in the trackless waste, or excavated his sepulchre in one of its most secluded valleys; his time-defying temples stood in the desert, or raised their stern masses above the fields; the Muslim placed his mosque in cities, amidst the homes of men, and where its elegant minaret should be half hidden by the palms, and throw its shadow of red and white across a tranquil lake. Both have now passed away, the ancient art and the modern, and nothing has taken their place that can lessen regret or awaken hope. See the article Cairo.

Environs of Cairo.

To the east of Cairo is a bold spur of the mountains known as El-Gebel El-Mukattam. Beneath it, and to the north of the citadel, is the cemetery of Kāït Bey, remarkable for the splendid tombs of the Memlook Sultāns. The most beautiful of these is that of Kāït Bey from which it takes its name, but those of the Sultān Barkook and of El-Ghooree must not be passed by unmentioned. At a little distance to the north-east is the Gebel el-Ahmar or "the Red Mountain," and southward of this on the rocky tract is petrified wood in large quantities strewn on the surface. The space between Cairo and the Nile, varying from a mile to a mile and a half in breadth, is occupied by plantations which were made by Ibrāheem Páshá during his father's rule. Formerly this side of the city was, as the other three are still to a great extent, bounded by lofty mounds of rubbish; these he caused to be removed, and by doing so conferred a great benefit upon the inhabitants, as well as by planting with trees the intervening space. By irrigating this tract very freely by a steam-engine he considerably lessened the good he had effected, rendering the western part of the city somewhat damp. To the south of Cairo are a great cemetery containing the tomb of the Imâm Esh-Shâfe'ee, and an aqueduct, built by the Sultān El-Ghooree, which conducts water from the Nile to the Citadel; and further, the Roman fortress of Egyptian Babylon, now called Kasr-esh-Shema, and chiefly occupied by a Coptic convent, as well as the small town of Masr El-'Ateekah, which is all that remains of the famous metropolis El-Fustāt. It contains no remarkable edifices; in its immediate neighbourhood however is the oldest mosque in Egypt, that of 'Amr, the Muslim conqueror of the country, but it has been so frequently repaired and almost rebuilt, that it is impossible to form any idea of its original appearance. Opposite to Masr El-'Ateekah, from which it is separated by a very narrow branch of the Nile, is the island of Er-Rόdah, containing the famous Mikyâs or Nilometer, and Ibrâheem Páshá's garden, which was beautifully laid out after the European manner by the late Mr Traill, a Scottish horticulturist.[3]

El-Geezeh.

The chief place on the western bank of the river near Cairo is the small town of El-Geezeh, opposite Masr El-'Ateekah. El-Geezeh is best known as having given its name to the three most famous pyramids of Egypt, which are, with the small ones in their neighbourhood, called by both natives and the Franks the Pyramids of El-Geezeh. These marvellous structures stand on the slightly elevated border of the low Libyan range, not more than a quarter of a mile beyond the limit of the cultivated land. Before describing them it is necessary to form some idea of the great necropolis to which they belong.

Necropolis of Memphis.

The city of Memphis stood on the western bank of the Nile about ten miles above Cairo. The kings and people who dwelt there chose the nearest part of the desert as their burial-place, and built tombs on its rocky edge, or excavated them in its sides. The kings raised pyramids around which their subjects were buried in smaller sepulchres. The pyramids were grouped together, and often there is a considerable distance from one group to another. It must be borne in mind, however, that many pyramids have been nearly or wholly destroyed; yet as the largest undoubtedly remain, the general features of the necropolis cannot be much changed. From the citadel of Cairo we obtain a good view of the several groups. First, opposite to us, but a little to the south, are the three great pyramids of El-Geezeh, two of which exceed all the others in magnitude; at some distance farther south we see those of Aboo-Seer, likewise three in number, of much smaller dimensions; and not so far beyond them the great pyramid of Sakkārah, called from its form that of Steps, with smaller pyramids in its neighbourhood. Farthest of all, after a wider interval, are the two large pyramids of Dahshoor, which approach in size the great structures of El-Geezeh. There are more to

---

[1] *Modern Egyptians, loc. cit.*

[2] Arab or Moorish architecture must be held to have originated with Muslim nations. Many things it certainly owed to Byzantine; but as we have no example which does not present the most remarkable essential differences, we cannot say it was the offspring of that style any more than we can assert that Greek architecture was derived from Egyptian.

[3] This gentleman, during the many years for which he was occupied in forming the garden of Er-Rόdah, introduced various foreign trees and plants, and gained much information respecting the botany of the country. By his premature death a true friend of science has been carried away, and one who possessed beyond any of his contemporaries the combined knowledge and abilities needed by a describer of the Egyptian Flora, who should supply the deficiencies of Forskäl and Delile. That task he did not live to execute, to the lasting detriment of science and the regret of his many friends.

the south as far as the Feiyoom, the last being that of El-Lâhoon, but none to the south of the pyramids of Dahshoor can be included within the Memphite necropolis. That great tract, which was also the burial-place of Heliopolis, extended, if we measure from the ruined pyramid of Aboo-Ruweysh, somewhat to the north of those of El-Geezeh, to the southernmost pyramid of Dahshoor, throughout a space of nearly twenty miles, in almost every part of which some sepulchres have been discovered, while it cannot be doubted that many more await a fortunate explorer.

Pyramids of El-Geezeh.

The road to the pyramids of El-Geezeh from the town whence they derive their modern appellation, is through cultivated fields diversified by villages in palm-groves. As we approach them, these structures do not give us that idea of size that we had expected from our first distant view; and until we stand at their feet we do not appreciate their vastness. But as we endeavour to scan the height of the Great Pyramid, when about to commence its ascent, we fully realize a result that human labour has not achieved elsewhere. The very dimensions—a height of half a thousand feet, four sides each measuring the seventh of a mile—are in themselves gigantic; but when we know that this huge space is almost wholly solid, containing a few chambers so small as not to be worthy of consideration in calculating its contents, we discover that no monuments of man's raising elsewhere afford any scale by which to estimate its greatness.

Great Pyramid.

The present perpendicular height of the Great Pyramid is, according to the late General Vyse's excellent work, 450 ft. 9 in.; and its present base 746 ft. 0 in. It is about 30 feet lower than it was originally, in consequence of much of the outer masonry having been torn off, as well as the casing-stones; and its base is likewise smaller. Gen. Vyse gives the former height at 480 ft. 9 in., and the former base at 764 ft. 0 in. Like all the other pyramids, it faces the cardinal points. At the completion of the pyramid the faces were smooth and polished, but now they present a series of great steps formed by the courses of stone, and are in some places (particularly in the middle of each face, and at the angles, and about the entrance) much broken. The ascent is easy though fatiguing, and the traveller is amply rewarded by the view which he obtains from the platform, about 32 feet square, at the summit. The prospect of the fertile plain and valley on the one side, and of the undulating barren surface of the Great Desert on the other, as well as of the pyramids and tombs beneath, is alike remarkable from its character and the associations which it calls up. The examination of the interior is no less interesting. All other tombs but the Memphite pyramids and those which were simply pits were not closed, the upper chambers being intended for the performance of funeral rites when the family of the deceased visited his sepulchre. These pyramids, however, were most carefully closed. The chambers, which contained the bodies of the king, and of those (doubtless of his family) who were sometimes buried in the same structure, were without sculptures, and scarcely ornamented in any way, being sometimes wholly plain. The passages leading to them were only large enough to admit a sarcophagus, and after the king's burial were closed by the lowering of heavy stone portcullises, and the blocking up of the entrance. The desired object was security, and we must not, therefore, expect beauty or grandeur in chambers constructed for this purpose, although we cannot fail to admire their massive and gloomy aspect.

The entrance to the Great Pyramid is not far from the middle of the northern face, 49 ft. 0 in. in perpendicular height from the base. The fallen stones and rubbish have, however, raised a mound which reaches nearly to the entrance, the masonry about which having been torn down, we gain some idea of the construction of the pyramid. In this manner the passage has lost somewhat of its length. The passage itself is 3 ft. 11 in. high, and 3 ft. 5½ in. wide, and is lined with fine limestone. It descends at an angle of 26° 41′.[1] At a distance of 63 ft. 2 in. from the beginning of the roof of the present entrance, a second passage commences from this, taking an ascending direction. The entrance of this new passage is obstructed by great blocks of granite which entirely fill it, and have been passed by means of an excavation around them. We thus enter the ascending passage, which is of the same breadth and height as the former, and inclines at an angle of 26° 18′. The stones which line its roof and sides are very rough, and it has evidently been left unfinished. After ascending this passage for a distance of 109 ft. 7 in., we reach the Grand Passage, which, from its greater dimensions, presents a comparatively imposing appearance. It ascends at the same angle as the last, while a horizontal passage runs beneath it to a chamber to be subsequently mentioned. Just within the Grand Passage is the mouth of the Well, an irregular pit, partly excavated in the rock, leading to the lower portion of the first passage. Its object was probably to afford an exit to the workmen who had been engaged in closing the ascending passage. The Grand Passage is 7 ft. 2 in. in width at its base, 28 ft. high, and 156 ft. long. The blocks which compose its sides gradually approach, every course above the second projecting a little, and on each side is a stone bench. At the end of this passage a horizontal one commences, of much smaller but unequal dimensions, and 22 ft. 1 in. in length, leading to the Grand Chamber, commonly called the King's Chamber, which it enters at the eastern end of its north side. This, which is the principal sepulchral chamber (unless, indeed, there be an undiscovered one of greater importance), is lined with red granite, and measures in length 34 ft. 3 in., in width 17 ft. 1 in., and in height 19 ft. 1 in. It is altogether plain, and contains only a sarcophagus of red granite, which is equally unadorned. Above this chamber are five small ones, which may be called entresols, evidently designed to lighten the pressure of the superincumbent masonry, particularly as the uppermost of them has a pointed roof. Four of these were discovered by the late Gen. Howard Vyse, who found in them quarry-marks, bearing the names of Shufu and Num-shufu, the former of whom had been previously identified with the builder of this pyramid mentioned by Herodotus, Diodorus, and Manetho. These chambers are reached with difficulty, and chiefly by forced passages. The horizontal passage beneath the Grand Passage must now be described. This is but 3 ft. 10 in. high, and 3 ft. 5½ in. wide for the first 92 feet of its length, and then we descend a step and find the passage to be 5 ft. 8 in. high for 17 ft. 11 in. farther, until it enters the "Queen's Chamber," as it is usually called, at the eastern corner of its north side. This chamber is 18 ft. 9 in. long, and 17 ft. broad, and its extreme height is 20 ft. 3 in. It has a pointed roof, of great blocks of stone, inclined upwards and meeting in the middle. Within it is the entrance of a forced passage. The remainder of the first passage, beyond where the first ascending passage leads to the most interesting parts of the structure, remains to be noticed. It continues below the forced entrance to the ascending passage for a distance of 239 ft. 10 in., being cut through the rock on which the pyramid is built. For this space its inclination and proportions do not change, but it then becomes horizontal for 27 ft., termi-

[1] See Sir John Herschel's "Observations on the Entrance Passages in the Pyramids of Gizeh," in Vyse's *Pyramids of Gizeh*, vol. ii., pp. 107–109. The different angles of the entrance passages of other pyramids, and the circumstance that they were always closed at the completion of the buildings, show that the fact of this one's having pointed, at the period of its erection, to α Draconis, which was then the pole-star, is not to be regarded as more than accidental. Nevertheless, as above mentioned, the pyramids face the cardinal points.

Egypt.

nating at the entrance of an excavated chamber 46 ft. in length, and 27 ft. 1 in. in breadth, but of irregular and inconsiderable height. There is no doubt that this chamber was left unfinished at the closing of the pyramid. Beyond it the passage continues, opposite to where it entered the chamber, and extends horizontally 52 ft. 9 in. into the rock in the same direction.

Manetho calls the founder of the Great Pyramid Sûphis I., but Herodotus names him Cheops, and Diodorus Siculus Chembês, or Chemmis. His hieroglyphic name Shufu, or Khufu, according to the pronunciation of different dialects, was found, as before mentioned, by General Vyse, in the quarry-marks of one of the chambers above the King's, and occurs in the inscriptions of the neighbouring tombs of private individuals. The name of Num-shufu, Manetho's Sûphis II., occurs with that of Shufu, both in the quarry-marks and in the tombs: he appears to have ruled jointly with Shufu, and it is not improbable that he was also buried in this pyramid.

Second Pyramid.

The Second Pyramid stands at a short distance to the S.W. of the Great Pyramid, which does not very much exceed it in magnitude, though far superior in its construction. It has a base of 690 feet 9 inches square, and is 447 feet 6 inches in height, being more steep than its larger neighbour. It is chiefly remarkable on account of a great part of its casing having been preserved, extending about a fourth of the distance from the summit. The ascent is thus rendered very difficult, especially as when one has climbed on to the cased portion, he can see nothing of the lower part of the building, and thus feeling as if upon a pyramid in the air, is very liable to become dizzy. There are two entrances, both at the north side, from which, and other peculiarities, it appears probable that it was originally much smaller than now, and that, after its first completion, it was enlarged, and a new entrance and sepulchral chamber added. Herodotus and Diodorus Siculus ascribe its erection to a king whom the former calls Chephrên and the latter Kephrên, the brother and successor of the builder of the Great Pyramid. Diodorus says, that according to some he was named Chabryïs, and was the son of the latter sovereign. These are all variations of the name Shafra or Khafra, of an Elephantinite, Manetho's Sephrês, the second king of the Fifth Dynasty, who was about contemporary with Shufu.

Third Pyramid.

The Third Pyramid is almost in a line with the other two, but of much smaller dimensions, being only 203 feet in height, and 354 feet 6 inches square at the base. It is constructed beautifully, and in a costly manner, and in these respects is unexcelled, if equalled, by any other pyramid. The exterior was anciently cased altogether, or in part, with granite, but this has been generally torn off. General Vyse opened it, and found that it had been previously ransacked. In it he discovered a very beautiful sarcophagus (which was unfortunately lost at sea on its way to England), as well as part of a mummy-case, bearing the name of King Menkaura, and the body of a workman,[1] both of which are now in the British Museum. Herodotus and Diodorus ascribe the building of this Pyramid to Mykerinos, whom some, according to the latter, called Mecherinos; but Manetho makes it the work of Queen Nitôkris. The former sovereign is Manetho's Mencherês, the fourth ruler of his Fourth Dynasty, and the latter ends his Sixth Dynasty. This apparent inconsistency is explained, as the Chevalier Bunsen first remarked,[2] by the construction of the pyramid, which has two principal chambers, and was evidently enlarged after its first completion, so that we may fairly suppose that it is the sepulchre of both Mencherês and Queen Nitôkris.

Smaller Pyramids.

Near the three large pyramids are six smaller ones; three of these are near the east side of the Great Pyramid, and three on the south side of the Third Pyramid. They were probably the tombs of near relations of the kings who founded the great pyramids. The space around the pyramids is occupied by almost countless tombs, some built of stone, others excavated in the sides of the rock on which the pyramids stand, while others are simply pits with sepulchral chambers leading from them. The most interesting of these occupy a square bounded on the east by the Great Pyramid, and on the south by the Second, and are the sepulchres of the subjects of Cheops and other kings for the most part of the same period. These tombs, which are of inconsiderable dimensions in comparison to many at Thebes and elsewhere, are all built of stone, and have inclined walls, so as to resemble truncated pyramids. They usually contain several small chambers, the walls of which are decorated with most remarkable painted sculptures, pourtraying the every-day life of the Egyptians at that remote age, with short inscriptions of an explanatory character. The absence of representations of the gods and of the other subjects connected with religion, would lead one to suppose that at this time their belief was purer than at later periods, did not the inscriptions show this to be a false conclusion. Other similar tombs stand to the east and south of the Great Pyramid; and in the former direction are the principal sepulchral grottoes hewn in the side of the elevated rocky tract on which the pyramids stand. Some of these excavations bear similar representations to those of the tombs already mentioned. To the east of the Second Pyramid is the Great Sphinx, one of the most characteristic monuments of this wonderful necropolis. It is a recumbent andro-sphinx, or man-headed lion, 188 ft. 9½ in. in length,[3] hewn out of a natural eminence in the solid rock, some defects of which are supplied by a partial stone-casing, and the legs are likewise added. Steps lead to its front where are a sanctuary and tablets, but these are covered by the sand, which, after the hollow has been cleared, speedily fills it up again. Not far to the westward of the Sphinx is the remarkable excavation known as Campbell's tomb, chiefly consisting of a large pit surrounded by a trench. It was discovered by General Vyse, whose name is honourably connected with the most important discoveries in the necropolis of Memphis. The causeways leading to the Great Pyramid and to the Third, the former of which so greatly excited the admiration of Herodotus, are well worthy of a careful examination. The only pyramid which stands to the north of this group is that of Aboo-Ruweysh, which is in so ruined a condition as scarcely to deserve a visit. It lies about five miles to the north of the Great Pyramid.

Egypt.

Tombs.

Great Sphinx.

Pyramid of Aboo-Ruweysh.

Pyramids of Aboo-Seer.

Southward of the Pyramids of El-Geezeh, the first objects of interest are those forming the similar group of Aboo-Seer, of much smaller dimensions, the largest being about the size of the Third Pyramid. They are on the elevated edge of the Libyan chain, about seven miles from the Third Pyramid, and are four in number, three being large, and the fourth very small. The Northern Pyramid of Aboo-Seer appears to have been the tomb of Shura or Sôris, the first king of the Fourth Dynasty.

Pyramids of Sakkârah.

Pyramid of Steps.

About two miles further in the same direction, are the Pyramids of Sakkârah, the greatest and most remarkable of which is called the Pyramid of Steps. The tract around them appears to have been the principal burial-place of Memphis, from its nearness to the site of that city, and the number of the sepulchres. The Pyramid of Steps has a height of 196 feet 6 inches, and its base formerly measured at the north and south sides 351 feet 2 inches, and at the east and west, 393 feet 11 inches. Beneath it are numerous passages and a gallery, which must, for the most part, have been made subsequently to the completion of the structure.

[1] This body has been erroneously supposed to be that of king Mykerinos.

[2] *Egypt's Place*, vol. ii., p. 165, *et seqq.*, and 210, *et seqq.*

[3] Brugsch, *Reiseberichte aus Aegypten*, p. 336.

Egypt.

In the centre is a very lofty and narrow chamber, and near it a small one, which was lined with blue tiles. In the latter was an inscription containing the name and titles of a very early king, the former reading Ra-nub-rokhee, or Nub-rokhee-ra, which may correspond to Manetho's Necherôchis or Necherôphês, the name of the head of the Third Dynasty. In the tract between the Pyramids of Sakkârah and Aboo-Seer are the remains of the Serapeum, and the burial place of the Bulls Apis, both discovered by M. Mariette. They are inclosed by a great wall, having been connected, for the Serapeum was the temple of Apis. The tomb is a great subterranean gallery, whence smaller passages branch off, and contains many sarcophagi, in which the bulls were entombed. Not the least important result of this discovery is the certainty that Serapis was a form of Osiris, and that his name was Osir-hapi or Osiris-Apis,[1] as Sir Gardner Wilkinson had long previously suggested.[2] The other pyramids are of comparatively little interest. There are also some curious private tombs, among which may be particularized a large grotto excavated in the face of the rock overlooking the valley, which is remarkable for being vaulted on the principle of the true arch, but without a key-stone. It is of the time of Psammitichus II. of the Twenty-sixth Dynasty, being, as Sir Gardner Wilkinson remarks, one of the two earliest known examples of the arch in stone, though, as he adds, there are brick arches at Thebes of the time of Amenoph I. of the Eighteenth Dynasty.[3]

Site of Memphis.

The site of Memphis is marked by mounds in the cultivated tract to the east of the Pyramids of Sakkârah, and near the village of Meet-Raheeneh. Of the great temple of Ptah, or Hephæstus, its tutelary divinity, there are no remains above ground, except a few blocks of stone and some broken statues, one of which is a fine colossus of Rameses II., which stood most probably in ancient times before one of the principal entrances of the temple. It is of white chert and beautifully executed, representing the king in a standing posture. It has fallen to the ground, and part of its legs has been broken off; nevertheless it has suffered inconsiderable damage elsewhere, so as to be still one of the finest specimens of Egyptian art. The original height was more than 40 feet.[4] The site of Memphis being in the cultivated tract, and near the modern capitals of Egypt, its monuments have alike suffered from the destructive power of nature, and from the barbarism of those who have used them as quarries or defaced them from motives of fanaticism. The Pyramids have not escaped man's violence, but their vastness has generally defied his attacks.

Pyramids of Dahshoor.

At a distance of about five miles to the south of the Pyramid of Steps is the northernmost of the Pyramids of Dahshoor, an interesting group, of the history of which nothing certain is known. Two of these are of stone, and three of crude brick. The former exceed in size all the other Pyramids except the First and Second of El-Geezeh, and have remarkable chambers within them. The Northern Stone Pyramid has a base of 700 feet, and a height of 326 feet 6 inches, and has lost somewhat of its size, having originally measured 719 feet 5 inches, and 342 feet 7 inches. Some of the casing remains. It has an entrance in the northern face, leading to three chambers of similar construction to the Grand Passage in the Great Pyramid. The Southern Stone Pyramid is distinguished by the peculiarity of its form and by having two entrances, one in the eastern face and the other in the northern. The lower portion has an angle of 54° 14′ 46″, but the inclination then changes to 42° 59′ 26″. It has been supposed that it was suddenly completed, and had been originally intended to be much loftier, but the method in which the pyramids were built renders this unlikely; and it seems rather to have been given this form to gratify a whim of the founder, especially as the entrances in different faces afford a similar peculiarity. Its base is 616 feet 8 inches, and its height 319 feet 6 inches. At its southern side is a small brick Pyramid. The Northern and Southern Brick Pyramids of Dahshoor are to the east of those already described. They are in a very ruined state, being merely low mounds, and one cannot decide which of them is that of Asychis mentioned by Herodotus, for it can scarcely be doubted to be one of these.

It would be ungrateful to conclude this necessarily brief notice without mentioning to whom we are indebted for the most important discoveries made in the necropolis of Memphis. Among the earlier explorers were Belzoni, by whom the Second Pyramid was opened, Salt, and Caviglia, who made interesting excavations in the Great Pyramid and in its neighbourhood. But the late General Howard Vyse undertook a complete examination of the series of Pyramids, and having secured the valuable assistance of Mr Perring and an able staff, carried out this project with well-merited success. His most valuable discoveries have been noticed above, and it should be remembered that by the outlay of his private fortune he accomplished results that have been unexcelled by any expedition supported by the funds and the influence of a government. Dr Lepsius, the head of the Prussian Expedition, opened many tombs near the Pyramids of El-Geezeh and Sakkârah, and has published in his magnificent work (*Denkmäler aus Aegypten und Aethiopien*) the most interesting sculptures which they contain. M. Mariette, aided by the French government, recently discovered the Serapeum, and the tomb of the Bulls Apis. Many others have explored this great necropolis with various success.[5]

Ascent of the Nile.

The voyage up the Nile from Cairo may now be described. The traveller usually embarks at Boolâk or Masr El-'Ateekah. The objects of interest which he first sees have therefore been mentioned in speaking of those towns and of the environs of Cairo. Not far south of Masr El-'Ateekah the mountain and desert approach very near the river on that side, and soon after the wide opening of a valley is seen. Beyond it is a bold promontory of the eastern range which gradually recedes and then becomes parallel with the river for some distance, leaving but a narrow strip of cultivated land. Behind the village of Turâ, the ancient Troja, are the quarries named after it, and a little further to the south are those of El-Maasarah. These are great excavated chambers and passages, which are entered by large square apertures in the steep face of the mountain. Hence were taken the finer blocks of limestone, employed in the construction of the Pyramids of El-Geezeh. Tablets in both quarries record the quarrying executed under different sovereigns.[6] South of the quarries the character of the eastern bank continues unchanged, and presents no remarkable object until we reach the promontory of the sheykh Aboo-Noor, which will be subsequently mentioned. The western bank, on the contrary, is broad and fertile, abounding in villages, and above its palm groves rise in the dis-

Quarries of Turâ and El-Maasarah.

[3] *Modern Egypt and Thebes*, vol. i., pp. 368–9.

[4] This colossus is the property of the British Museum, but no steps have been taken to remove it to this country. As Sir Gardner Wilkinson remarks, "when the Turks have burnt it for lime, it will be regretted." (*Modern Egypt and Thebes*, vol. i., p. 373.)

[5] For an account of the Pyramids, or copies of the bas-reliefs in the tombs around them, see General Vyse's *Pyramids of Gizeh*, and the folio plates published under the same title; Sir Gardner Wilkinson's *Modern Egypt and Thebes*; Mrs Poole's *Englishwoman in Egypt*; Lepsius's *Denkmäler* and *Briefe aus Aegypten und Aethiopien*; Brugsch's *Reiseberichte aus Aegypten*, &c.

[6] Vyse's *Pyramids of Gizeh*, vol. iii., p. 93, *et seqq.*

tance the picturesque and massive forms of the long series of pyramids. Considerably beyond those of Dahshoor, which may be considered as the most southern of those in the Memphite necropolis, are the two Pyramids of El-Metâneeyeh, which are too small to be seen from the river, and yet farther the solitary Pyramid of Meydoom, commonly called the False Pyramid. This is a structure of considerable size, having a base of about 400 feet, and a height of about 310 feet. In consequence of blocks having been pulled off its sides for building purposes, it has the appearance of being built in two degrees, the lower of which is much greater than the upper, while the fallen stones around its base make it seem as if raised upon an eminence to increase its apparent size, and hence its name. The entrance has not been discovered, and as it is so far from Memphis it may have escaped the spoliation which the other pyramids suffered in ancient times.[1] Its position, rising alone above the rich valley and desert beyond, without any object by which to measure its size, render this pyramid, especially when seen from some distance across a broad part of the river to the north, a very striking and picturesque object. There is nothing else worthy of a visit on the western bank until we reach the town of Benee-Suweyf, about seventy miles by the course of the river from Cairo.

Pyramid of Meydoom.

Benee-Suweyf.

Benee-Suweyf is a busy town, being the port of the Feiyoom. A road leads hence to that province, in a north-westerly direction. After crossing the Bahr-Yoosuf, a branch of which waters the Feiyoom, we pass through the opening in the Libyan range, which leads to that province, leaving on our right the ruined brick Pyramid of El-Lâhoon, so called from an adjacent village.

Feiyoom.

The Feiyoom, including its lake, is a pear-shaped tract, its narrowest part being to the west, extending into the desert, and measuring in its greatest length about thirty miles, and in its greatest breadth about twenty. The part now cultivated is more than two-thirds of this extent from the east. At the north-western extremity is the great lake of El-Karn, which is long and narrow, and fills the northern portion of the valley. A branch of the Bahr-Yoosuf, as already mentioned, flows through the opening leading to the Feiyoom. This canal soon spreads into many streams, two of which, after joining into a single course, carry off the superabundant waters of the inundation into the lake of El-Karn, while they contribute with the others to irrigate the cultivable tracts.

Labyrinth.

The site of the famous Labyrinth first claims our notice after entering the Feiyoom. Its position may be known by a ruined crude brick pyramid, that of Hawârah, which is spoken of by both Herodotus and Strabo, and may be called the Pyramid of the Labyrinth. The remains of the Labyrinth itself, which had been previously known, were first carefully examined by the Prussian Expedition, headed by Dr Lepsius, in 1843, and much information was gained respecting it. The structure was so ruined, however, that the results were not as decisive as might have been hoped. Yet the plan was to some extent made out, and the building shown to have contained a great number of very small chambers, as ancient writers had said; and the discovery of royal names of the Twelfth Dynasty, particularly of Amenemha III. to whom Manetho ascribes the founding of the Labyrinth, leaves little doubt that this king was the Mœris who built the Labyrinth according to the classic writers. Notwithstanding, the name Mœris seems to have been applied to more than one sovereign, although there is little doubt that of these the most important was Amenemha III. His prenomen Ma-en-ra, probably corrupted into Ma-ra, appears to have originated Mœris, and is certainly sufficiently similar to afford some argument for the identity of Amenemha III. with Mœris of the Labyrinth. The use of this building has not been distinctly ascertained. Manetho indeed makes it to have been the founder's tomb, but it is most probable that he was buried in the pyramid, which, however, the Egyptian historian may have regarded as part of the Labyrinth, since it is evidently connected with that structure. It seems not improbable that the Labyrinth itself was a kind of council-house where the representatives, at first of the different kingdoms, and afterwards of the various nomes, met to transact the general business of the country, and where the records of these assemblies were preserved. Such an explanation seems best to suit the accounts of ancient writers and the character of the building, but it cannot be regarded as more than hypothetical.

Not far beyond the site of the Labyrinth is the capital of the province, usually called "El-Medeeneh" or "the City," and "Medeenet-El-Feiyoom," "the City" or "Capital of the Feiyoom," close to the mounds of the ancient Arsinoë, or Crocodilopolis. It is a small but flourishing town. The only monuments of antiquity in its neighbourhood are the remains at Beyâhmoo somewhat to the north, and the great broken tablet at Begeeg, at a smaller distance to the south. The former are two structures supposed by some to be pyramids, and the latter is a record of the time of Sesertesen I., which, since it bears the figures of several divinities, throws some light upon the religion of ancient Egypt at the remote period of his reign, which we may date as having commenced early in the twenty-first century before the Christian era. This is usually called an obelisk, but it must rather be regarded as a very tall and narrow stela or tablet, upwards of forty feet in height.

Lake Mœris.

In this part of the Feiyoom, to the north of El-Medeeneh, may be traced the remains of that remarkable hydraulic work the Lake Mœris, or, more properly, the Lake of Mœris, since Mœris is doubtless the name of the king by whose orders it was dug. A French engineer, of whom mention has been made already in this article, M. Linant, was the first to determine the position and character of this famous work of antiquity; and the results of his investigations are in accordance with the opinions of some who had previously noticed the subject in published works. To M. Linant certainly is due the merit of having settled a controversy of no little importance, and the Egyptian Society of Cairo deserves our thanks for the publication of his most interesting memoir.[2] The Mœris who gave his name to the lake was probably Amenemha III., the king who can scarcely be doubted to have been the founder of the Labyrinth. The object of the Lake Mœris was to regulate the irrigation of the Feiyoom, very anciently the Crocodilopolite Nome, and afterwards the Arsinoïte; and it was valuable on account of its fisheries. It seems rather to have deserved the name of a very large reservoir or broad canal than that of a lake. Notwithstanding the drying up of the Lake Mœris, the Feiyoom is still an important and fertile province. It produces very large quantities of grapes; and the fields of roses, cultivated for the sake of rose-water, present a remarkable appearance.

Lake of El-Karn.

The great Lake of El-Karn is perhaps the most interesting object in this part of Egypt. Its name, Birket-el-Karn, signifies "The Lake of the Horn," or "Projection," by

[1] Mr Harris of Alexandria remarked to the writer that the statement of Herodotus that Cambyses opened ancient sepulchres at Memphis (iii. 37) probably indicates the period at which most of the pyramids were rifled, since those opened in modern times have generally been found to have been carefully closed subsequently to their having been plundered.

[2] More than ten years ago the Egyptian Society was formed at Cairo, and afterwards the Egyptian Association. The former has published the *Mémoire sur le Lac Mœris*, noticed in the text, and reports of proceedings, and the latter, a useful volume of miscellanea. It is to be feared that both these societies have fallen into decay chiefly through the neglect of travellers, who would do well to encourage such useful institutions.

Egypt.

which an island is intended, and not its general form, as has been supposed. It is, as already stated, according to Sir Gardner Wilkinson, about 35 miles long, 7 broad at its widest part, and is not deep, as far as has been ascertained. The water is brackish and unwholesome, although derived from the Nile, which has at all seasons a much higher level. It is bounded on the south by tracts in a state of cultivation, or deserted for want of labourers though anciently cultivated, and on the north by the Libyan desert, above which rises a bold range of mountains; and it has a strange and picturesque wildness. Its northern shore was anciently cultivated, at least in part, but is now entirely waste. Near the lake are several sites of ancient towns, and the temple called Kasr-Kâroon distinguishes the most important of these. That temple, however, being devoid of sculpture, and doubtless of the Roman period, could not attract attention except in a region so barren of monuments. Not far from it are other remains of still less interest. After this cursory view of the Feiyoom we may return to the Nile and continue our southward course.

Not far south of Benee-Suweyf the eastern chain is washed by the river at the picturesque promontory of the sheykh Aboo-Noor, whose tomb stands on its summit. From this point as far as the town of Menfaloot the mountains on the east are close to the Nile, leaving a narrow space of cultivable land, or none at all, while on the contrary the western bank is far broader than before. For forty miles nothing remarkable attracts the eye except the lofty mounds of ancient towns, until one sees the well-proportioned minaret of a mosque in the large village of Semeloot, said to have been erected by the architect of the mosque of the Sultân Hasan at Cairo. Not far beyond, the river washes the picturesque cliffs of Gebel-et-Teyr, or the Mountain of Birds, part of the eastern range. Upon its summit stands a Coptic convent, called the Convent of the Virgin, Deyr-el-'Adra. One of the monks of this convent usually climbs down the steep face of the mountain by a dizzy path, and swims to the traveller's boat to solicit an alms as a fellow Christian; an appeal not to be slighted, however low one's opinion of the Coptic Church may be. In this part of Egypt we first begin to notice the entrances of grottoes in the face of the eastern mountains, but none of these for some distance are known to be of any interest. Not far beyond Gebel-et-Teyr is the town of El-Minyeh, on the western bank, a place wearing a cheerful aspect. Opposite El-Minyeh are quarries and sepulchral grottoes, the most remarkable of the latter being at a site called El-Kóm el-Ahmar, or "the Red Mound." These are of the time of the Fourth and Sixth Dynasties; but they have recently sustained so much damage that they do not repay a visit, except from one who is a student of hieroglyphics. The governor of El-Minyeh, an ignorant Turk, used these ancient tombs as quarries; and had it not been for the interference of Mr Harris of Alexandria, the more important grottoes of Benee-Hasan would have shared the same fate at his hands.

Gebel-et Teyr.

Grottoes of Benee-Hasan.

The first remarkable objects above El-Minyeh are the sepulchral grottoes of Benee-Hasan, just mentioned, which are inferior to none in Egypt for beauty and interest. They are excavated in the face of the eastern mountains, which are here very low and sloping, and separated from the river alone by a small extent of débris and desert, and a very narrow strip of cultivable land. There is a large island beneath, and the channel that runs between it and the eastern mountains is dry for a great part of the year. The grottoes are almost in a line near the summit of the mountain, and at no great height above the river. The two northernmost are remarkable for having porticoes, each supported by two polygonal columns of an order which is believed to be the prototype of the Doric. Most of the grottoes are adorned with sculptures and paintings which pourtray with eminent truthfulness and character the manners of the Egyptians of the remote period at which they were executed, for they are monuments of the Twelfth Dynasty, dating about B.C. 2000. The persons who were entombed here were governors of what must have been an extensive district, the chief town of which was doubtless not far distant. The tombs generally consist of a chamber of large dimensions, having sometimes a portico before it, and a niche with seated figures of the chief persons buried in it at the extremity, and pits leading to sepulchral chambers. The principal apartment is sometimes supported by pillars cut out of the rock, and vaulted. Its walls bear representations of the diversions of the occupant during his life-time, and of his varied occupations, in scenes depicting hunting, fishing, games, feasts, the processes of agriculture, and the like. The figures of beasts and birds, more especially the latter, are characterized by a remarkable fidelity and beauty, and there can be no doubt that Egyptian art had attained a greater excellence at this time than it possessed under the Fourth Dynasty, although it was not until the rule of the Eighteenth Dynasty that it rose to its highest perfection. A little to the south of these grottoes, in a ravine, is the Speos Artemidos, a small rock temple of Pasht, the Egyptian Diana, and some sepulchres of little interest.

A few miles to the south of the Speos Artemidos are two sites, one on either side of the river, which were marked, within the memory of persons now living, by most important monuments which have since been destroyed by the barbarism of the Turks. That on the right bank, near the large village of El-Ashmooneyn, the ancient Hermopolis Magna, was part of a magnificent portico, bearing the names of Philip Aridæus, Alexander Ægus, and Ptolemy Lagus, all that stood of the temple of Thoth; while on the opposite side of the river were considerable remains of the edifices of the town of Antinoë, founded by Hadrian. But while we regret the destruction of such interesting records, we must not charge either the Turks or the native Egyptians with all the mischief of this kind which is perpetrated, though our sorrow is increased by the reflection that to European travellers, not excluding the heads of more than one scientific expedition, must be charged no small share in the destruction or mutilation of the monuments. The apathy of the Turks, who cannot comprehend the value of the records of any but their own nation (and happy would they be could they blot out much of those annals); the vulgar desire of every traveller, especially of our own country and of America, to leave his name cut in every monument as a witness of his Vandalism, and to aid in its destruction by carrying off a fragment; the cupidity of the natives excited by this Frank custom of cutting pieces out of sculptures so as to produce the most deplorable results; and worst of all, the selfishness which has induced savans to take away part of a valuable monument to the ruin of the rest, in order to embellish a museum and gratify a patron,—all these causes have done more than time, or fanaticism, or the rage of an enemy, would have effected in a similar period.

A short distance south of Antinoë is the town of Mellawee on the western bank, and a little farther, but on the other side of the river, the promontory called the Gebel-esh-sheykh Sa'eed, which is honeycombed with grottoes, some of which are shown by their sculptures to be very ancient, but are so ill preserved as to require but a short examination. A little beyond, however, in the district of Tell-El-'Amârineh, or the Mound of El-'Amârineh, a small fertile tract where the eastern mountains recede, noted, like Benee-Hasan, for the turbulent and thievish propensities of its inhabitants, are very curious remains of a town. This place has been identified with Alabastron, or with the Psinaula of the Itinerary of Antoninus, but it is not improbable that it was deserted long before the Greek and Ro-

Tell-El-'Amârineh.

man rule in Egypt. It was the principal seat, or the capital of a foreign race of sun-worshippers who gained the chief power in Egypt towards the close of the Eighteenth Dynasty, and it was most likely destroyed when they were overthrown, and not subsequently rebuilt. In the mountain behind it are very curious sculptured grottoes, in which were buried the subjects of these foreigners, and from them we obtain much information respecting the people and their religion, a very pure form of sun-worship. The representations are chiefly of the king, his queen, and their children, distributing presents to the soldiers and others, of acts of worship to the sun, and of temples, as well as gardens and villas. Dr Lepsius has published a valuable series of these records in his great work.[1]

Deroot-esh-Shereef.

On the western bank of the Nile, a little to the south of Tell-El-'Amârineh is the small town of Deroot-esh-Shereef, supposed to be on the site of the Thebaïca Phylace, which was a strong place, guarding, as its name imports, the northern boundary of the Thebaïs. About 20 miles to the south is the town of Menfaloot on the same side of the river, which has a decayed appearance from the manner in which the stream has encroached upon, and washed away, part of it. Opposite to Menfaloot in the eastern range are extensive crocodile-mummy catacombs. There is nothing of note during the next 25 miles of the river's course, which is very winding, and therefore difficult to navigate, until we reach

Asyoot (Lycopolis).

the village of El-Hamra, the port of Asyoot. This town, the capital of Upper Egypt, or the Sa'eed, that is of the whole country above Cairo, and the residence of its governor, lies inland, about two miles from El-Hamra, in a richly cultivated plain. The town with its beautiful mosques, two of which, one of the Memlook style, and the other of the Turkish, are not unworthy of comparison with those of the metropolis, and its Constantinopolitan palace, surrounded on three sides by verdant fields, and having behind it a fine rounded spur of the western chain, which here, for the first time, is near the river, presents a picturesque appearance to one who approaches it. On entering Asyoot he is not disappointed, for the excellence of the goods and provisions sold in the well-built chief market, and the solid look of the houses, indicate activity and prosperity. And it is not a little remarkable that this was an important town at least 3500 years ago, and has thus outlived Thebes and Memphis, Tanis and Pelusium. The ancient Egyptian name was Ssut, or probably Ssiut, but the Greeks called it Lycopolis, on account of the worship of the dog-headed or wolf-headed divinity of the place. This was Hepuher, who seems to have differed from Anubis in his name alone. In the mountain behind Asyoot are some ancient grottoes, one of which is of great size, but their sculptures have unfortunately suffered much, and there is little to see in them after ascending the hill. The view of the valley and the town beneath is however an ample reward for the trouble. Thirty miles further by the course of the river, and on the eastern bank, is the village of

Kaw el-Kebeereh (Antæopolis).

Kâw el-Kebeereh where was anciently Antæopolis; the interesting remains of the temple of Antæus, which stood here early in the present century, have entirely disappeared through the encroachment of the river, and also, it is believed, from having been used as a quarry by the Turks. A few miles beyond this, the lofty part of the eastern range called the Gebel-esh-sheykh El-Hareedee, a famous Muslim saint, hems in the river on one side for a short distance. It soon however retires again, and the valley on that side becomes broader than usual. Here, a short way from the river, stands the small town of Akhmeem, the ancient Chemmis, or Panopolis. No remains of importance mark this site. About 22 miles farther by the course of the river, on the western bank, is the important

Girga.

town of Girga, which was, until a comparatively recent period, the capital of the Sa'eed. The rise of Asyoot, however, and the agency of the river which is gradually washing it away, have contributed to its decline, and it wears a dilapidated aspect. Near it must have been situated the very ancient city of This, whence the First and Second Dynasties took their name. Probably This stood not far from the sacred city of Abydos, the site of which is a few

Abydos.

miles from Girga, in a south-westerly direction, on the border of the Libyan desert, which is separated from the Nile by a broad tract of cultivated country. Two interesting edifices render Abydos worthy of a visit. The southernmost of these is a temple of Osiris, in which we find the names of Rameses II. and his father Sethee I., by whose orders it seems to have been constructed. It is so choked with sand and rubbish that little can be seen of its sculptures, and its plan can scarcely be ascertained; it is very desirable that it should be cleared. The other structure is believed by Sir Gardner Wilkinson[2] to be the famous temple of Osiris, the chief divinity of Abydos. It is smaller, and in a worse state of preservation than the other temple, and among its sculptures are the same names, those of Sethee I. and Rameses II. Hence was taken the famous list of Pharaohs, known as the Tablet of Abydos, which is now one of the most valuable objects in the British Museum.[3] In the desert near by are many sepulchres, which are chiefly remarkable on account of the interesting antiquities which have been discovered by clearing them out. The sanctity of Abydos as a reputed burial-place of Osiris, rendered this a favourite necropolis of the ancient Egyptians from very early times, and the extent of that of Memphis seems to have been partly owing to the same superstition.

Dendera (Tentyra).

At a distance of more than 40 miles from Abydos, but in nearly the same latitude, is the village of Dendera on the western, or rather southern, bank of the Nile. Before reaching it we pass the small town of Farshoot at the mouth of the great canal, called the Bahr-Yoosuf, and the large village of Hoo, marking the site of Diospolis Parva. Opposite the latter place are some sepulchral grottoes in the eastern chain, called those of Kasr-es-Seiyâd which is believed to occupy the position of Chenoboscion. They contain names of kings of the Sixth Dynasty, and that of the head of the Fifteenth, but the representations which occupy their walls are not of an unusual interest. Dendera, however, is remarkable as giving its name to the first well-preserved and unencumbered temple that is seen in a voyage up the Nile. This is the famous temple of Athor the Egyptian Venus, who presided over the town of Tentyra or Tentyris, the capital of the Tentyrite Nome. It stands on the mounds of the town about a mile and a half from the Nile. As this temple gives a good idea of Egyptian architecture as applied to such buildings, it must be described with some care, although but briefly.

The temple is surrounded by a great wall of crude brick, a stone portal in which faces its front. The portal is adorned with sculptures representing the Emperors Domitian and Trajan engaged in acts of worship before several divinities, whose names occur, as well as those of the sovereigns, in the accompanying inscriptions. A wall of brick has been recently built from each end of this portal to the front of the temple, thus forming a narrow passage terminating at the entrance of the portico. The portico is about 135 feet in width, and is one of the richest and most beautiful structures of the kind. It is supported by four and twenty columns, four deep, nearly fifty feet in height, and having a diameter of somewhat more than seven feet at the

thickest part. The capitals have a full face of Athor sculptured on each of their four sides, and above these a kind of shrine, or small temple. The portico is not seen to advantage in front, as it is buried to a considerable height in heaped-up rubbish, which partly conceals the intercolumniation that connects the three columns on each side of the entrance. But on descending into the interior, we are struck with the grandeur and justness of its proportions, and the richness of the sculptures which adorn its walls. It is, however, like the rest of the temple, of higher merit as regards its architecture than its sculpture, for the latter art had declined under the Greek and Roman rule to a much greater degree than the former. The sculptures are of the same kind as on the portal, representing offerings made by some of the earlier Cæsars; and on the ceiling are various mystical subjects, probably of an astronomical import, and the famous Zodiac from which an extravagant idea of the antiquity of the temple was deduced before hieroglyphics were interpreted. The greater part of the back-wall of the portico was the front of the temple before this portion was added. This inner part consists of three considerable chambers, an isolated sanctuary, and numerous small apartments. The first of these is a hall, supported by a double row of columns, three on each side, of a rather heavy form, for they have, beneath the capital formed of the block with the faces of Athor, and the shrine, another capital of a cup-shape. This hall is entered by a doorway in the middle of the back-wall of the portico, and passing through it we reach a second and third chamber of the same breadth but shorter, and then the sanctuary. The entrance of this chamber is in the same line with the others, but it is much narrower and isolated by a passage running round it. On each side of the chambers and passage are many small apartments, two passages to the exterior, and a staircase; and there are singular inclined passages in the walls, two of which are entered from the sides of the portico. All these chambers and passages, excepting the two last mentioned, are profusely covered with sculptures and inscriptions of a religious character, and chiefly depicting and narrating the piety of the sovereigns by whom the temple was erected. The royal names have not always been filled in, the rings remaining vacant; but when they have been sculptured, they are generally those of the last Cleopatra, and Cæsarion, her son by Julius Cæsar. The staircase already mentioned is on the left-hand side of the second chamber behind the portico, and conducts us to the roof of the temple. Here are a sort of chapel and some small chambers, one of which is very interesting, because its sculptures relate to the story of Osiris. The exterior of the temple is as completely covered with sculptures as the interior. Among the figures represented here are those of Cleopatra and Cæsarion; but they cannot be supposed to convey any resemblance, since they belong not alone to a conventional art, but almost to its lowest period. There are two smaller temples near the great temple of Athor, one of Isis, and the other of the kind called a Typhonium. Both are of the Roman time.

Kinè.

On the opposite side of the Nile, a little above Dendera, is the town of Kinè, between which and Arabia some traffic is carried on by the route through the desert to El-Kuseyr on the Red Sea. The best of the porous water bottles which are used throughout Egypt are manufactured here, as are the great water jars, called "bellâsee," which the women carry, at the large village of Bellâs, a few miles higher on the western bank. Opposite to Bellâs are the villages called Kuft or Kift, marking the site of the important town of Coptos, which was the emporium on the Nile of the Arabian and Indian trade under the Ptolemies; and somewhat to the south, the inconsiderable town of Koos, the ancient Apollinopolis Parva, which succeeded to the trade of Coptos, under the Muslims, until Kinè supplanted it. On the other, that is, the western bank, a little higher, is the small town of Nakâdeh, which the people call Nagâdeh, where are Roman Catholic and Coptic convents. A short distance beyond Nakâdeh are the northernmost of the remains of Thebes.

Thebes.

The monuments of Thebes do not present from afar the imposing appearance of the Pyramids of Memphis. Placed for the most part at a distance from the Nile, as well as from one another, and having on the western side the picturesque form of a much higher mountain than any near Memphis, rising behind them, they do not strike those who see them from the river or its banks. Most of them are not indeed visible from the Nile excepting when it is at its height. The stately colonnade of the temple of El-Uksur, on the very bank, is, however, not unworthy the magnificence of Thebes, and when one approaches the other monuments his utmost expectations are exceeded by the grandeur of El-Karnak, the beauty of the palace-temple of Rameses II, and the mysteriousness of the tombs of the kings. Nowhere else is the mythology, the history, the very life and manners of the Egyptians of old times so vividly brought before his eyes as in the sculptured and inscribed monuments of the capital of the greatest Pharaohs.

It will be necessary to say a few words as to the position of the principal monuments, and respecting the city which they adorned, before entering into a more detailed description. Thebes, or Diospolis Magna, is called in the hieroglyphic inscriptions Ap-t, or with the article prefixed, T-ap, and Amen-ei, or the abode of Amen. The Copts write the former name ταπε, which, according to the Memphite dialect, is pronounced Thaba,[1] and this explains the origin of the Greek Θῆβαι. In the Bible it is mentioned as נא אמון No-Amon, a name of difficult etymology. The date of its foundation is unknown, but remains of the time of the close of the Eleventh Dynasty have been found (*cir.* B.C. 2100), and it is reasonable to suppose it to have been at least as ancient as the commencement of that line, the first of Diospolite kings. Under the sovereigns of the Twelfth Dynasty it must have become a place of importance, but it probably declined during the troubles of the Shepherd period. With the Eighteenth Dynasty it attained its highest prosperity, and maintained it during the Nineteenth and Twentieth. To this period its greatest monuments belong. Then its decline evidently commenced; but from the manner in which Homer mentions it,[2] Thebes must have been still a great city in his days or not long before, for we can scarcely suppose that he did not speak of its condition in his own time, being doubtless unacquainted with the state of Egypt at the period of the Trojan war. After this it suffered severely from the barbarian violence of the Persians, and then of Ptolemy Lathyrus;[3] so that in Strabo's time the Thebans inhabited villages as now, and there was no longer a city.[4]

Monuments.

The monuments of Thebes, exclusive of its sepulchral grottoes, occupy a space on both sides of the river, of which the extreme length from north to south is about two miles, and the extreme breadth from east to west about four. The city was on the eastern bank, where is the great temple, or rather collection of temples, called after El-Karnak, a modern village near by. The temple of El-Karnak is about half a mile from the river in a cultivable tract. More than a mile to the south-west is the temple of El-Uksur, on the bank of the Nile. On the western bank was the suburb bearing the name Memnonia. The desert near the northernmost of the temples on this side almost reaches the river, but

Egypt.

soon recedes, leaving a fertile plain generally more than a mile in breadth. Along the edge of the desert, besides the small temple just mentioned as the northernmost, are the Rameseum of El-Kurneh, and that of Medeenet-Haboo less than a mile farther to the south-west, and between them, but within the cultivated land, the remains of the Amenophium, with its two gigantic seated colossi. Behind these edifices rises the mountain, which here attains a height of about 1200 feet. It gradually recedes in a south-westerly direction, and is separated from the cultivated tract by a strip of desert in which are numerous tombs, partly excavated in two isolated hills, and two small temples. A tortuous valley, which commences not far from the northernmost of the temples on this bank, leads to those valleys in which are excavated the wonderful tombs of the kings, near the highest part of the mountain which towers above them in bold and picturesque forms.

Temple of El-Uksur.

The temple of El-Uksur must be first described, as it is nearest of the edifices to the river, and but an appendage to the great group of El-Karnak. It takes its name from the small town of El-Uksur, or Abu-l-Haggâg, incorrectly called Luxor, which is built in and around part of it, thus injuring its effect, and rendering examination difficult. It differs from most Egyptian temples in not facing the river, but this is accounted for by its connection with the temple of El-Karnak, from the southern approaches to which a long avenue of sphinxes (now wholly ruined) leads to it, terminating at its entrance. This is a massive portal with wings, 200 feet in width, before which is a very fine obelisk of red granite. Its fellow, which stood on the western side, was removed by the French to Paris in 1831, and now adorns the Place de la Concorde. Both have beautifully cut hieroglyphic inscriptions. The height of that which remains is about 80 feet. It is adorned with three vertical lines of hieroglyphics on each side, in which are celebrated the praises of Rameses II. The other obelisk differs alone from this in being slightly shorter.[1] Close to the winged portal are three seated statues of red granite representing Rameses II.; a fourth has been destroyed. The wings of the portal are covered with sculptures of remarkable interest, representing occurrences in the war of Rameses II. with the Kheta or Hittites, in the early part of his reign.[2] On the left wing is depicted the defeat by the Egyptians, led by their king, of the confederate peoples under the walls of the stronghold called Ketesh,[3] which corresponds to Ashteroth-Karnaim mentioned in the Bible. The king, Rameses II., is represented, according to the Egyptian custom, of a gigantic size, standing in his chariot, which he has urged into the midst of the hostile force, whose warriors fall by his well-directed arrows. The Egyptians, on the other hand, sustain no loss, as in all such representations, which are therefore of a very partial character. It is difficult to understand how a warlike and civilized people could have thought the glory of a victory heightened by the imputation of cowardice to their adversaries, and that they should in such instances, to which the battle-scenes do not afford a single exception, have sacrificed truth to vanity. On the right wing is represented the camp of the Egyptian army during the same war. This has been sculptured over another scene, of which, owing to the falling out of the plaster with which it had been filled, part may be now seen. All these representations are in sunk relief, and beautifully executed.

The entrance to the temple is contracted by the construction of a modern wall, through the small door of which we enter a great court choked by the huts of the town, among which stands a mosque. It is surrounded by a double row of columns, the capitals of which have the form of the bud of the papyrus. A ruined portal with wings forms the end of this court, and with it commences the older part of the edifice, which has a more southerly direction; and its southernmost part in like manner turns a little more in that direction, that is, from the river, though not so remarkably. Some deviation was probably rendered necessary by the course of the Nile. The second court is much obstructed by rubbish, but free from huts; nothing is seen of it but a magnificent avenue of fourteen columns, having capitals of the bell-shaped flower of the papyrus, which led from its portal to that of the next court. The columns are about 60 feet in height, of fine form, and elegantly sculptured. They were raised by Amenoph III., whose name is the oldest which occurs on them and in the rest of the temple. Behind this is another court, which has a double row of columns on each side, and at its end a portico supported by columns four deep. This court is much ruined. Beyond it are several chambers of the time of Amenoph III., and in the midst of them an isolated sanctuary, the sculptures of which bear the name of Alexander Ægus, in whose reign it was built, in the place, no doubt, of one destroyed by the Persians under Cambyses or Ochus, as Sir Gardner Wilkinson remarks.[4] Most of these apartments are in a dilapidated state.

Temple of El-Karnak.

Although there is an approach to the temple of El-Karnak from that of El-Uksur, the grand entrance was towards the river, and from that entrance must commence a regular examination. This extraordinary assemblage of buildings consists of a great temple and several smaller structures, surrounded by a massive crude brick wall of enclosure. There are other remains similarly inclosed, which were connected with the great temple.

The grand entrance is through a propylon or portal with wings, more than 360 feet wide, for this is its measure above the rubbish which is piled up around it. It was never sculptured, nor was its surface smoothed. It presents, therefore, a rude appearance, and is much ruined, a great part of the left or northern wing having been demolished. The court, of which the propylon forms the front, measures 329 feet in width, and 275 in length, having on each side a gallery with a single row of columns, and a double colonnade, of which one column alone stands, formed an avenue from its entrance to that of the hypostyle hall beyond. On the right side a temple of older date interrupts the side gallery, extending 50 feet into the court. Its front is formed by a propylon, about 90 feet wide, on each wing of which Rameses III. is pourtrayed in the act of slaying prisoners before Amen-ra. The interior of this temple consists of a court which has on each side a row of Osiridean pillars, and at the end another row of such pillars with columns behind them. A hall or portico supported by eight columns is next to the court, and beyond it are other apartments. Nearly all the sculptures are of the reign of Rameses III., but the names of later sovereigns occur. On the other side of the great court is a small structure which may be called a chapel, or three chapels. The most interesting sculptures in this part of the group of temples are outside the eastern portion of the south wall of the great court, for here is the famous list of countries and towns subdued by, or tributary to, Sheshonk I., or Shishak, the head of the Twenty-second Dynasty. Among the names in the list is that of the kingdom of Judah, and those of several places in the dominions of Rehoboam and Jeroboam I.[5] At the end of the

[1] The inscriptions are given by Rosellini, *Monumenti Storici*, No. cxvii.

[2] See Rosellini, *Monumenti Storici*, Nos. civ.–cvii.; and above, section ii.

[3] Lepsius reads the first character of this name "k," from its being thus rendered by Hephæstion, in the name of one of the decans. *Chronologie der Aegypter*, i., p. 69.

[5] Champollion, *Lettres*, p. 99; Rosellini, *Monumenti Storici*, No. cxlviii.

court is a fine portal, the wings of which are much ruined. This is the entrance to the great hypostyle hall, the most magnificent work of its class in Egypt. Its length is 170 feet, and its width 329; it is supported by 134 columns, the loftiest of which are nearly 70 feet in height, and about 12 in diameter, and the rest more than 40 feet in height, and about 9 in diameter. The great columns, 12 in number, form an avenue through the midst of the court from the entrance, and the others are arranged in rows very near together on each side. There is a transverse avenue made by two rows of the smaller columns being placed farther apart than the rest. This great hall is therefore crowded with columns, and the effect is surprisingly grand. The spectator, being generally unable to see beyond those which are immediately around him, perceives the vast dimensions which, if viewed from a distance, might lose their effect. The forest of columns seems interminable in whatever direction he looks, producing a result unsurpassed in any other Egyptian temple. The partial ruin of its stone roof, and of some of the columns, render the hall the more picturesque, and make us wonder at the force which must have been expended in attempting to demolish it. This grand hall was built by Sethee I., the head of the Nineteenth Dynasty (*cir.* B.C. 1340), and sculptured partly in his reign and partly in that of his son and successor Rameses II., who has sometimes effaced his father's name to substitute his own. Thus it commemorates, not in its grandeur alone, but by its sculptures, the magnificence and power of these two great Pharaohs. The sculptures of the interior of the walls represent these kings making offerings to the gods, and the like subjects occupy the great columns. Far more interesting are those which adorn the exterior of the walls, and record the achievements of the same kings, those of Sethee I. being on the north wall, and those of Rameses II. on the south. The former are of much greater interest than the latter, as far as we can judge, and in this respect inferior to none in Egypt. The scenes on the north wall are arranged in three compartments, of which the upper one has been nearly destroyed. In them the king is represented of a gigantic size charging in his chariot, and putting to the rout his enemies, capturing their strongholds, and returning home in triumph. The chief nations are the *Kheta* or Hittites, the *Ruten* (*Luten*) or Lydians, who were apparently in those days not seated in Lydia but near to Mesopotamia, the *Shasu*, the people of the land of *Shari*, of *Remenen* (*Lemenen*) Hermon or Armenia, and of *Kanana* (*Kanaan*) or Canaan. Among the captured places is *Ketesh* or Ashteroth-Karnaim, which was in those days the most important stronghold between Egypt and Mesopotamia. There is also a long list of countries, cities, and tribes conquered or ruled by the king, among which we find *Nahareena*, that is Aram-naharaim, or Mesopotamia, *Kesh*, Kush, or Ethiopia, &c. The battle-scenes of Rameses II. on the south wall do not, as far as they are seen, equal these in interest. Here also is a list of the king's conquests and possessions, and on the west side of a wall which joins this one at right angles, forming the side of a court of the southern approach to the temple, is a representation of the capture of Askalena or Askalon, and an inscription recording a treaty between Rameses II. and the Kheta, concluded in the twenty-first year of the king's reign. The back of the hypostyle hall is formed by a ruined propylon bearing the name of Amenoph III., and then at a distance of about 50 feet is another propylon, entirely ruined. In the space between these propyla, which was a court, stands a beautiful obelisk of red granite, upwards of 70 feet high, raised by Thothmes I. The fragments of its fellow, which was more to the north, strew the ground. Behind the second of these propyla is another granite obelisk 92 feet high, and inferior in size to no other known Egyptian obelisk excepting that of San Giovanni Laterano at Rome. This great obelisk of El-Karnak is a monument of Queen Amen-numt who came to the throne in the year B.C. 1458 or 1457, and an inscription on its pedestal records the period which elapsed (nineteen months) from the time that it was begun to be cut in the quarry until its completion in Mesori (the twelfth month) of the queen's sixteenth year (B.C. 1442). The fellow of the great obelisk, which stood to the south of it, has been broken, and its fragments occupy its place. Beyond the great obelisk is the chief sanctuary, a structure almost entirely of granite, divided into two apartments, which was built under Philip Arrhidæus, in the place, no doubt, of one destroyed by Cambyses or Ochus. The space between the hypostyle hall and this sanctuary is extremely ruined, the huge stones being piled up in heaps as though an earthquake had overthrown the temple. But this destruction is doubtless to be ascribed to human violence, having probably been effected by the Persians, or Ptolemy Lathyrus, or both. Behind the sanctuary are fragments of a very ancient part of the temple bearing the name of Sesertesen I., the first king ot the Twelfth Dynasty, who came to the throne *cir.* B.C. 2080. Considerably farther is a large oblate building of the time of Thothmes III., which affords a remarkable example of architectural caprice, its columns having inverted shafts and capitals, and its cornices being likewise inverted. Behind this and a stone wall of enclosure are ruined chambers, and far beyond, directly behind the centre of the great temple, in the crude brick wall of enclosure is a handsome portal, never finished, bearing the name of Nectanebes I.

The southern approach to the temple of El-Karnak from that of El-Uksur is, as before mentioned, by a ruined avenue of sphinxes, which, when near the great structure, terminates, and two other avenues commence. The westernmost of these, which is of colossal rams, conducts to a temple situated not far to the south-west of the first court of the great temple, which we approach through a stately portal bearing in its inscriptions the name of Ptolemy Euergetes I. The front of the temple, before which was another avenue of rams, is a propylon, which is almost uninjured. Behind it is a court having a double row of columns on each side and at the end, and again behind this is a hall supported by eight columns, and many small chambers. This temple was dedicated to Khuns, the third member of the Theban triad. It was commenced under the Twentieth Dynasty, and continued by the later kings of the Twenty-first. A small edifice having sculptures of the time of the Greek and Roman rule stands on the west of the court of this temple.

The avenue of sphinxes, which branches off at the same place as does that of rams leading to the temple of Khuns, takes an easterly direction and terminates where another begins at right angles to it, which connects the southern courts leading to the great temple with a separate enclosure. The latter contains a lake which has the shape of a horse-shoe, and the remains of sacred structures. At the northern extremity of the avenue, which is of criosphinxes, is a propylon forming the front of a large court which terminates in a second propylon, which, like the other, is much ruined. Beyond this, but not in exactly the same direction, after a vacant space, the approach continues through two smaller propyla, the second of which is nearly destroyed. Each fronts a court, and at the end of the second of these courts was the great side entrance to the temple. The first and second propyla were, like the criosphinxes, monuments of King Har-em-heb, or Oros, of the Eighteenth Dynasty, and were partly built of materials of a temple or palace of the foreign sun-worshippers whom he overthrew. The third propylon is more ancient, since it bears the names of Thothmes III. and Amenoph II., as well as of subsequent kings: the age of the fourth is not certain: the name of Rameses II. occurs here, but it may

have been founded before his time. There is an enclosure in the angle formed by the third and fourth propyla with the great temple, which contains a sacred lake.

Adjoining the great crude brick wall of enclosure at its north-eastern portion is another containing the ruins of an important temple. The chief approach is through a stately portal of the Ptolemaic period, in the crude brick wall. The temple to which it conducted was very beautiful and costly, as we can judge by its remains, which show with how much violence it was destroyed. It seems to have been founded under the Eighteenth Dynasty. There are two small temples or chapels, one of the time of Achoris and the other of that of the supposed Amyrtæus and Nectanebes I. in the same enclosure. Another crude brick enclosure of small dimensions, near the south-east corner of that of the great temple, contains some unimportant remains of a small edifice.—The preceding brief description will convey some idea of the magnitude of the temple of Amen-ra at Thebes, with its appendages, since a mere enumeration of its various parts, with their date and a few of their most important sculptures, has occupied so much space. But no one who has not seen that wonderful assemblage of ruins can picture to himself the massiveness of its castle-like propyla, the grandeur of its hall of columns, the beauty of its great obelisk, and the sublimity of its heaped-up ruins. In that work of two thousand years, amid the records of the might and of the fall of Egypt, the past ushers up a long train of great historic figures, from Sesertesen I. and the Shepherd times to Rameses II. the conqueror, to Shishak, who subdued Judah, to the Persian conquest, and to the final ruin of the "City of Thrones" by Ptolemy Lathyrus, after its last noble struggle. In the great hall, undisturbed by any living thing, we seem to hear the sacred music of the priests and to see the pomp of the returning victor as he passes on to the sanctuary to pay his vows. And when we stand before the lofty obelisk rising above the mass of ruins and pointing heavenwards, like the monument of a devoted city and people, we see the fulfilment of God's decree, "No shall be rent asunder."[1]

In describing the monuments on the western bank at Thebes, it will be best first to notice the remarkable temples and remains of temples, excepting the two small ones among the tombs, and then to give some account of the necropolis. It has been already mentioned that the great suburb which stood here was called the Memnonia.

Setheum.

Beginning our examination from the northward, the first object of interest is the Setheum, a small temple of Sethee I., which the natives call Kasr-Er-Rubeyk, at the ruined village of El-Kurneh. A portico originally supported by ten columns, of which two have fallen, extends along the whole front of the building. Three entrances lead to the interior of the temple: the middle one of these is the door of a hall having twelve columns. From this apartment we pass into several small chambers, which are of no particular interest, like the ruined chambers which we enter from the northern door. The southern door is the entrance of a separate part of the edifice, which contains a small hall supported by two columns, and three chambers behind it, the middle one of which was a sanctuary or chapel, devoted, as its sculptures show, to the worship of Rameses I., the father of Sethee I. The inscriptions of the temple tell us that it was dedicated to Amen-ra by its founder Sethee I., and continued by his son Rameses II., and his grandson Menptah.

Rameseum of El-Kurneh.

The great temple of Rameses II., which may be called the Rameseum of El-Kurneh, but is commonly though incorrectly known as the Memnonium, is situated at a distance of about a mile to the westward of the Setheum, and is like it on the edge of the desert, which here is much farther from the Nile than it is near the other temple. Notwithstanding that its condition is so much more ruined than that of other edifices here, the beautiful architecture of what remains, and the historical interest of its spirited sculptures, render it altogether second alone in its attractions to the great pile of El-Karnak. A propylon, 225 feet in width, of which a great part has been thrown down, forms the front of the edifice. Through its portal we enter a spacious court, 180 feet in width and 142 in length. It had originally a double colonnade on either side, every column of which has been destroyed, while the side walls have been entirely demolished, and the end wall partially. On the back of the propylon are sculptured a battle and other scenes of a campaign in the king's eighth year. In this court is one of the most wonderful objects at Thebes, a colossal statue of Rameses II., broken in pieces, exceeding in its weight and equalling in its dimensions any other known Egyptian statue. It was of a single block of red granite, and must have been transported hither from the quarries of Syene, notwithstanding that its weight was, according to Sir Gardner Wilkinson's computation, about 887 tons, $5\frac{1}{2}$ hundredweight.[2] It was 60 feet in height, representing the king seated on his throne, and was placed on the left side of the entrance to the second court. Of that court, happily, there are more remains than of the first. Its width was about 170 feet and its length about 140, so that it was not much smaller than the other court. It had a double colonnade on each side and at the end, and but a single colonnade at the front. All these were of columns having capitals of the form of the papyrus bud, excepting eight of the ten forming the front row, that is, all of that colonnade but the two extreme columns, and, in like manner, the corresponding ones of the opposite row, which were square Osiridean pillars, or pillars formed of a square block, having in front a figure of Osiris. Many of the columns and pillars have been demolished, nevertheless those which yet stand enable us to judge how magnificent this part of the temple must have been. On what remains of the front wall of the court, that is, on its northern half, are very remarkable sculptures which must not be passed by unnoticed. Here is a great scene representing a battle between the Egyptians, led by Rameses II., and the Kheta or Hittites, near the strong city of Ketesh or Ashteroth-Karnaim. The king of Egypt is pourtrayed routing the chariots of the enemy, who flee in disorder towards Ketesh, across a double moat, beyond which and beneath the city a strong force of regular infantry endeavours to protect their retreat. This was doubtless the decisive action of the campaign against the confederates, which must be regarded as the most important of those which distinguished the reign of Rameses II.[3] Higher up on the same wall is a procession of priests bearing small statues of kings, the first of which is that of Mênês, the earliest sovereign of Egypt, the second of Munt-hotp, a king of the Eleventh Dynasty, and the subsequent ones of the kings of the Eighteenth and Nineteenth Dynasties as far as Rameses II., with whom the series terminates.[4]

Next to the second court is a hypostyle hall, which is the most admirable part of the temple. It measures 100 feet in length and 133 in breadth, and originally contained forty-eight columns in eight longitudinal rows, each consisting of six columns. A central avenue is formed by twelve lofty columns, about 36 feet high, which have capitals of the shape of the papyrus-flower, while the columns on each side, about 24 feet high, have capitals of the shape of the bud of the same flower. The elegance of the form and the justness of the proportions of all these columns is not equalled in any other Egyptian temple, and render this one

Egypt.

of the most beautiful structures of its kind. Happily although much injured, it has suffered less from violence than the first and second courts. On its front wall, to the left as one enters, are curious sculptures, representing the rout of a hostile force and the capture of a town, the walls of which the Egyptians ascend by means of scaling-ladders: Rameses II. and six of his sons lead the army. On the end wall are religious subjects, and a series of the sons and daughters of Rameses II., whose legitimate offspring they seem to have been, twenty-six in number, twenty-three sons and three daughters. At the temple of Wadee-es-Suboo'a in Nubia were represented, according to Lepsius, a much larger number of children of this king.[1]

Beyond the hypostyle hall are two smaller chambers, the first of which is entered by a doorway in the middle of the end wall of the hall. It is supported by eight columns, and has on its walls representations of mythological or religious subjects. It is chiefly remarkable, however, for its astronomical ceiling, one of the most precious records of ancient Egyptian science.[2] Behind this is a ruined chamber, which seems to have been of the same dimensions. The other apartments which must have adjoined these are entirely demolished. The description which Diodorus Siculus gives from Hecatæus of Abdera of the Tomb of Osymandyas agrees best with the Rameseum of El-Kurneh; and his mention of the sacred library is in accordance with the character of the sculptures of the first chamber beyond the hypostyle hall, as well as with the statement in several papyri that they were written by the scribes in this temple, in which, or attached to which, was a kind of college.[3]

Amenophium.

To the south-east of the Rameseum of El-Kurneh, at a distance of less than half a mile, a mound, just within the cultivable plain, marks the site of a magnificent temple of Amenoph III., which may be called the Amenophium, and which, there is reason to believe, was destroyed by Cambyses. Of the obelisks and colossi which stood on either side of the approach to the Amenophium, all are thrown down except the two gigantic statues, one of which is known as the Vocal Memnon. The latter, indeed, was broken, but afterwards restored. These colossi stand about a quarter of a mile to the south-east of the mound where are the scanty remains of the temple. They are of hard gritstone, monolithic, and about 47 feet in height, with pedestals about 12 feet high. They represent a king, Amenoph III. (as their inscriptions attest), seated on his throne. Smaller though colossal standing statues of the king's mother, Queen Mutem-wa, and of his wife, Queen Taya, rest against the space between the sides of the throne and the legs of the great statues, one at either extremity; while there are remains of another statue of Queen Taya, of smaller size, which stand between the feet. The colossi are a little less than 60 feet apart; a distance judiciously chosen, so that they should neither seem smaller than they actually are, by being placed too far from each other, nor should be so near as to appear but a double statue. As they now stand in the midst of the fields, far away from human habitations or ancient temples, bearing in their mutilated forms the marks of successive ages, as well as of barbarian violence, calling up the story of Egyptian greatness so long departed, and the poetic traditions of Greece once believed, reminding us of those who have stood here before the rising of the sun to hear the mysterious sound, and have themselves passed away with their religion and their power, while they have kept their places as watchmen overlooking the change of empires and of faiths, they are not dumb, and their inarticulate voice tells us more than did that of Memnon in old times.

Vocal Memnon.

The Vocal Memnon is the more northern of the two, and is, as before mentioned, imperfect. It was broken in the midst either by the barbarism of Cambyses, or by an earthquake, more probably the former,[4] but long afterwards repaired. It presents in consequence a very shattered appearance, and the other colossus gives us a better idea of what the pair must anciently have been. Many Greek and Latin inscriptions on the Vocal Statue record the visits of those who were with Hadrian, and of others, and relate that they heard the voice of Memnon. There is thus satisfactory evidence to show that some sound was frequently heard here at sunrise; and the only dispute is whether it was produced by a physical cause, or was an imposture of the priests. The former appears to be the more probable view, as such a deception could hardly have been carried on so long without detection; and its being a natural occurrence does not seem impossible from the examples we have of sounds resembling that which is described as having been heard here by the ancients.

Medeenet-Haboo.

Less than half a mile from the mound of the Amenophium, in a south-westerly direction, within the desert, is the group of temples known as those of Medeenet-Haboo. This name is that applied by the Arabs to a town, which appears to be that called Papa in the Roman times. The ruins of its houses obstruct the temples, more especially the larger of the two. The smaller temple may be first described, since it is nearer to the river, to the eastward of the other. We first enter a ruined court which was never completed, and which had a colonnade whereof two columns alone yet stand, at its end, a little before the first propylon of the temple, which bears the name of Ptolemy Lathyrus and that of Auletes among the sculptures of its gateway. Beyond this is a court which had a colonnade on each side, and a propylon, much smaller than the other, at the end. Most of its columns have fallen, and the propylon has also suffered much. On the latter we see the names of Tirhakah the Ethiopian, and later sovereigns. Beyond this is another court, and then the chambers of the temple. The chief of these is an isolated sanctuary, with a gallery around it having square pillars and fluted columns like those of certain of the tombs at Benee-Hasan. The sanctuary is ornamented with sculptures of sovereigns of the Eighteenth Dynasty, including Queen Amen-numt.

Small temple.

Palace.

To the south-west of this temple is a very remarkable structure, which differs in its use and architecture from any other ancient monument in Egypt. It is the only palace that has been preserved, although the temples have been supposed to have been likewise palaces, or palace-temples.[5] After passing between what seem to have been lodges, we arrive at the main part of the palace of Rameses III. This consists of two towers on each side of a court ending in another tower, beneath which is a gateway conducting to the great temple. On the front of each of the two towers first mentioned Rameses III. is represented slaying his enemies before Amen-ra, and below is a series of captured chiefs. The inscriptions that remain tell us that these are the chiefs of the Kheta, or Hittites, the Amari, or Amorites, the Tokkaree, or Carians, the Khairetana (Khairetaan) of the sea, or Cretans (Cherethim), the Tuirkha (Tuirsha) of the sea, and of other peoples whose names are partly or wholly destroyed. On the walls of the chambers are curious sculptures representing the private life of Rameses III. Among

[2] *Id.*, bls. 170, 171.
[3] *Chronologie der Aegypter*, i., p. 39, 53.
[4] Comp. Paus. *Attic.* i., 42.
[5] The size and character of the only chambers in the temples which could have been used for habitation render it most improbable that any but priests and scribes resided in them, except perhaps on the occasion of some important ceremonies which may have lasted a considerable time; and it is most likely that the royal abodes were usually extensive pavilions constructed of no stronger materials than the houses of the people, and this view the representations of the tombs seem to support. The temples, however, were called palaces.

these the king is pourtrayed playing at a game like that of draughts with one of his daughters, while another stands by him. They are all represented naked.

Great temple.

The great temple of Medeenet-Haboo is directly behind the palace through which was, as already mentioned, the approach to it, and is a monument of the same king Rameses III., a sovereign inferior alone as a conqueror to Rameses II., the greatest ruler of Egypt. Both the magnificence of its architecture, and the high interest of its sculptures, render it one of the most interesting edifices at Thebes. It is much obstructed by the remains of the town that formerly stood in and around it.

The first propylon cannot be less than 200 feet wide. It is partly destroyed, and much of it is hidden by the remains of the town. On its wings the king is represented slaying prisoners before the gods, and acts of worship are also depicted. The court, of which this propylon is the front, is about 110 feet in length and about 135 in breadth, and has a colonnade on either side, forming a gallery. The gallery on the right side consists of seven Osiridean pillars, that on the left, of eight columns having capitals of the form of the papyrus-flower, affording a remarkable example of the irregularity of Egyptian architecture. This court is nearly filled with rubbish. At its end is a second propylon, on the left wing of which Rameses III. is represented bringing captives of the Tokkaree, or Carians, before Amen-ra. Passing through the granite portal of this propylon we enter the second or peristyle court, the finest part of the temple. This court measures about 123 feet in length and about 133 or somewhat more in width, thus exceeding in size the first court, contrary to the usual practice of ancient Egyptian architects. It has a single colonnade at the front and on either side, and a double one at the end. The colonnade at the front and that facing it are each of eight Osiridean pillars, while that behind the latter is of columns with capitals of the papyrus-bud, and the side colonnades consist each of five similar columns, one of which, on the left side, has fallen. Happily this court is less choked than the other, and one can form some idea of its original splendour. The Christian inhabitants of the town, the ruins of whose church are seen in the court, defaced many of the sculptures, and particularly the Osiridean pillars; nevertheless the general effect is not lost, and one is struck by a simple grandeur, which is unsurpassed in any similar Egyptian structure. The sculptures of the walls are of especial interest, and a short description of them must therefore be given. On the back of the left wing of the propylon a series of sculptures relating to the wars of Rameses III. commences and extends along the wall on the left side of the court. The rout of the Rebu or Lebu, perhaps Libyans, is depicted, the triumphant return of the king, the bringing of prisoners before him on the field of battle, and the like; and besides these are subjects pourtraying ceremonies. On the right side-wall is a curious representation of the celebration of the Panegyry of Amen-ra Generator, which, from the detail in which it is given, affords us considerable insight into the manner in which such solemnities were kept.[1] On the end-wall, and on part of each side-wall are depicted the many children of Rameses III. A door in the wall first mentioned conducts to the inner part of the temple, which occupies but little less space than the two courts just described. It is entirely choked with rubbish.

The sculptures of the exterior of this edifice next claim our attention, none of which have been mentioned excepting those which occupy the face of the first propylon. On the north, or rather north-eastern wall, is a remarkably interesting series of sculptures commemorating the events of foreign wars of Rameses III., and equalling in the importance of their subjects and the boldness with which they are executed any other records of the kind in Egypt. In the first representation, which is to the extreme right, we see Rameses III. going to war; in the second is depicted the rout of a people called the Tamhu; and in the third, prisoners of the Tamhu and Mashuash are brought before the king, while scribes count the hands, &c., which have been cut from the slain, showing their number to have been 12,535. Then weapons, probably taken from the enemy, are counted. The next scene is very complicated, and represents a great battle with the Tokkaree or Carians, whose army is defeated by the Egyptians. The Tokkaree fight in chariots of two horses and in waggons drawn by four oxen. Mercenaries or allies who are called Khairetana, (Cherethim or Cretans) fight in the army of Egypt. The scene which follows this is one of the most spirited of Egyptian sculptures, and if compared with the similar Assyrian bas-reliefs in the British Museum, shows the great superiority of the best Egyptian art over that of Assyria. The king, who, is passing through a marshy country in his chariot, encounters three lions, and having smitten two of them with his javelins, turns round to meet the third which is about to spring. The next subject is the most remarkable of the series, since it represents a sea-fight, in which the Egyptian fleet defeats that of the Khairetana (Cretans) and the Tokkaree (Carians), while Rameses and his army aid their countrymen from the shore. Thus, probably, the Cretans, in whose navies the Carians fought of old, according to a tradition which Herodotus relates, lost the empire of the sea. Rameses then receives the praises of his warriors, and the hands of the slain are brought before him and numbered. Next he leads prisoners, who are of the Tokkaree and Rebu, before the gods of Thebes. The other battle-scenes of the series represent the capture of strong places, the carrying away of captives, &c. On the end wall the king is pourtrayed setting forth on an expedition, and on the other side-wall, the south-west, is a long calendar, which appears to occupy the whole wall. Not far from the Rameseum, to the southward, is a small Ptolemiac temple containing three chambers. Farther in the same direction is a great lake, over which in ancient times it is probable that the funeral processions passed. At more than half a mile in a south-westerly direction from the lake is another small temple of Roman times, having an isolated sanctuary and other chambers.

Necropolis.

The private and royal tombs must now be briefly noticed, but from their great number, and the variety of the paintings which occupy their walls, it will not be possible to give as detailed an account of them as has been given of the other monuments. Two temples which are situate in the necropolis likewise require a notice. The tombs, as before mentioned, occupy some of the space at the foot of the mountains, or are excavated in their sides towards the valley, and in two isolated hills, excepting the tombs of the kings, which are cut in the sides of two secluded valleys to the westward.

Beginning from the north, we first see the entrances of grottoes in the low spur of the Libyan chain behind the Setheum. Several of these have a series of square apertures, leaving pillars to support the roof, so as to form a kind of portico, behind which is a chamber or chambers, having pits, from which open other chambers for sepulture. Some grottoes here, and others extending towards the Rameseum, are inhabited by the people of El-Kurneh, whose village is ruined. At the foot of the mountains, as well as on their least steep sides, here and throughout the necropolis, are the entrances of many mummy-pits. On the spur above mentioned are brick pyramids, for the most part nearly destroyed; and in the wide tract beyond, where the mountains recede, are very remarkable sepulchres of the time of the

Egypt.

Twenty-sixth Dynasty. These are extensive excavations, profusely sculptured almost entirely with hieroglyphics, having before their entrances open courts hewn in the rock, and entered through crude brick propyla, from which walls of enclosure of the same material extend around the courts. The largest of these, and indeed of all those known at Thebes, is the tomb of Pet-amen-apt, a priest whose date is not fixed, but who probably lived towards the close of the Twenty-sixth Dynasty, or the beginning of the Twenty-seventh.[1] Sir Gardner Wilkinson says that "the area of the actual excavation is 22,217 square feet, and with the chambers of the pits 23,809, though, from the nature of its plan, the ground it occupies is nearly one acre and a quarter."[2] Almost all the passages and chambers are covered with hieroglyphic inscriptions on a small scale, and the few sculptures are of a religious character. At the end of the Asaseef is a temple which was approached by a very long avenue of sphinxes now entirely demolished. The temple is at the base of a steep cliff, and is partly excavated in the rock, and partly built of masonry. The latter portion is almost wholly destroyed. A portal of red granite which formed its entrance yet remains, bearing the name of Thothmes III., cut over the erased name of Queen Amen-numt. A second granite portal stands behind this, almost close to the rock. At some distance to the left of this are two small chambers, one of which is remarkable for the form of its roof, which is vaulted by horizontal stones, of which the two uppermost meet in the centre, all being cut internally, so as to form an arch. The excavated part of the temple consists of an oblong chamber of moderate dimensions, another of smaller size with a cell on each side, and at the end a sanctuary. All these, excepting the sanctuary, are of the time of Queen Amen-numt and Thothmes III., and have vaulted roofs. The sanctuary bears the sculptures of Ptolemy Physcon, affording a remarkable contrast to the delicate style of those of the chambers which lead to it, and it is flat-roofed.

The isolated hill of the sheykh 'Abd-El-Kurneh (probably a mistake for 'A'bid-El-Kurneh, meaning "the Devotee of El-Kurneh"), presents a singular appearance from the plain, since on that side it is honeycombed by the entrances of tombs. Several of these, like some of those first mentioned, have porticoes before them hewn in the rock, and many have very interesting paintings, representing scenes of domestic life, funeral ceremonies, arts, trades, &c., in their upper chamber or chambers. These have, unfortunately, suffered greatly from the cupidity of the natives, and the disgraceful Vandalism of European travellers. Farther towards Medeenet-Haboo is a similar isolated hill, called Kurnet-Mara'ee, which contains a few grottoes of the same description, and in the valley between this and the main mass of mountain are many other interesting grottoes. At one extremity of this valley, at some distance behind the Rameseum, is a small edifice with a high enclosure of crude brick walls. It is a temple of Athor, of the Ptolemaic period, and has a small portico and three chambers, in one of which, the side chamber to the left, is a curious sculpture, of which the subject is the judgment of a soul by Osiris. Hence we may infer that this was a temple attached to the necropolis, and the same appears to have been the case with that of the Asaseef, since there deceased royal personages receive divine honours, as though they were buried in the vicinity. Beyond the other extremity of this valley is the secluded valley, called that of the Tombs of the Queens from its containing the sepulchres of queens and princesses of the Eighteenth, Nineteenth, and Twentieth Dynasties. These are similar to the tombs of the kings, which are next to be described, but are not large, nor are the subjects on their walls, which seem generally of little interest, well preserved.
